$$\begin{aligned}K &= \tfrac{1}{2}\left[\tfrac{1}{2}(2.2\,\text{kg}) + 4.8\,\text{kg}\right]\left(\frac{1.2\,\text{m}}{2\pi}\right)^2\omega^2 \\ &= \left(0.1076\,\text{kg}\cdot\text{m}^2\right)\omega^2\end{aligned}$$

Substitute in equation (1) and solve for ω:

$$\left(0.1076\,\text{kg}\cdot\text{m}^2\right)\omega^2 - 75.75\,\text{J} = 0$$

and

$$\omega = \sqrt{\frac{75.75\,\text{J}}{0.1076\,\text{kg}\cdot\text{m}^2}} = \boxed{27\,\text{rad/s}}$$

(*b*) Noting that the moment arm of each portion of the rope is the same, express the total angular momentum of the system:

$$\begin{aligned}L &= L_\text{p} + L_\text{r} = I_\text{p}\omega + M_\text{r}R^2\omega \\ &= \left(\tfrac{1}{2}M_\text{p}R^2 + M_\text{r}R^2\right)\omega \qquad (2) \\ &= \left(\tfrac{1}{2}M_\text{p} + M_\text{r}\right)R^2\omega\end{aligned}$$

Letting θ be the angle through which the pulley has turned, express $U(\theta)$:

$$U(\theta) = -\tfrac{1}{2}\left[(L_{1i} - R\theta)^2 + (L_{2i} + R\theta)^2\right]\lambda g$$

Express ΔU and simplify to obtain:

$$\begin{aligned}\Delta U &= U_\text{f} - U_\text{i} = U(\theta) - U(0) \\ &= -\tfrac{1}{2}\left[(L_{1i} - R\theta)^2 + (L_{2i} + R\theta)^2\right]\lambda g \\ &\quad + \tfrac{1}{2}\left(L_{1i}^2 + L_{2i}^2\right)\lambda g \\ &= -R^2\theta^2\lambda g + (L_{1i} - L_{2i})R\theta\lambda g\end{aligned}$$

Assuming that, at $t = 0$, $L_{1i} \approx L_{2i}$:

$$\Delta U \approx -R^2\theta^2\lambda g$$

Substitute for K and ΔU in equation (1) to obtain:

$$\left(0.1076\,\text{kg}\cdot\text{m}^2\right)\omega^2 - R^2\theta^2\lambda g = 0$$

Solving for ω yields:

$$\omega = \sqrt{\frac{R^2\theta^2\lambda g}{0.1076\,\text{kg}\cdot\text{m}^2}}$$

Substitute numerical values to obtain:

$$\omega = \sqrt{\frac{\left(\frac{1.2\,\text{m}}{2\pi}\right)^2\left(0.6\,\text{kg/m}\right)\left(9.81\,\text{m/s}^2\right)}{0.1076\,\text{kg}\cdot\text{m}^2}}\,\theta = \left(1.41\,\text{s}^{-1}\right)\theta$$

Express ω as the rate of change of θ:

$$\frac{d\theta}{dt} = \left(1.41\,\text{s}^{-1}\right)\theta \Rightarrow \frac{d\theta}{\theta} = \left(1.41\,\text{s}^{-1}\right)dt$$

Integrate θ from 0 to θ to obtain:

$$\ln\theta = \left(1.41\,\text{s}^{-1}\right)t$$

Transform from logarithmic to exponential form to obtain:

$$\theta(t) = e^{\left(1.41\,\text{s}^{-1}\right)t}$$

Differentiate to express ω as a function of time:

$$\omega(t) = \frac{d\theta}{dt} = \left(1.41\,\text{s}^{-1}\right)e^{\left(1.41\,\text{s}^{-1}\right)t}$$

Substitute for ω in equation (2) to obtain:

$$L = \left(\tfrac{1}{2}M_\text{p} + M_\text{r}\right)R^2\left(1.41\,\text{s}^{-1}\right)e^{\left(1.41\,\text{s}^{-1}\right)t}$$

Substitute numerical values and evaluate L:

$$L = \left[\tfrac{1}{2}\left(2.2\,\text{kg}\right) + \left(4.8\,\text{kg}\right)\right]\left(\frac{1.2\,\text{m}}{2\pi}\right)^2\left[\left(1.41\,\text{s}^{-1}\right)e^{\left(1.41\,\text{s}^{-1}\right)t}\right] = \boxed{\left(0.30\,\text{kg}\cdot\text{m}^2/\text{s}\right)e^{\left(1.41\,\text{s}^{-1}\right)t}}$$

Chapter R
Relativity

Conceptual Problems

1 • You are standing on a corner and a friend is driving past in an automobile. Each of you is wearing a wristwatch. Both of you note the times when the car passes two different intersections and determine from your watch readings the time that elapses between the two events. Have either of you determined the proper time interval? Explain your answer.

Determine the Concept In the reference frame of the car both events occur at the same location (the location of the car). Thus, your friend's watch measures the proper time between the two events.

2 • In Problem 1, suppose your friend in the car measures the width of the car door to be 90 cm. You also measure the width as he goes by you.
(*a*) Does either of you measures the proper width of the door? Explain your answer. (*b*) How will your value for the door width compare to his? (1) Yours will be smaller, (2) yours will be larger, (3) yours will be the same, (4) you can't compare the widths, as the answer depends on the car's speed.

Determine the Concept The proper length of an object is the length of the object in the rest frame of the object. The proper length of a meter stick is one meter.

(*a*) Because the door is at rest in the reference frame of the car, its width in that frame is its proper width. If your friend measures this width, say by placing a meter stick against the door, then he will measure the proper width of the door.

(*b*) In the reference frame in which you are at rest, the door is moving, so its width is less than its proper width. To measure this width would be challenging. (You could measure the width by measuring the time for the door to go by. The width of the door is the product of the speed of the car and the time.)

3 • **[SSM]** If event A occurs at a different location than event B in some reference frame, might it be possible for there to be a second reference frame in which they occur at the same location? If so, give an example. If not, explain why not.

Determine the Concept Yes. Let the initial frame of reference be frame 1. In frame 1 let L be the distance between the events, let T be the time between the events, and let the $+x$ direction be the direction of event B relative to event A. Next, calculate the value of L/T. If L/T is less than c, then consider the two events in a reference frame 2, a frame moving at speed $v = L/T$ in the $+x$ direction. In frame 2 both events occur at the same location.

4 • [SSM] If event A occurs prior to event B in some frame, might it be possible for there to be a second reference frame in which event B occurs prior to event A? If so, give an example. If not, explain why not.

Determine the Concept Yes. Let L and T be the distance and time between the two events in reference frame 1. If $L \le cT$, then something moving at a speed less than or equal to c could travel from the location of event A to the location of event B in a time less than T. Thus, it is possible that event A could cause event B. For events like these, causality demands that event A must precede event B in all reference frames. However, if $L > cT$ then event A cannot be the cause of event B. For events like these, event B does precede event A in certain reference frames.

5 • [SSM] Two events are simultaneous in a frame in which they also occur at the same location. Are they simultaneous in all other reference frames?

Determine the Concept Yes. If two events occur at the same time *and* place in one reference frame they occur at the same time *and* place in all reference frames. (Any pair of events that occur at the same time *and* at the same place in one reference frame are called a spacetime coincidence.)

6 • Two inertial observers are in relative motion. Under what circumstances can they agree on the simultaneity of two different events?

Determine the Concept We will refer to the two events as event A and event B. Assume that in the reference frame of the first observer there is a stationary clock at the location of each event, with clock A at the location of event A and clock B at the location of event B, and that the two clocks are synchronized. Because the two events are simultaneous in this frame, the readings of the two clocks at the time the events occur are the same. Also, event A and the reading of clock A at the time of event A are a spacetime coincidence, so all observers must agree with that clock reading. In like manner, event B and the reading of clock B at the time of event B are a spacetime coincidence. If observer B is moving parallel with the line joining the two clocks then the clocks readings will differ by Lv/c^2 in the reference frame of B, where L is the distance between the clocks in the reference frame of observer A. This means that observer B will agree that the two clock readings at the times of the events are the same, but will not agree that the events occurred at the same time unless $L = 0$.

7 • The approximate total energy of a particle of mass m moving at speed $v << c$ is (*a*) $mc^2 + \frac{1}{2}mv^2$, (*b*) mv^2, (*c*) cmv, (*d*) $\frac{1}{2}mc^2$, (*e*) cmv.

Picture the Problem We can use the expression for the total relativistic energy of the particle to express its energy in terms of its speed and expand the radical factor binomially to find the correct approximate expression for the total energy when $v << c$.

Express the total relativistic energy of the particle as the sum of its kinetic energy and the rest energy:

$$E = K + mc^2 = \frac{mc^2}{\sqrt{1-\frac{v^2}{c^2}}}$$

$$= mc^2\left(1-\frac{v^2}{c^2}\right)^{-1/2}$$

Expand the radical factor binomially to obtain:

$$E = mc^2\left(1+\tfrac{1}{2}\frac{v^2}{c^2}+...\right) = mc^2 + \tfrac{1}{2}mv^2 + ...$$

$$\approx mc^2 + \tfrac{1}{2}mv^2 \text{ for } v << c.$$

and $\boxed{(a)}$ is correct.

8 • True or false:

(*a*) The speed of light is the same in all reference frames.
(*b*) The proper time interval is the shortest time interval between two events.
(*c*) Absolute motion can be determined by means of length contraction.
(*d*) The light-year is a unit of distance.
(*e*) For two events to form a space-time coincidence they must occur at the same place.
(*f*) If two events are not simultaneous in one frame, they cannot be simultaneous in any other frame.

(*a*) True. This is Einstein's second postulate.

(*b*) True. The time between events that happen at the *same place* in a reference frame is called the proper time and the time interval Δt measured in any other reference frame is always longer than the proper time.

(*c*) False. Absolute motion cannot be detected.

(*d*) True. A light-year is the distance light travels (in a vacuum) in one year.

(*e*) True. For two events to form a space-time coincidence, they must not only occur at the same place but must also occur at the same location.

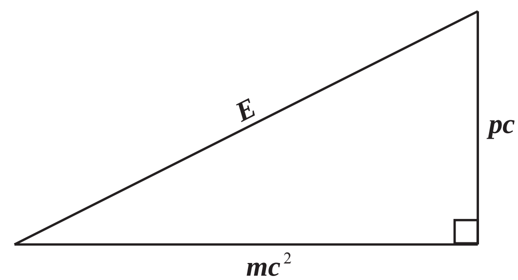
(*f*) False. The fact that two events are not simultaneous in one frame tells us nothing about their simultaneity in any other frame.

9 •• (*a*) Show that *pc* has dimensions of energy. (*b*) There is a geometrical interpretation of Equation R-17 based on the Pythagorean Theorem. Draw a picture of a triangle illustrating this interpretation.

(*a*) Express the dimensions of *pc* and simplify them to obtain:

$$[p][c]=\left(M\cdot\frac{L}{T}\right)\left(\frac{L}{T}\right)=M\cdot\left(\frac{L}{T}\right)^2$$
$$=\frac{ML^2}{T^2}=[E]$$

(*b*) The geometrical interpretation, based on the Pythagorean Theorem, of Equation R-17 is shown to the right:



10 •• A wad of putty of mass m_1 strikes and sticks to a second wad of putty of mass m_2 which is initially at rest. Do you expect that after the collision the combined putty mass will be (*a*) greater than, (*b*) less than, (*c*) the same as $m_1 + m_2$. Explain your answer.

Determine the Concept Because the collision is inelastic, kinetic energy is converted into mass energy. $\boxed{(a)}$ is correct.

11 •• **[SSM]** Many nuclei of atoms are unstable; for example, ^{14}C, an isotope of carbon, has a half-life of 5700 years. (By definition, the *half-life* is the time it takes for any given number of unstable particles to decay to half that number of particles.) This fact is used extensively for archeological and biological dating of old artifacts. Such unstable nuclei decay into several decay products, each with significant kinetic energy. Which of the following is true? (*a*) The mass of the unstable nucleus is larger than the sum of the masses of the decay products. (*b*) The mass of the unstable nucleus is smaller than the sum of the masses of the decay products. (*c*) The mass of the unstable nucleus is the same as the sum of the masses of the decay products. Explain your choice.

Determine the Concept Because mass is converted into the kinetic energy of the fragments, the mass of the unstable nucleus is larger than the sum of the masses of the decay products. $\boxed{(a)}$ is correct.

12 •• Positron emission tomography **(**PET) scans are common in modern medicine. In this procedure, positrons (a positron has the same mass, but the opposite charge as an electron) are emitted by radioactive nuclei that have been introduced into the body. Assume that an emitted positron, traveling slowly (with negligible kinetic energy) collides with an electron traveling at the same slow speed in the opposite direction. They undergo annihilation and two quanta of light (photons) are formed. You are in charge of designing detectors to receive these photons and measure their energy. (*a*) Explain why you would expect these two photons to come off in exactly opposite directions. (*b*) In terms of the electron mass m_e , how much energy would each photon have? (1) less than mc^2, (2) greater than mc^2, (3) exactly mc^2. Explain your choice.

Determine the Concept
(*a*) The linear momentum of the electron-positron pair was zero just before their annihilation and the emission of the two photons and therefore the linear momentum of the two photons must be zero.

(*b*) $\boxed{(3)}$ is correct. Each photon has the rest mass energy, m_ec^2, equivalent of an electron. Because there are two photons and they have the same momentum, they share equally, each getting half the available initial rest energy of $2m_ec^2$.

Estimation and Approximation

13 •• **[SSM]** In 1975, an airplane carrying an atomic clock flew back and forth at low altitude for 15 hours at an average speed of 140 m/s as part of a time-dilation experiment. The time on the clock was compared to the time on an atomic clock kept on the ground. What is the time difference between the atomic clock on the airplane and the atomic clock on the ground? (Ignore any effects that accelerations of the airplane have on the atomic clock which is on the airplane. Also assume that the airplane travels at constant speed.)

Picture the Problem We can use the time dilation equation to relate the elapsed time in the frame of reference of the airborne clock to the elapsed time in the frame of reference of the clock kept on the ground.

Use the time dilation equation to relate the elapsed time Δt according to the clock on the ground to the elapsed time Δt_0 according to the airborne atomic clock:

$$\Delta t = \frac{\Delta t_0}{\sqrt{1-\left(\frac{v}{c}\right)^2}} \qquad (1)$$

Because $v << c$, we can use the approximation $\frac{1}{\sqrt{1-x}} \approx 1+\frac{1}{2}x$ to obtain:

$$\frac{1}{\sqrt{1-\left(\frac{v}{c}\right)^2}} \approx 1+\frac{1}{2}\left(\frac{v}{c}\right)^2$$

Substitute in equation (1) to obtain:

$$\Delta t = \left[1 + \frac{1}{2}\left(\frac{v}{c}\right)^2\right]\Delta t_0 = \Delta t_0 + \frac{1}{2}\left(\frac{v}{c}\right)^2 \Delta t_0 \qquad (2)$$

where the second term represents the additional time measured by the clock on the ground.

Evaluate the proper elapsed time according to the clock on the airplane:

$$\Delta t_0 = (15\,\text{h})\left(3600\,\frac{\text{s}}{\text{h}}\right) = 5.40\times 10^4\ \text{s}$$

Substitute numerical values and evaluate the second term in equation (2):

$$\Delta t' = \frac{1}{2}\left(\frac{140\,\text{m/s}}{2.998\times 10^8\ \text{m/s}}\right)^2 (5.40\times 10^4\ \text{s}) = 5.89\times 10^{-9}\ \text{s} \approx \boxed{5.9\,\text{ns}}$$

14 •• (*a*) By making any necessary assumptions and finding certain stellar distances, estimate the speed at which a spaceship would have to travel for its passengers to make a trip to the nearest star (not the Sun!) and back to Earth in 1.0 Earth years, as measured by an observer on the ship. Assume the passengers make the outgoing and return trips at constant speed and ignore any effects due to the spaceship stopping and starting. (*b*) How much time would elapse on Earth during their roundtrip? Include 2.0 Earth years for a low-speed exploration of the planets in the vicinity of this star.

Picture the Problem We can use the length-contraction equation $L = L_0\sqrt{1-(v/c)^2}$ and $\Delta t = L/v$ to estimate the speed of the spaceship. Note that there is no time dilation effect during the two-year exploration period. Take the distance to the nearest sun to be 4.0 c·y.

(*a*) According to the travelers, the elapsed time for the trip is:

$$\Delta t = \frac{L}{v} = \frac{L_0\sqrt{1-(v/c)^2}}{v}$$

Multiplying both sides of the equation by c yields:

$$c\Delta t = \frac{cL_0\sqrt{1-(v/c)^2}}{v} = \frac{L_0\sqrt{1-(v/c)^2}}{v/c}$$

Because $c\Delta t$ = 1.0 c·y and L_0 = 4.0 c·y:

$$1.0 = \frac{4.0\sqrt{1-(v/c)^2}}{v/c}$$

Solve for v to obtain:

$$v=\sqrt{\frac{16}{17}}c=\boxed{0.97c}$$

(*b*) Express the elapsed time as the sum of the travel and exploration times:

$$\Delta t=\Delta t_{\text{travel}}+\Delta t_{\text{exploration}}=2\Delta t_{1\text{ wayl}}+\Delta t_{\text{exploration}}\qquad(1)$$

In the Earth frame-of reference:

$$\Delta t_{1\text{ way}}=\frac{L_0}{v}=\frac{4.0\,c\cdot\text{y}}{0.97c}=4.12\text{ y}$$

Substitute numerical values in equation (1) and evaluate Δt:

$$\Delta t=2(4.12\text{ y})+2.0\text{ y}=\boxed{10.2\text{ y}}$$

15 •• (*a*) Compare the kinetic energy of a moving car to its rest energy. (*b*) Compare the total energy of a moving car to its rest energy. (*c*) Estimate the error made in computing the kinetic energy of a moving car using non-relativistic expressions compared to the relativistically correct expressions. *Hint: Use of the binomial expansion may help.*

Picture the Problem We can compare these energies by expressing their ratios. Assume that the speed of the car is 30 m/s (≈ 67 mi/h).

(*a*) Express the ratio of the kinetic energy of a moving car to its rest energy:

$$\frac{K}{mc^2}=\frac{\frac{1}{2}mv^2}{mc^2}=\frac{1}{2}\left(\frac{v}{c}\right)^2$$

For a car moving at 30 m/s:

$$\frac{K}{mc^2}=\frac{1}{2}\left(\frac{30\text{ m/s}}{2.998\times10^8\text{ m/s}}\right)^2\approx\boxed{5\times10^{-13}\%}$$

(*b*) Express the ratio of the total energy of a moving car to its rest energy:

$$\frac{E}{mc^2}=\frac{K+mc^2}{mc^2}=\frac{K}{mc^2}+1\approx\boxed{1.000\,000\,000\,000\,005}$$

(*c*) The error made in computing the kinetic energy of a moving car using the non-relativistic expression compared to the relativistically correct expression is given by:

$$\frac{\Delta K}{K_{\text{rel}}}=\left|\frac{K_{\text{non-rel}}-K_{\text{rel}}}{K_{\text{rel}}}\right|=\left|\frac{K_{\text{non-rel}}}{K_{\text{rel}}}-1\right|\qquad(1)$$

From Equation R-14, the relativistic kinetic energy is given by:

$$K_{\text{rel}}=\left[\left(1-\frac{v^2}{c^2}\right)^{-\frac{1}{2}}-1\right]mc^2\qquad(2)$$

Expand $\left(1-\frac{v^2}{c^2}\right)^{-\frac{1}{2}}$ binomially to obtain:

$$\left(1-\frac{v^2}{c^2}\right)^{-\frac{1}{2}} = 1+\frac{1}{2}\frac{v^2}{c^2}+\frac{3}{8}\frac{v^4}{c^4}+\ldots \approx 1+\frac{1}{2}\frac{v^2}{c^2}+\frac{3}{8}\frac{v^4}{c^4}$$

Substituting in equation (2) and simplifying yields:

$$\begin{aligned} K_{\text{rel}} &= \left[\frac{1}{2}\frac{v^2}{c^2}+\frac{3}{8}\frac{v^4}{c^4}\right]mc^2 \\ &= \frac{1}{2}mv^2+\frac{3}{8}mv^2\left(\frac{v^2}{c^2}\right) \\ &= K_{\text{non-rel}}\left(1+\frac{3}{4}\frac{v^2}{c^2}\right) \end{aligned}$$

Substitute for K_{rel} in equation (1) and simplify to obtain:

$$\begin{aligned} \frac{\Delta K}{K_{\text{rel}}} &= \left|\frac{K_{\text{non-rel}}}{K_{\text{non-rel}}\left(1+\frac{3}{4}\frac{v^2}{c^2}\right)}-1\right| \\ &= \left|\left(1+\frac{3}{4}\frac{v^2}{c^2}\right)^{-1}-1\right| \end{aligned}$$

Expanding $\left(1+\frac{3}{4}\frac{v^2}{c^2}\right)^{-1}$ binomially yields:

$$\left(1+\frac{3}{4}\frac{v^2}{c^2}\right)^{-1} = 1+(-1)\left(\frac{3}{4}\frac{v^2}{c^2}\right)+\frac{(-1)(-2)}{2}\left(\frac{3}{4}\frac{v^2}{c^2}\right)^2+\ldots \approx 1-\left(\frac{3}{4}\frac{v^2}{c^2}\right)$$

Substitute for $\left(1+\frac{3}{4}\frac{v^2}{c^2}\right)^{-1}$ in the expression for $\frac{\Delta K}{K_{\text{rel}}}$ to obtain:

$$\frac{\Delta K}{K_{\text{rel}}} = \left|\left(1-\frac{3}{4}\frac{v^2}{c^2}\right)-1\right| = \frac{3}{4}\frac{v^2}{c^2}$$

Substitute numerical values and evaluate $\frac{\Delta K}{K_{\text{rel}}}$:

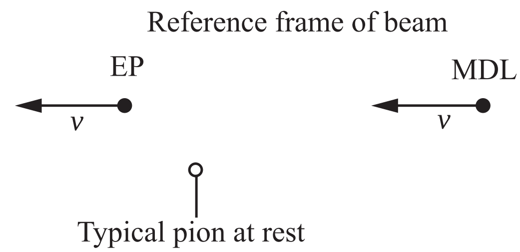
$$\frac{\Delta K}{K_{\text{rel}}} = \frac{3}{4}\frac{(30\text{ m/s})^2}{(2.998\times10^8\text{ m/s})^2} = \boxed{7.5\times10^{-15}}$$

Length Contraction and Time Dilation

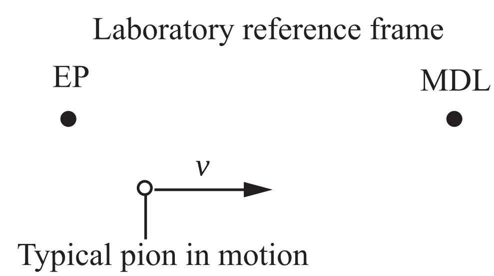
16 • The proper average (or mean) lifetime of a pion (a subatomic particle) is 2.6×10^{-8} s. (A neutral pion has a much shorter lifetime. See Chapter 41.) A beam of pions has a speed of $0.85c$ relative to a laboratory. (*a*) What would be their mean lifetime as measured in that laboratory? (*b*) On average, how far would they travel in that laboratory before they decay? (*c*) What would be your answer to Part (*b*) if you had neglected time dilation?

Picture the Problem The pion beam enters the laboratory at a point called the entrance port (EP). A typical pion in the beam disintegrates at a second point called the mean disintegration location (MDL). Event A occurs when a typical pion enters the room at EP, and event B occurs when the pion disintegrates at MDL. (*a*) In the reference frame of the beam these two events occur at the same location, so the time Δt_0 between these two events in this frame is the proper time between the events. We can use the time dilation formula to calculate the time Δt between these events in the reference frame of the laboratory, a reference frame that moves with speed $v = 0.85c$ relative to the reference frame of the beam.
(*b*) In the reference frame of the room a typical pion travels at speed v for time Δt.

(*a*) Sketch a typical pion in the reference frame of the pion beam. In this frame the typical pion is at rest and both EP and MDL are moving at speed v. Event A occurs when EP is next to a typical pion, and event B occurs when MDL reaches the pion at the instant the pion disintegrates:



Sketch a typical pion in the reference frame of the laboratory. In this frame the typical pion moves at speed v. Event A occurs when a typical pion enters the room at EP, and event B occurs when the pion reaches MDL at the instant the pion disintegrates:



Use the time-dilation equation to relate the mean lifetime Δt of a typical pion in the laboratory frame to the proper mean lifetime Δt_0 in the reference frame of the beam:

$$\Delta t = \frac{\Delta t_0}{\sqrt{1-\left(\frac{v}{c}\right)^2}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2.6\times10^{-8}\ \text{s}}{\sqrt{1-\left(\frac{0.85c}{c}\right)^2}} = 4.94\times10^{-8}\ \text{s}$$
$$= \boxed{4.9\times10^{-8}\ \text{s}}$$

(*b*) Express the distance a typical pion will travel in the lab frame before it decays in terms of its speed and its mean lifetime in the lab frame:

$$\Delta x = v\Delta t$$

Substitute numerical values and evaluate Δx:

$$\Delta \boldsymbol{x} = (0.85\boldsymbol{c})(4.94\times10^{-8}\ \text{s}) = \boxed{13\ \text{m}}$$

(*c*) Neglecting time dilation, $\Delta t = 2.6 \times 10^{-8}$ s, and:

$$\Delta \boldsymbol{x} = (0.85\boldsymbol{c})(2.6\times10^{-8}\ \text{s}) = \boxed{6.6\ \text{m}}$$

17 • **[SSM]** In the reference frame of a pion in Problem 16, how far does the laboratory travel in 2.6×10^{-8} s?

Picture the Problem We can use $\Delta x = v\Delta t_\pi$, where Δt_π is the proper mean lifetime of the pions, to find the distance traveled by the laboratory frame in a typical pion lifetime.

The average distance the laboratory will travel before the pions decay is the product of the speed of the pions and their proper mean lifetime:

$$\Delta x = v\Delta t_\pi$$

Substitute numerical values and evaluate Δx:

$$\Delta x = (0.85c)(2.6\times10^{-8}\ \text{s}) = 6.63\ \text{m}$$
$$= \boxed{6.6\ \text{m}}$$

18 • The proper average (or mean) lifetime of a muon (a subnuclear particle) particle is 2.20 μs. Muons in a beam are traveling at 0.999c relative to a laboratory. (*a*) What is their lifetime as measured in that laboratory? (*b*) On average, how far do they travel in that laboratory before they decay?

Picture the Problem We can express the mean lifetimes of the muons in the laboratory in terms of their proper lifetimes using $\Delta t = \Delta t_0 \big/ \sqrt{1-(v/c)^2}$. The average distance the muons will travel before they decay is related to their speed and mean lifetime in the laboratory frame according to $\Delta x = v\Delta t$.

(*a*) Use the time-dilation equation to relate the mean lifetime of a muon in the laboratory Δt to their proper mean lifetime Δt_0:

$$\Delta t = \frac{\Delta t_0}{\sqrt{1-\left(\frac{v}{c}\right)^2}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2.20\times10^{-6}\ \text{s}}{\sqrt{1-\left(\frac{0.999c}{c}\right)^2}} = 49.2\ \mu\text{s}$$

$$= \boxed{49\ \mu\text{s}}$$

(*b*) The average distance muons travel before they decay in terms of their speed and mean lifetime in the laboratory frame of reference is:

$$\Delta x = v\Delta t$$

Substitute numerical values and evaluate Δx:

$$\Delta x = (0.999c)(49.2\ \mu\text{s}) = \boxed{15\,\text{km}}$$

19 • In the reference frame of the muon in Problem 20, how far does the laboratory travel in 2.20 μs?

Picture the Problem We can use $\Delta x = v\Delta t_\pi$, where Δt_π is the proper mean lifetime of the pions, to find the distance traveled by the laboratory frame in a typical pion lifetime and $\Delta x_0 = \Delta x \big/ \sqrt{1-(v/c)^2}$ to find this distance in the laboratory's frame.

Express the average distance the laboratory will travel before the pions decay in terms of the speed of the pions and their proper mean lifetime:

$$\Delta x = v\Delta t_\pi$$

Substitute numerical values and evaluate Δx:

$$\Delta x = (0.999c)(2.20\ \mu\text{s}) = \boxed{659\,\text{m}}$$

20 • You have been posted in a remote region of space to monitor traffic. Toward the end of a quiet shift, a spacecraft goes by and you measure its length using a laser device. This device reports a length of 85.0 m. You flip open your handy reference catalogue and identify the craft as a CCCNX-22, which has a proper length of 100 m. When you phone in your report, what speed should you give for this spacecraft?

Picture the Problem The measured length L of the spacecraft is related to its proper length L_0 and its speed according to $L = L_0\sqrt{1-\left(v^2/c^2\right)}$. We can solve this equation for v as a function of c, L, and L_0.

Express the length L of the spacecraft in terms of its proper length L_0:

$$L = L_0\sqrt{1-\frac{v^2}{c^2}} \Rightarrow v = c\sqrt{1-\left(\frac{L}{L_0}\right)^2}$$

Substitute numerical values and evaluate v:

$$v = \left(2.998\times10^8\ \text{m/s}\right)\sqrt{1-\left(\frac{85.0\,\text{m}}{100\,\text{m}}\right)^2}$$

$$= \boxed{1.58\times10^8\ \text{m/s}}$$

21 • **[SSM]** A spaceship travels from Earth to a star 95 light-years away at a speed of 2.2×10^8 m/s. How long does the spaceship take to get to the star (*a*) as measured on Earth and (*b*) as measured by a passenger on the spaceship?

Picture the Problem We can use $\Delta x = v\Delta t$ to find the time for the trip as measured on Earth and $\Delta t_0 = \Delta t\sqrt{1-\left(v/c\right)^2}$ to find the time measured by a passenger on the spaceship.

(*a*) Express the elapsed time, as measured on Earth, in terms of the distance traveled and the speed of the spaceship:

$$\Delta t = \frac{\Delta x}{v}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{95\,c\cdot\text{y}}{2.2\times10^8\ \text{m/s}}\times\frac{9.461\times10^{15}\ \text{m}}{c\cdot\text{y}}$$

$$= 4.09\times10^9\ \text{s}\times\frac{1\,\text{y}}{31.56\,\text{Ms}} = 129\,\text{y}$$

$$= \boxed{1.3\times10^2\ \text{y}}$$

(*b*) A passenger on the spaceship will measure the proper time:

$$\Delta t_0 = \Delta t\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate the proper time:

$$\Delta t_0 = (129\,\text{y})\sqrt{1-\frac{(2.2\times10^8\ \text{m/s})^2}{(2.998\times10^8\ \text{m/s})^2}} = \boxed{88\,\text{y}}$$

22 • The average lifetime of a beam of subatomic particles called pions (see Problem 16 for details on these particles) traveling at high speed is measured to be 7.5 × 10^{-8} s. Their average lifetime at rest is known to be 2.6 × 10^{-8} s. How fast is this pion beam traveling?

Picture the Problem We can express the mean lifetime of the pion in the laboratory in terms of its proper lifetime using $\Delta t = \Delta t_0 \big/ \sqrt{1-(v/c)^2}$ and solve for v to find its speed.

Use the time-dilation equation to relate the mean lifetime of a muon in the laboratory Δt to their proper mean lifetime Δt_0:

$$\Delta t = \frac{\Delta t_0}{\sqrt{1-\frac{v^2}{c^2}}} \Rightarrow v = c\sqrt{1-\left(\frac{\Delta t_0}{\Delta t}\right)^2}$$

Substitute numerical values and evaluate v:

$$v = (2.998\times10^8\ \text{m/s})\sqrt{1-\left(\frac{2.6\times10^{-8}\ \text{s}}{7.5\times10^{-8}\ \text{s}}\right)^2} = \boxed{2.8\times10^8\ \text{m/s}}$$

23 • A meterstick moves with speed 0.80*c* relative to you in the direction parallel to the stick. (*a*) Find the length of the stick as measured by you. (*b*) How long does it take for the stick to pass you?

Picture the Problem We can find the measured length L of the meterstick using $L = L_0\sqrt{1-(v^2/c^2)}$ and the time it takes to pass you using $L = v\Delta t$.

(*a*) Express the length L of the meterstick in terms of its proper length L_0:

$$L = L_0\sqrt{1-\frac{v^2}{c^2}}$$

Substitute numerical values and evaluate L:

$$L = (1.0\,\text{m})\sqrt{1-\frac{(0.8c)^2}{c^2}} = \boxed{60\,\text{cm}}$$

(*b*) Express the time it takes for the meterstick to pass you in terms of its apparent length and speed:

$$\Delta t = \frac{L}{v}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{0.60\,\text{m}}{0.8c} = \boxed{2.5\,\text{ns}}$$

24 • Recall that the half-life is the time it takes for any given amount of unstable particles to decay to half that amount of particles. The proper half-life of a species of charged subatomic particles called pions is 1.80×10^{-8} s (See Problem 16 for details on pions.) . Suppose a group of these pions are produced in an accelerator and emerge with a speed of 0.998*c*. How far do these particles travel in the accelerator's laboratory before half of them have decayed?

Picture the Problem We can express the distance the pions will travel in the laboratory using $\Delta x = v\Delta t$ and find their half-life in the accelerator laboratory using $\Delta t = \Delta t_0 \big/ \sqrt{1-(v/c)^2}$.

Express the average distance the pions will travel before decaying in terms of their speed proper mean lifetime:

$$\Delta x = v\Delta t$$

Use the time-dilation equation to relate the mean lifetimes of the pions in the accelerator laboratory Δt to their proper mean lifetime Δt_0:

$$\Delta t = \frac{\Delta t_0}{\sqrt{1-\left(\frac{v}{c}\right)^2}}$$

Substitute for Δt to obtain:

$$\Delta x = \frac{v\Delta t_0}{\sqrt{1-\left(\frac{v}{c}\right)^2}}$$

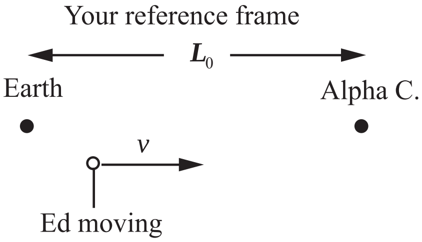
Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{(0.998c)(1.80\times10^{-8}\,\text{s})}{\sqrt{1-\left(\frac{0.998c}{c}\right)^2}} = \boxed{85.2\,\text{m}}$$

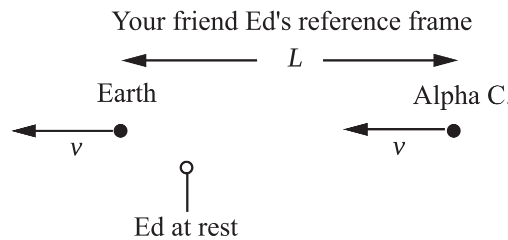
25 •• [SSM] Your friend, who is the same age as you, travels to the star Alpha Centauri, which is 4.0 light-years away, and returns immediately. He claims that the entire trip took just 6.0 y. What was his speed? Ignore any accelerations of your friend's spaceship and assume the spaceship traveled at the same speed during the entire trip.

Picture the Problem To calculate the speed in the reference frame of the friend, who is named Ed, we consider each leg of the trip separately. Consider an imaginary stick extending from Earth to Alpha Centauri that is at rest relative to Earth. In Ed's frame the length of the stick, and thus the distance between Earth and Alpha Centauri, is shortened in accord with the length contraction formula. As three years pass on Ed's watch Alpha Centauri travels at speed v from its initial location to him.

Sketch the situation as it is in your reference frame. The distance between Earth and Alpha C. is the rest length L_0 of the stick discussed in Picture the Problem:



Sketch the situation as it is in Ed's reference frame. The distance between Earth and Alpha C. is the length L of the moving stick discussed in Picture the Problem:



The two events are Ed leaves Earth and Ed arrive at Alpha Centauri. In Ed's frame these two events occur at the same place (next to Ed). Thus, the time between those two events Δt_0 is the proper time between the two events.

$$\Delta t_0 = 3\text{ y}$$

The distance L traveled by Alpha Centauri in Ed's frame during the first three years equals the speed multiplied by the time in Ed's frame:

$$L = v\Delta t_0$$

The distance between Earth and Alpha Centauri in Ed's frame is the contracted length of the imaginary stick:

$$L = L_0\sqrt{1-\frac{v^2}{c^2}}$$

Equate these expressions for L to obtain:

$$L_0\sqrt{1-\frac{v^2}{c^2}} = v\Delta t_0$$

Substituting numerical values yields:

$$(4.0\,c\cdot\text{y})\sqrt{1-\frac{v^2}{c^2}}=v(3.0\text{ y})$$

or

$$1-\frac{v^2}{c^2}=\frac{9}{16}\frac{v^2}{c^2}\Rightarrow\frac{25}{16}\left(\frac{v^2}{c^2}\right)=1$$

Solving for v gives:

$$v=\boxed{0.80c}$$

26 •• Two spaceships pass each other traveling in opposite directions. A passenger in ship A knows that her ship is 100 m long. She notes that ship B is moving with a speed of 0.92c relative to A and that the length of B is 36 m. What are the lengths of the two spaceships as measured by a passenger in ship B?

Picture the Problem We can use the relationship between the measured length L of the spaceships and their proper lengths L_0 to find the lengths of the two spaceships as measured by a passenger in ship B.

Relate the measured length L_A of ship A to its proper length:

$$L_A=L_{0,A}\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate L_A:

$$L_A=(100\text{ m})\sqrt{1-\left(\frac{0.92c}{c}\right)^2}=\boxed{39\text{ m}}$$

Relate the proper length $L_{0,B}$ of ship B to its measured length L_B:

$$L_{0,B}=\frac{L_B}{\sqrt{1-\left(\frac{v}{c}\right)^2}}$$

Substitute numerical values and evaluate $L_{0,B}$:

$$L_{0,B}=\frac{36\text{ m}}{\sqrt{1-\left(\frac{0.92c}{c}\right)^2}}=\boxed{92\text{ m}}$$

27 •• Supersonic jets achieve maximum speeds of about $3.00\times10^{-6}c$. (*a*) By what percentage would a jet traveling at this speed contract in length? (*b*) During a time of exactly one year or 3.15×10^{7} s on your clock, how much time would elapse on the pilot's clock? How much time is lost by the pilot's clock in one year of your time? Assume you are on the ground and the pilot is flying at the specified speed for the entire year.

Picture the Problem We can use the relationship between the measured length L of the jet and its proper length to express the fractional change in the length of the jet traveling at its maximum speed. In Part (*b*) we can express the elapsed time on the pilot's clock Δt_0 in terms of the elapsed time Δt on your clock.

(*a*) Express the fractional change in length of the jet:

$$\frac{L_0 - L}{L_0} = 1 - \frac{L}{L_0}$$

Relate L to L_0:

$$L = L_0\sqrt{1-\left(\frac{v}{c}\right)^2} \Rightarrow \frac{L}{L_0} = \sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute for L/L_0 to obtain:

$$\frac{L_0 - L}{L_0} = 1 - \sqrt{1-\frac{v^2}{c^2}} \qquad (1)$$

Expand $\sqrt{1-\frac{v^2}{c^2}}$ binomially to obtain:

$$\left(1-\frac{v^2}{c^2}\right)^{\frac{1}{2}} = 1 - \frac{1}{2}\frac{v^2}{c^2} + \frac{3}{8}\frac{v^4}{c^4} + \ldots$$

$$\approx 1 - \frac{1}{2}\frac{v^2}{c^2}$$

Substituting in equation (1) yields:

$$\frac{L_0 - L}{L_0} = 1 - \left(1 - \frac{1}{2}\frac{v^2}{c^2}\right) = \frac{1}{2}\frac{v^2}{c^2}$$

Substitute numerical values and evaluate the jet's fractional change in length:

$$\frac{L_0 - L}{L_0} \approx \frac{1}{2}\frac{\left(3.00\times10^{-6}c\right)^2}{c^2}$$

$$= \boxed{4.50\times10^{-10}\%}$$

(*b*) Express the elapsed time on the pilot's clock Δt_0 in terms of the elapsed time Δt on your clock:

$$\Delta t_0 = \left(1-\frac{v^2}{c^2}\right)^{\frac{1}{2}}\Delta t \approx \Delta t\left(1 - \frac{1}{2}\frac{v^2}{c^2}\right)$$

$$= \Delta t - \frac{1}{2}\frac{v^2}{c^2}\Delta t$$

where the second term represents the time lost on the pilot's clock.

Substitute numerical values and evaluate the elapsed time on the pilot's clock in 1 y = 3.15 × 10^7 s:

$$\Delta t_0 = \left(1-\frac{1}{2}\frac{v^2}{c^2}\right)\Delta t = \left(1-\frac{1}{2}\frac{\left(3.00\times10^{-6}\,c\right)^2}{c^2}\right)\left(3.15\times10^{7}\text{ s}\right) = \boxed{1.00\text{ y}}$$

The time lost by the pilot's clock in time Δt of your time is given by:

$$\Delta t - \Delta t_0 = \frac{1}{2}\frac{v^2}{c^2}\Delta t$$

Substitute numerical values and evaluate $\Delta t - \Delta t_0$ for 1 y = 3.15 × 10^7 s:

$$\Delta t - \Delta t_0 = \frac{1}{2}\frac{\left(3.00\times10^{-6}\,c\right)^2}{c^2}\left(3.15\times10^{7}\text{ s}\right) = \left(142\ \mu\text{s}\right)\left(\frac{1\text{ min}}{60\text{ s}}\right) = \boxed{2.37\ \mu\text{min}}$$

28 •• The proper mean lifetime of a muon (see Problems 18 and 19 for details) is 2.20 μs. Consider a muon, created in Earth's atmosphere, speeding toward the surface 8.00 km below, at a speed of 0.980c. (*a*) What is the likelihood that it will survive its trip to ground before decaying? The probability of a muon decaying is given by $P = 1 - e^{-\Delta t/\tau}$, where Δt is the time interval as measured in the reference frame in question. (*b*) Calculate this from the point of view of an observer moving with the muon. Show that, from the point of view of an observer on Earth, the answer is the same.

Picture the Problem We can use the given probability function to find the probability of the muon's survival from both the point of view of an Earth observer and the muon. To do so, we'll need to use the time-dilation relationship in (*a*) and the length-contraction relationship in (*b*).

(*a*) The probability of a muon decaying is $P = 1 - e^{-\Delta t/\tau}$, so the probability of survival is:

$$P_{\text{survival}} = e^{-\Delta t/\tau} \qquad (1)$$

From the point of view of an observer on Earth:

$$\Delta t = \frac{L}{v} = \frac{8000\text{ m}}{(0.980)\left(2.998\times10^{8}\text{ m/s}\right)} = 27.229\ \mu\text{s}$$

The mean lifetime of the muon is given by:

$$\tau = \frac{\tau_0}{\sqrt{1-\left(\frac{v}{c}\right)^2}} = \frac{2.20\ \mu\text{s}}{\sqrt{1-(0.980)^2}} = 11.055\ \mu\text{s}$$

Substitute numerical values in equation (1) and evaluate P_{survival}:

$$P = e^{-\frac{27.229\ \mu\text{s}}{11.055\ \mu\text{s}}} = \boxed{8.5\%}$$

(*b*) From the point of view of the muon:

$$\Delta t = \frac{L}{v} \qquad (2)$$

The muon's reference frame is the one in which it is at rest and Earth is rushing toward it at 0.980*c*. Express the thickness of Earth's atmosphere as measured in the muon's frame of reference:

$$L = L_0\sqrt{1 - v^2/c^2}$$

Substituting for L in equation (2) yields:

$$\Delta t = \frac{L_0\sqrt{1 - v^2/c^2}}{v}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{8000\ \text{m}\sqrt{1 - (0.980)^2}}{(0.980)(2.998\times10^8\ \text{m/s})} = 5.419\ \mu\text{s}$$

Substituting numerical values in equation (1) yields:

$$P_{\text{survival}} = e^{-\frac{5.419\ \mu\text{s}}{2.20\ \mu\text{s}}} = \boxed{8.5\%}$$

a result that agrees, to two significant figures, with the result obtained in (*a*).

29 •• A spaceship commander traveling to the Magellanic Clouds, travels at a uniform speed of 0.800c. When leaving the Kuiper belt, whose outer edge is 50.0 AU from Earth (*Note*: 1 AU = 150,000,000 km, and represents the average distance between Earth and the Sun; AU = astronomical unit), he sends a message to ground control, Houston, Texas, saying that he is fine. Fifteen minutes later (according to him) he realizes he has made a typo, so he sends a correction. How much time passes at Houston between the receipt of his initial message and the second message?

Picture the Problem Let ΔT be the proper time interval between event A, the sending of the first message, and event B, the sending of the correction. These two events take place on the ship, so the time interval between the two events it the time interval in the reference frame of the ship. Thus, ΔT = 15 min. Let $\Delta T'$ be the time interval between these same two events in the reference frame of Houston. Then the time between the arrival of the two messages in Houston is $\Delta T_{\substack{\text{between}\\\text{messages}}} = \Delta T' + \Delta T'_{\text{travel}}$.

The time between the arrival of the two messages in Houston is:

$$\Delta T_{\substack{\text{between}\\\text{messages}}} = \Delta T' + \Delta T'_{\text{travel}}$$

Because Houston is moving at speed $v = 0.800c$ relative to the ship:

$$\Delta T' = \frac{\Delta T_{\text{spaceship}}}{\sqrt{1-\left(v^2/c^2\right)}}$$

Substituting for $\Delta T'$ gives:

$$\Delta T_{\substack{\text{between}\\ \text{messages}}} = \frac{\Delta T_{\text{spaceship}}}{\sqrt{1-\left(v^2/c^2\right)}} + \Delta T'_{\text{travel}} \quad (1)$$

During the time interval $\Delta T'$ the ship travels a distance:

$$\Delta x = v\Delta T'$$

The reply has to travel the distance Δx farther than the first message and this takes time $\Delta T'_{\text{travel}}$. The reply travels at speed c, so:

$$\Delta x = c\Delta T'_{\text{travel}}$$

Equating these expressions for Δx gives:

$$v\Delta T' = c\Delta T'_{\text{travel}} \Rightarrow \Delta T'_{\text{travel}} = \frac{v}{c}\Delta T'$$

Substituting for $\Delta T'$ yields:

$$\Delta T'_{\text{travel}} = \frac{v}{c}\frac{\Delta T_{\text{spaceship}}}{\sqrt{1-\left(v^2/c^2\right)}}$$

Substitute for $\Delta T'_{\text{travel}}$ and simplify to obtain:

$$\begin{aligned}\Delta T_{\substack{\text{between}\\ \text{messages}}} &= \frac{\Delta T_{\text{spaceship}}}{\sqrt{1-\left(v^2/c^2\right)}} + \frac{v}{c}\frac{\Delta T_{\text{spaceship}}}{\sqrt{1-\left(v^2/c^2\right)}}\\ &= \frac{\Delta T_{\text{spaceship}}}{\sqrt{1-\left(v^2/c^2\right)}}\left(1+\frac{v}{c}\right)\end{aligned}$$

Substitute numerical values and evaluate $\Delta T_{\substack{\text{between}\\ \text{messages}}}$:

$$\begin{aligned}\Delta T_{\substack{\text{between}\\ \text{messages}}} &= \frac{15\text{ min}}{\sqrt{1-(0.800)^2}}(1+0.800)\\ &= \boxed{45\text{ min}}\end{aligned}$$

The Relativity of Simultaneity

30 • According to Jamal: (*a*) what is the distance between the flashbulb and clock A? (*b*) How far does the flash travel to reach clock A? (*c*) How far does clock A travel while the flash is traveling from the flashbulb to it?

Picture the Problem The proper distance L_0 between the flashbulb and clock A is 50.0 c·min and is related to the distance L measured by Jamal according to $L = L_0\sqrt{1-(v/c)^2}$. Because clock A and the flashbulb are at rest relative to each other, we can find the distance between them using the same relationship with $L_0 = 50.0\ c$·min.

(*a*) Express L in terms of L_0:

$$L = L_0\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate L:

$$L = (50.0\,c\cdot\text{min})\sqrt{1-\left(\frac{0.600c}{c}\right)^2}$$
$$= \boxed{40.0\,c\cdot\text{min}}$$

(*b*) Jamal sees the flash traveling away from him at 1.0*c* and clock A approaching at 0.6*c*. So:

$$\Delta t = \frac{40.0\,c\cdot\text{min}}{1.600c} = 25.0\,\text{min}$$

and so

$$L = \boxed{25.0\,c\cdot\text{min}}$$

(*c*) Express the distance d clock A travels while the flash is traveling to it in terms of the speed of clock A and the time Δt it takes the flash to reach it:

$$d = v\Delta t = v\left(\frac{L}{c}\right)$$

Substitute numerical values and evaluate L:

$$d = (0.600c)\left(\frac{25.0\,c\cdot\text{min}}{c}\right)$$
$$= \boxed{15.0\,c\cdot\text{min}}$$

31 •• According to Jamal, how long does it take the flash to travel to clock A, and what does clock C read as the flash reaches clock A?

Picture the Problem As the light pulse from the flashbulb travels toward clock A with speed *c*, clock A travels toward clock C with speed 0.600*c*. The sum of the distances traveled by the flash and clock *A* must equal the distance separating them as seen in Jamal's frame of reference.

Express the sum of the distances between clock A and the flashbulb as seen in Jamal's frame of reference:

$$0.600ct + ct = \tfrac{1}{2}\ell \Rightarrow t = \frac{\ell}{3.200c}$$

where ℓ is the distance separating clocks A and B.

Express ℓ in terms of ℓ_0:

$$\ell = \ell_0\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute for ℓ to obtain:

$$t=\frac{\ell_0}{3.200c}\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate t:

$$t=\frac{100c\cdot\text{min}}{3.200\text{c}}\sqrt{1-\left(\frac{0.600c}{c}\right)^2}=\boxed{25\,\text{min}}$$

Because clock C starts from zero when the flashbulb passes next to it, its reading when the flash reaches clock A will equal the time required for the flash to travel to clock A. Hence clock C will read:

$$t_C=\boxed{25\,\text{min}}$$

32 •• Show that clock C reads 100 min as the light flash reaches clock B, which is traveling away from clock C with speed 0.600*c*.

Picture the Problem As the light flash from the flashbulb travels toward clock B with speed *c*, clock B travels away from clock C with speed 0.600*c*. The difference between these distances must equal the distance between clock B and the flashbulb as seen in Jamal's frame of reference.

Express the difference between the distances traveled by the flash of light and clock B as seen in Jamal's frame of reference:

$$ct-0.600ct=\tfrac{1}{2}L\Rightarrow t=\frac{L}{0.800c}$$

where L is the separation of clocks A and B.

Use the length contraction equation to express L in terms of L_0:

$$L=L_0\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute for L to obtain:

$$t=\frac{L_0}{0.800c}\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate t:

$$t=\frac{100c\cdot\text{min}}{0.800c}\sqrt{1-\left(\frac{0.600c}{c}\right)^2}=\boxed{100\,\text{min}}$$

33 •• According to Jamal, the reading on clock C advances from 25 min to 100 min between the reception of the flashes by clocks A and B in Problems 31 and 32. According to Jamal, how much will the reading on clock A advance during this 75-min interval?

Picture the Problem We can find the elapsed time on the clock at A (the proper time) from the elapsed time on the clock at B using $\Delta t_0 = \Delta t\sqrt{1-(v/c)^2}$.

Express the elapsed proper time Δt_0 on clock A in terms of the elapsed time Δt measured by Jamal:

$$\Delta t_0 = \Delta t\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate Δt_0:

$$\Delta t_0 = (75\,\text{min})\sqrt{1-\left(\frac{0.600c}{c}\right)^2} = \boxed{60\,\text{min}}$$

34 •• The advance of clock A calculated in Problem 33 is the amount that clock A leads clock B according to Jamal. Compare this result with vL_0/c^2, where $v = 0.600c$.

Picture the Problem We can compare the time calculated in Problem 33 with L_0v/c^2 by evaluating their ratio.

Express the ratio r of L_0v/c^2 to Δt_0:

$$r = \frac{\frac{L_0 v}{c^2}}{\Delta t_0} = \frac{\frac{L_0 v}{c^2}}{\Delta t\sqrt{1-\left(\frac{v}{c}\right)^2}} = \frac{L_0 v}{c^2 \Delta t\sqrt{1-\left(\frac{v}{c}\right)^2}}$$

Substitute numerical values and evaluate r:

$$r = \frac{(100\,c\cdot\text{min})(0.600c)}{c^2(75\,\text{min})\sqrt{1-\left(\frac{0.600c}{c}\right)^2}} = \boxed{1}$$

35 •• **[SSM]** In an inertial reference frame S, event B occurs 2.00 μs after event A and 1.50 km distant from event A. How fast must an observer be moving along the line joining the two events so that the two events occur simultaneously?

For an observer traveling fast enough is it possible for event B to precede event A?

Picture the Problem Because event A is ahead of event B by $L_p v/c^2$ where v is the speed of the observer moving along the line joining the two events, we can use this expression and the given time between the events to find v.

Express the time Δt between events A and B in terms of L_p, v, and c:

$$\Delta t = \frac{L_p v}{c^2} \Rightarrow v = \frac{c^2 \Delta t}{L_p}$$

Substitute numerical values and evaluate v:

$$v = \frac{\left(2.998\times10^8\ \text{m/s}\right)^2 (2.00\ \mu\text{s})}{1.50\ \text{km}}$$

$$= \left(1.20\times10^8\ \text{m/s}\right)\left(\frac{c}{2.998\times10^8\ \text{m/s}}\right)$$

$$= \boxed{0.400c}$$

Rewrite the expression for v in terms of t_A and t_B yields:

$$v = \frac{c^2 (t_B - t_A)}{L_p}$$

Express the condition on $t_B - t_A$ if event B is to precede event A:

$$t_B - t_A < 0 \text{ and } v > \frac{c^2 (t_B - t_A)}{L_p}$$

Substitute numerical values and evaluate v:

$$v > \frac{\left(2.998\times10^8\ \text{m/s}\right)^2 (2.00\ \mu\text{s})}{1.50\ \text{km}}$$

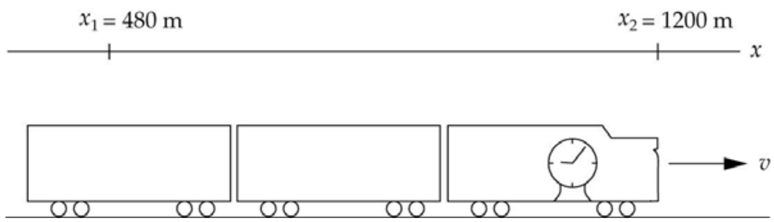
$$= 1.20\times10^8\ \text{m/s} = 0.400c$$

Event B can precede event A provided $v > 0.400c$.

36 •• A large flat space platform has an x axis painted on it. A firecracker explodes on the x axis at $x_1 = 480$ m, and a second firecracker explodes on the x axis 5.00 μs later at $x_2 = 1200$ m. In the reference frame of a train traveling alongside the x axis at speed v relative to the platform, these two explosions occur at the same place on that axis. What is the separation in time between the two explosions in the reference frame of the train?

Picture the Problem Let both explosions occur at the front end of the train—where there is a clock fastened to the train. In the reference frame of the train, both explosions occur at the same place. The clock is stationary in this frame, so it does not run slow. Thus, in this frame the amount the clock reading advances is also the time T_0 between the two events. In the reference frame of the platform the clock (and the train) moves with speed $v = L/T$, where $L = x_2 - x_1$ and

$T = 5.00\ \mu\text{s}$. In this frame the clock is moving so it runs slow, advancing by only $T\sqrt{1-\left(v^2/c^2\right)}$ during time T. All observers must agree with both the clock reading when the first explosion occurs (a spacetime coincidence), and with the clock reading when the second firecracker goes off (also a spacetime coincidence). Thus, all observers agree with the amount the clock reading changes by in the interval between the two events.



Equate the expressions for the amount the clock advances to obtain:

$$T_0 = T\sqrt{1-\left(v^2/c^2\right)}$$

Substitute L/T for v to obtain:

$$T_0 = T\sqrt{1-\left(\frac{L}{cT}\right)^2}$$

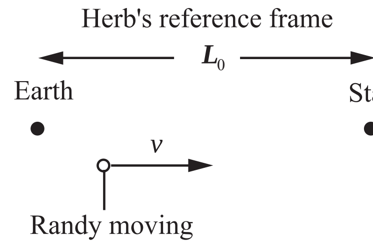
Substitute numerical values and evaluate T_0:

$$T_0 = (5.00\ \mu\text{s})\sqrt{1-\left(\frac{1200\,\text{m}-480\,\text{m}}{\left(2.998\times10^8\ \text{m/s}\right)\left(5.00\times10^{-6}\ \text{s}\right)}\right)^2} = \boxed{4.39\ \mu\text{s}}$$

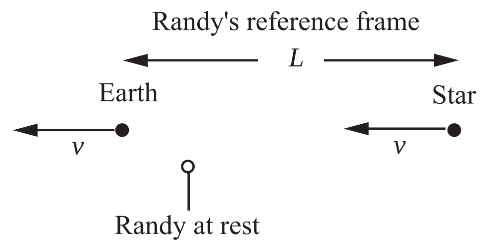
37 •• Herb and Randy are twin jazz musicians who perform as a trombone–saxophone duo. At the age of twenty, however, Randy got an irresistible offer to perform on a star 15 light-years away. To celebrate his good fortune, he bought a new vehicle for the trip—a deluxe space-coupe that travels at 0.99*c*. Each of the twins promises to practice diligently, so they can reunite afterward. However, Randy's gig goes so well that he stays for a full 10 years before returning to Herb. After their reunion, (*a*) how many years of practice will Randy have had; (*b*) how many years of practice will Herb have had?

Picture the Problem Randy's clocks, including his biological clocks, are always at rest in Randy's reference frame, so they advance at the same rate that time advances in Randy's frame. The same is true for Herb and the clocks in his reference frame. Think of a long imaginary stick, at rest relative to Earth, with one end at Earth and the other at the star. The rest length of this stick is 15 c·y. The time Randy has to practice is the time for the trip in Randy's reference frame, and the time Herb has to practice is the time for Randy's trip in Herb's reference frame.

Sketch the situation as it is in Herb's reference frame. The distance between Earth and the star is the rest length L_0 of the stick (discussed in **Picture the Problem**):



Sketch the situation as it is in Randy's reference frame. The distance between Earth and the star is the length L of the moving stick (discussed in Picture the Problem):



To find the time T_0 in Randy's reference frame for the star to travel the distance L we apply the formula distance equals speed multiplied by time. However, to do this we must find L, which is related to L_0 by the length contraction formula:

$$L = vT_0 \Rightarrow T_0 = \frac{L}{v} = \frac{L_0\sqrt{1-\dfrac{v^2}{c^2}}}{v}$$

Substitute numerical values and evaluate T_0:

$$T_0 = \frac{15c\cdot\text{y}\sqrt{1-(0.99)^2}}{0.99c} = 2.137\ \text{y}$$

To find the time T in Herb's reference frame for Randy to travel to the star we apply the formula distance equals speed multiplied by the time:

$$L_0 = vT \Rightarrow T = \frac{L_0}{v}$$

Substitute numerical values and evaluate T:

$$T = \frac{15c\cdot\text{y}}{0.99c} = 15.152\ \text{y}$$

While Randy is at the Star the two reference frames are at rest relative to each other. Thus, the time that Randy is at the star is the same in both frames. The calculations for the return trip give the same result as for the outgoing trip.

(*a*) The time for the trip in Randy's frame is $10\ \text{y} + 2(2.137\ \text{y}) = \boxed{14\ \text{y}}$.

(*b*) The time for the trip in Herb's frame is $10\ \text{y} + 2(15.152\ \text{y}) = \boxed{40\ \text{y}}$.

38 •• Al and Bert are twins. Al travels at $0.600c$ to Alpha Centauri (which is 4.00 c·y from Earth as measured in the reference frame of Earth) and returns immediately. Each twin sends the other a light signal every 0.0100 y as measured in his own reference frame. (*a*) At what rate does Bert receive signals as Al is moving away from him? (*b*) How many signals does Bert receive at this rate? (*c*) How many total signals are received by Bert before Al returns to Earth? (*d*) At what rate does Al receive signals as Bert is moving away from him? (*e*) How many signals does Al receive at this rate? (*f*) How many total signals are received by Al before Al returns to Earth? (*g*) Which twin is younger at the end of the trip and by how many years?

Picture the Problem (*a*) In Bert's reference frame each successive signal from Al travels an additional distance equal to vT, where v is Al's speed and T is the interval between successive signals in Al's reference frame. We also need to take into account the dilation of the time intervals measured on Earth due to Al's motion. In Parts (*b*) and (*c*) we can use $N = f_0\Delta t_{\text{Al}}$ and $\Delta t_{\text{Al}} = \Delta t_{\text{Bert}}\sqrt{1-v^2/c^2}$ to find the number of signals received by Bert. In Parts (*d*) and (*e*) we can proceed similarly to find the number of signals received by Al and the total number he receives before he returns to Bert. Finally, we can use the number of signals each received to find the difference in their ages resulting from Al's trip.

(*a*) The rate at which Bert receives signals f_{Bert} is the reciprocal of the time between the arrival of successive signals on Earth:

$$f_{\text{Bert}} = \frac{1}{T_{\text{between signals}}}$$

The time between the arrival of successive signals on Earth is the sum of the time T between signals in Al's frame of reference and the delay introduced by the fact that Al travels a distance vT between signals:

$$T_{\text{between signals}} = T + T_{\text{delay}}$$

or, because $T_{\text{delay}} = \dfrac{vT}{c} = 0.600T$,

$$T_{\text{between signals}} = T + 0.600T = 1.600T$$

Substitute for $T_{\text{between signals}}$ to obtain:

$$f_{\text{Bert}} = \frac{1}{1.600T}$$

T, the time between the arrival of signals on Earth is related to the proper time interval T_0 (the time between signals in Al's frame of reference) through the time-dilation equation:

$$T = \frac{T_0}{\sqrt{1-\left(v^2/c^2\right)}}$$

Substituting for T and simplifying yields:

$$f_{\text{Bert}} = \frac{\sqrt{1-\left(v^2/c^2\right)}}{1.600T_0}$$

Substitute numerical values and evaluate f_{Bert}:

$$f_{\text{Bert}} = \frac{\sqrt{1-(0.600)^2}}{(1.600)(0.0100\text{ y})} = \boxed{50\text{ y}^{-1}}$$

(b) Express the number of signals N received by Bert in terms of the number of signals sent by Al:

$$N = f_0 \Delta t_{\text{Al}}$$

Use the time dilation equation to express the elapsed time in Al's frame of reference in terms of the elapsed time in Bert's frame (the proper elapsed time):

$$\Delta t_{\text{Al}} = \Delta t_{\text{Bert}} \sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute for Δt_{Al} to obtain:

$$N = f_0 \Delta t_{\text{Bert}} \sqrt{1-\left(\frac{v}{c}\right)^2} \qquad (1)$$

Find Δt_{Bert}:

$$\Delta t_{\text{Bert}} = \frac{4.00\,c\cdot\text{y}}{0.600c} = 6.667\text{ y}$$

Substitute numerical values in equation (1) and evaluate N:

$$N = \left(100\text{ y}^{-1}\right)(6.667\text{ y})\sqrt{1-\left(\frac{0.600c}{c}\right)^2}$$

$$= \boxed{533}$$

(c) Express the number of signals N received by Bert in terms of the number of signals sent by Al before he returns:

$$N = f_0 \Delta T_{\text{Al}}$$

Because $\Delta t_{\text{Al}} = \Delta t_{\text{Bert}} \sqrt{1-\left(\frac{v}{c}\right)^2}$, the time in Al's frame for the round trip $\Delta \boldsymbol{T}_{\text{Al}}$ is given by:

$$\Delta T_{\text{Al}} = 2\Delta t_{\text{Al}} = 2\Delta t_{\text{Bert}} \sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substituting for ΔT_{Al} in the expression for N yields:

$$N = 2 f_0 \Delta t_{\text{Bert}} \sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate N:

$$N = 2\left(100\ \text{y}^{-1}\right)\left(6.667\ \text{y}\right)\sqrt{1-\left(\frac{0.600c}{c}\right)^2} = \boxed{1.07\times10^3}$$

(d) Proceed as in Part (a) to find the rate at which Al receives signals as Bert is moving away from him:

$$f_{\text{Al}} = \boxed{50.0\ \text{y}^{-1}}$$

(e) Express the number of signals N received by Al:

$$N = f_{\text{Al}}\Delta t_{\text{Al}}$$

Substitute for Δt_{Al} to obtain:

$$N = f_{\text{Al}}\Delta t_{\text{Bert}}\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate N:

$$N = \left(50.0\ \text{y}^{-1}\right)\left(6.667\ \text{y}\right)\sqrt{1-\left(\frac{0.600c}{c}\right)^2} = \boxed{267}$$

(f) Express the total number of signals received by Al:

$$N_{\text{tot}} = N_{\text{outbound}} + N_{\text{return}} = 267 + N_{\text{return}}$$

The number, N_{return}, of signals received by Al on his return trip is given by:

$$N_{\text{return}} = f_{\text{Al, return}}\Delta t_{\text{Al}} = f_{\text{Al, return}}\Delta t_{\text{Bert}}\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute for N_{return} to obtain:

$$N_{\text{tot}} = 267 + f_{\text{Al, return}}\Delta t_{\text{Bert}}\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Proceeding as in Part (a), find the rate at which signals are received by Al on the return trip:

$$f_{\text{Al, return}} = 200\ \text{y}^{-1}$$

Substitute numerical values and evaluate N_{tot}:

$$N_{\text{tot}} = 267 + \left(200\ \text{y}^{-1}\right)\left(6.667\ \text{y}\right)\sqrt{1-\left(\frac{0.600c}{c}\right)^2} = 1334 = \boxed{1.33\times10^3}$$

(*g*) Their age difference is:

$$\Delta t = \Delta t_{\text{Bert}} - \Delta t_{\text{Al}}$$

Substitute numerical values to obtain:

$$\Delta t = \frac{1334}{100\ \text{y}^{-1}} - \frac{1067}{100\ \text{y}^{-1}} = 2.67\ \text{y}$$

and

$$\boxed{\text{Al is } 2.67\ \text{y younger than Bert.}}$$

Relativistic Energy and Momentum

39 • Find the ratio of the total energy to the rest energy of a particle of mass *m* moving with speed (*a*) 0.100*c*, (*b*) 0.500*c*, (*c*) 0.800*c*, and (*d*) 0.990*c*.

Picture the Problem We can use Equation R-15 to find the ratio of the total energy to the rest energy for the given particle.

From Equation R-15:

$$E = \frac{mc^2}{\sqrt{1-\frac{v^2}{c^2}}} = \frac{E_0}{\sqrt{1-\frac{v^2}{c^2}}}$$

Solve for the ratio of E to E_0 to obtain:

$$\frac{E}{E_0} = \frac{1}{\sqrt{1-\frac{v^2}{c^2}}}$$

(*a*) Evaluate E/E_0 for $v = 0.100c$:

$$\left.\frac{E}{E_0}\right]_{v=0.100c} = \frac{1}{\sqrt{1-\frac{(0.100c)^2}{c^2}}} = \boxed{1.01}$$

(*b*) Evaluate E/E_0 for $v = 0.500c$:

$$\left.\frac{E}{E_0}\right]_{v=0.500c} = \frac{1}{\sqrt{1-\frac{(0.500c)^2}{c^2}}} = \boxed{1.15}$$

(*c*) Evaluate E/E_0 for $v = 0.800c$:

$$\left.\frac{E}{E_0}\right]_{v=0.800c} = \frac{1}{\sqrt{1-\frac{(0.800c)^2}{c^2}}} = \boxed{1.67}$$

(*d*) Evaluate E/E_0 for $v = 0.990c$:

$$\left.\frac{E}{E_0}\right]_{v=0.999c} = \frac{1}{\sqrt{1-\frac{(0.990c)^2}{c^2}}} = \boxed{7.09}$$

40 • A proton (rest energy 938 MeV) has a total energy of 1400 MeV. (*a*) What is its speed? (*b*) What is its momentum?

Picture the Problem The rest energy E_0 is equal to mc^2. We are given E_0 and E, where E_0 = 938 MeV and the total energy E = 1400 MeV. (The total energy is the rest energy plus the kinetic energy). We can find the momentum p of the proton using $E^2 = p^2c^2 + m^2c^4$ (Equation R-17), and once we have p we can solve for the speed v using $v/c = pc/E$ (Equation R-16).

(*b*) Use Equation R-17 to relate the momentum to the total energy and the rest energy:

$$E^2 = p^2c^2 + m^2c^4 \text{ and } E_0 = mc^2$$

so

$$E^2 = p^2c^2 + E_0^2 \Rightarrow p = \frac{\sqrt{E^2 - E_0^2}}{c}$$

Substitute numerical values and evaluate p:

$$p = \frac{\sqrt{(1400\text{ Mev})^2 - (938\text{ Mev})^2}}{c}$$
$$= 1039\text{ MeV}/c$$
$$= \boxed{1040\text{ MeV}/c}$$

(*a*) Use Equation R-16 to express the speed of the proton:

$$\frac{v}{c} = \frac{pc}{E} \Rightarrow v = \left(\frac{pc}{E}\right)c$$

Substitute numerical values and evaluate v:

$$v = \left(\frac{(1039\text{ MeV}/c)}{1400\text{ MeV}}\right)c = \boxed{0.742c}$$

41 • **[SSM]** How much energy would be required to accelerate a particle of mass m from rest to (*a*) 0.500c, (*b*) 0.900c, and (*c*) 0.990c? Express your answers as multiples of the rest energy, mc^2.

Picture the Problem We can use Equation R-14 to find the energy required to accelerate this particle from rest to the given speeds.

From Equation R-14 we have:

$$K = \frac{mc^2}{\sqrt{1-(v/c)^2}} - mc^2$$
$$= \left(\frac{1}{\sqrt{1-(v/c)^2}} - 1\right)mc^2$$

(*a*) Substitute numerical values and evaluate $K(0.500c)$:

$$K(0.500c)=\left(\frac{1}{\sqrt{1-(0.500c/c)^2}}-1\right)mc^2=\boxed{0.155mc^2}$$

(*b*) Substitute numerical values and evaluate $K(0.900c)$:

$$K(0.900c)=\left(\frac{1}{\sqrt{1-(0.900c/c)^2}}-1\right)mc^2=\boxed{1.29mc^2}$$

(*c*) Substitute numerical values and evaluate $K(0.990c)$:

$$K(0.990c)=\left(\frac{1}{\sqrt{1-(0.990c/c)^2}}-1\right)mc^2=\boxed{6.09mc^2}$$

42 • If the kinetic energy of a particle equals its rest energy, what percentage error is made by using $p = mv$ for its momentum? Is the non-relativistic expression always low or high compared to the relativistically correct expression for momentum?

Picture the Problem We can use Equations R-10 and R-14 to express the error made in using $p = mv$ for the momentum of the particle when $K = E_0$.

The error in using $p = mv$ for the momentum of the particle is given by:

$$\frac{p_{\text{rel}}-p}{p_{\text{rel}}}=1-\frac{p}{p_{\text{rel}}} \qquad (1)$$

From Equation R-14 we have:

$$K=\frac{mc^2}{\sqrt{1-(v/c)^2}}-mc^2=\left(\frac{1}{\sqrt{1-(v/c)^2}}-1\right)mc^2$$

For $K = E_0$:

$$K=\left(\frac{1}{\sqrt{1-(v/c)^2}}-1\right)K$$

or

$$\frac{1}{\sqrt{1-(v/c)^2}}=2$$

From Equation R-10, the relativistic momentum of the particle is:

$$p_{\text{rel}} = \frac{mv}{\sqrt{1-(v/c)^2}} = 2mv$$

Substitute in equation (1) and simplify to obtain:

$$1-\frac{p}{p_{\text{rel}}} = 1-\frac{mv}{2mv} = \boxed{50\%}$$

The ratio of the non-relativistic momentum of a particle to its relativistic momentum is given by:

$$\frac{p}{p_{\text{rel}}} = \frac{p}{\dfrac{p}{\sqrt{1-v^2/c^2}}} = \sqrt{1-v^2/c^2}$$

Because $\sqrt{1-v^2/c^2} < 1$, the non-relativistic expression is always low compared to the relativistically correct expression for momentum.

43 • What is the total energy of a proton whose momentum is $3mc$?

Picture the Problem We can use Equation R-17 to find the total energy of any proton whose momentum is given. See Problem 42 for the rest energy of a proton.

The total energy, momentum, and rest energy of the proton are related by Equation R-17:

$$E^2 = p^2c^2 + (mc^2)^2$$

Substitute for the momentum of the proton:

$$E^2 = (3mc)^2c^2 + (mc^2)^2 = 9m^2c^4 + m^2c^4 = 10m^2c^4$$

Solving for E yields:

$$E = \sqrt{10}mc^2$$

Substitute for m and evaluate E:

$$E = \sqrt{10}(938\,\text{MeV}/c^2)c^2 = \boxed{2.97\,\text{GeV}}$$

44 •• Using a **spreadsheet** program or graphing calculator, make a graph of the kinetic energy of a particle with rest energy of 100 MeV for speeds between 0 and c. On the same graph, plot $\frac{1}{2}mv^2$ by way of comparison. Using the graph, estimate at about what speed the non-relativistic expression is no longer a good approximation to the kinetic energy. As a suggestion, plot the energy in units of MeV and the speed in the dimensionless form v/c.

Picture the Problem We can create a spreadsheet program to plot both the classical and relativistic kinetic energy of the particle.

The relativistic kinetic energy of the particle is given by:

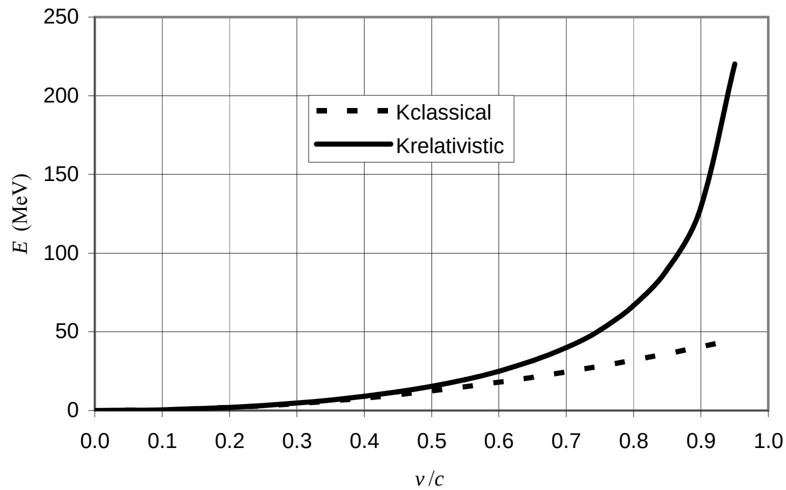
$$K_{\text{relativistic}} = mc^2\left(\frac{1}{\sqrt{1-(v/c)^2}}-1\right)$$

A spreadsheet program to graph $K_{\text{relativistic}}$ and $K_{\text{classical}}$ is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
A8	A7+0.05	$v/c + 0.05$
B7	0.5*$B$3*A7^2	$\frac{1}{2}mv^2$
C7	$B$3*(1/((1–A7^2)^0.5)–1)	$mc^2\left(\frac{1}{\sqrt{1-(v/c)^2}}-1\right)$

	A	B	C
1			
2			
3	mc^2=	100	MeV
4			
5	v/c	$\frac{1}{2}mv^2$	$\left(\frac{1}{\sqrt{1-(v/c)^2}}\right)mc^2$
6		$K_{\text{classical}}$	$K_{\text{relativistic}}$
7	0.00	0.00	0.00
8	0.05	0.13	0.13
9	0.10	0.50	0.50
10	0.15	1.13	1.14
23	0.80	32.00	66.67
24	0.85	36.13	89.83
25	0.90	40.50	129.42
26	0.95	45.13	220.26

The solid curve is the graph of the relativistic kinetic energy. The relativistic formula, represented by the continuous curve, begins to deviate from the classical curve around $v/c \approx 0.4$.



45 •• **[SSM]** (*a*) Show that the speed *v* of a particle of mass *m* and total energy *E* is given by $\frac{v}{c}=\left[1-\frac{\left(mc^2\right)^2}{E^2}\right]^{1/2}$ and that when *E* is much greater than mc^2, this can be approximated by $\frac{v}{c}\approx 1-\frac{\left(mc^2\right)^2}{2E^2}$. Find the speed of an electron with kinetic energy of (*b*) 0.510 MeV and (*c*) 10.0 MeV.

Picture the Problem We can solve the equation for the relativistic energy of a particle to obtain the first result and then use the binomial expansion subject to $E >> mc^2$ to obtain the second result. In Parts (*b*) and (*c*) we can use the first expression obtained in (*a*), with $E = E_0 + K$, to find the speeds of electrons with the given kinetic energies. See Table 39-1 for the rest energy of an electron.

(*a*) The relativistic energy of a particle is given by Equation R-15:

$$E=\frac{mc^2}{\sqrt{1-\frac{v^2}{c^2}}}$$

Solving for *v*/*c* yields:

$$\frac{v}{c}=\boxed{\left[1-\frac{\left(mc^2\right)^2}{E^2}\right]^{1/2}} \quad (1)$$

Expand the radical expression binomially to obtain:

$$\frac{v}{c}=\sqrt{1-\frac{\left(mc^2\right)^2}{E^2}}=1-\frac{1}{2}\frac{\left(mc^2\right)^2}{E^2}+\text{higher-order terms}$$

Because the higher-order terms are much smaller than the 2nd-degree term when $E >> mc^2$:

$$\frac{v}{c} \approx \boxed{1 - \frac{\left(mc^2\right)^2}{2E^2}}$$

(*b*) Solve equation (1) for *v*:

$$v = c\sqrt{1 - \frac{\left(mc^2\right)^2}{E^2}}$$

Because $E = E_0 + K$:

$$v = c\sqrt{1 - \frac{E_0^2}{\left(E_0 + K\right)^2}} = c\sqrt{1 - \frac{1}{\left(1 + \frac{K}{E_0}\right)^2}}$$

For an electron whose kinetic energy is 0.510 MeV:

$$v(0.510\,\text{MeV}) = c\sqrt{1 - \frac{1}{\left(1 + \frac{0.510\,\text{MeV}}{0.511\,\text{MeV}}\right)^2}} = \boxed{0.866c}$$

(*c*) For an electron whose kinetic energy is 10.0 MeV:

$$v(10.0\,\text{MeV}) = c\sqrt{1 - \frac{1}{\left(1 + \frac{10.0\,\text{MeV}}{0.511\,\text{MeV}}\right)^2}} = \boxed{0.999c}$$

46 •• Use the binomial expansion and Equation R-17 to show that when $pc << mc^2$, the total energy is given approximately by $E \approx mc^2 + p^2/(2m)$.

Picture the Problem We can solve Equation R-17 for *E* and factor $\left(mc^2\right)^2$ from under the resulting radical to obtain an expression to which we can apply the binomial expansion to write the radical expression as a power series. Finally, we can invoke the condition that $pc << mc^2$ to complete the argument that the total energy is given approximately by $E \approx mc^2 + p^2/(2m)$.

From Equation R-17 we have:

$$E = \sqrt{p^2c^2 + \left(mc^2\right)^2}$$

Factor $\left(mc^2\right)^2$ under the radical and simplify to obtain:

$$E = \sqrt{\left(mc^2\right)^2\left[\frac{p^2c^2}{\left(mc^2\right)^2} + 1\right]} = mc^2\sqrt{\frac{p^2c^2}{\left(mc^2\right)^2} + 1} = mc^2\sqrt{1 + \frac{p^2}{mc^2}}$$

Expand the radical factor binomially to obtain:

$$\left(1+\frac{p^2}{m^2c^2}\right)^{1/2}=1+\frac{1}{2}\frac{p^2}{m^2c^2}+\text{higher - order terms}$$

For $pc << mc^2$:

$$\left(1+\frac{p^2}{m^2c^2}\right)^{1/2}\approx 1+\frac{1}{2}\frac{p^2}{m^2c^2}$$

Substituting for $\left(1+\frac{p^2}{m^2c^2}\right)^{1/2}$ and simplifying yields:

$$E=mc^2\left(1+\frac{1}{2}\frac{p^2}{m^2c^2}\right)=\boxed{mc^2+\frac{p^2}{2m}}$$

$$=\text{rest energy}+\text{classical kinetic energy}$$

47 •• Derive the equation $E^2 = p^2c^2 + m^2c^4$ (Equation R-17) by eliminating v from Equations R-10 and R-16.

Picture the Problem We can solve Equation R-16 for v and substitute in Equation R-10 to eliminate v. Simplification of the resulting expression leads to $E^2 = p^2c^2 + \left(mc^2\right)^2$.

Express the relativistic momentum of a particle using Equation R-10:

$$p=\frac{mv}{\sqrt{1-v^2/c^2}}$$

From Equation R-16 we have:

$$\frac{v}{c}=\frac{pc}{E}\Rightarrow v=\frac{pc^2}{E}$$

Substitute for v and simplify to obtain:

$$p=\frac{m\dfrac{pc^2}{E}}{\sqrt{1-\dfrac{\left(pc^2/E\right)^2}{c^2}}}$$

or

$$1=\frac{mc^2}{E\sqrt{1-\dfrac{p^2c^2}{E^2}}}$$

Multiply both sides of the equation by $E\sqrt{1-\frac{p^2c^2}{E^2}}$:

$$E\sqrt{1-\frac{p^2c^2}{E^2}}=mc^2$$

Square both sides of the equation:

$$E^2\left(1-\frac{p^2c^2}{E^2}\right)=\left(mc^2\right)^2$$

Solve for E^2 to obtain Equation R-17:

$$E^2=\boxed{p^2c^2+\left(mc^2\right)^2}$$

48 •• The rest energy of a proton is about 938 MeV. If its kinetic energy is also 938 MeV, find (*a*) its momentum and (*b*) its speed.

Picture the Problem (*a*) We can solve the relation for total energy, momentum, and rest energy of the proton for its momentum and evaluate this expression for $K = E_0$. In Part (*b*) we can equate the expression for the momentum of the proton under the conditions that exist in this problem with the general expression for the relativistic momentum of the proton and solve the resulting equation for the speed of the proton.

(*a*) Relate the total energy, momentum, and rest energy of a proton:

$$E^2=p^2c^2+\left(mc^2\right)^2$$

Solving for p yields:

$$p=\frac{\sqrt{E^2-E_0^2}}{c}=\frac{\sqrt{\left(E_0+K\right)^2-E_0^2}}{c}$$
$$=\frac{\sqrt{K^2+2E_0K}}{c}$$

If $K = E_0$:

$$p_{K=E_0}=\frac{\sqrt{E_0^2+2E_0^2}}{c}=\frac{\sqrt{3}E_0}{c}$$

Substitute numerical values and evaluate p:

$$p_{K=E_0}=\frac{\sqrt{3}\left(938\text{ MeV}\right)}{c}$$
$$=\boxed{1.62\text{ GeV}/c}$$

(*b*) In Part (*a*) we established that the momentum of the proton is given by:

$$p_{K=E_0}=\frac{\sqrt{3}E_0}{c}$$

Substituting for E_0 and simplifying yields:

$$p_{K=E_0}=\frac{\sqrt{3}mc^2}{c}=\sqrt{3}mc$$

The relativistic momentum of the proton is also given by:

$$p = \frac{mc}{\sqrt{1 - \frac{v^2}{c^2}}}$$

Equating these expressions gives:

$$\sqrt{3}mc = \frac{mc}{\sqrt{1 - \frac{v^2}{c^2}}}$$

Solve for v to obtain:

$$v = \frac{\sqrt{3}}{2}c = \boxed{0.866c}$$

49 •• What percentage error is made in using $\frac{1}{2}mv^2$ for the kinetic energy of a particle if its speed is (*a*) 0.10*c* and (*b*) 0.90*c*?

Picture the Problem We can use the expressions for the classical and relativistic kinetic energies of a particle to obtain a general expression for the fractional error made in using $\frac{1}{2}mv^2$ for the kinetic energy of a particle as a function of its speed.

The percentage error made in using $\frac{1}{2}mv^2$ for the kinetic energy of a particle is given by:

$$\frac{\Delta K}{K_{\text{rel}}} = \left|\frac{K_{\text{rel}} - K_{\text{classical}}}{K_{\text{rel}}}\right| = \left|1 - \frac{K_{\text{classical}}}{K_{\text{rel}}}\right|$$

The relativistic kinetic energy of the particle is given by Equation R-14:

$$K_{\text{rel}} = \frac{mc^2}{\sqrt{1-(v/c)^2}} - mc^2$$

$$= \left(\frac{1}{\sqrt{1-(v/c)^2}} - 1\right)mc^2$$

Substitute for K_{rel} in the expression for $\dfrac{\Delta K}{K_{\text{rel}}}$ and simplify to obtain:

$$\frac{\Delta K}{K_{\text{rel}}} = \left|1 - \frac{\frac{1}{2}mv^2}{\left(\frac{1}{\sqrt{1-(v/c)^2}} - 1\right)mc^2}\right| = \left|1 - \frac{v^2}{2\left(\frac{1}{\sqrt{1-(v/c)^2}} - 1\right)c^2}\right|$$

(a) Evaluate f for $v = 0.10c$:

$$f(0.10c) = \left| 1 - \frac{(0.10c)^2}{2\left(\frac{1}{\sqrt{1-(0.10)^2}} - 1\right)c^2} \right| = \boxed{0.75\%}$$

(b) Evaluate f for $v = 0.90c$:

$$f(0.90c) = \left| 1 - \frac{(0.90c)^2}{2\left(\frac{1}{\sqrt{1-(0.90)^2}} - 1\right)c^2} \right| = \boxed{69\%}$$

General Problems

50 • A spaceship departs from Earth for the star Alpha Centauri, which is 4.0 $c{\cdot}$y away in the reference frame of Earth. The spaceship travels at 0.75c. How long does it take to get there (a) as measured on Earth and (b) as measured by a passenger on the spaceship?

Picture the Problem We can find the duration of the trip, as measured on Earth, using the definition of average speed; that is, $\Delta t = L/v$. The elapsed time measured by the passenger is the proper time and is related to Δt through the time dilation equation (Equation R-3).

(a) Relate the time Δt for the trip as measured on Earth to its length L and the speed u of the spaceship:

$$\Delta t = \frac{L}{v}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{4.0\,c\cdot\text{y}}{0.75c} = 5.33\,\text{y} = \boxed{5.3\,\text{y}}$$

(b) Use Equation R-3, the time dilation equation, to express the proper time measured by a passenger:

$$\Delta t_0 = \Delta t\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate Δt_0:

$$\Delta t_\text{p} = (5.33\,\text{y})\sqrt{1-\frac{(0.75c)^2}{c^2}} = \boxed{3.5\,\text{y}}$$

51 • The total energy of a particle is three times its rest energy. (*a*) Find v/c for the particle. (*b*) Show that its momentum is given by $p = \sqrt{8}mc$.

Picture the Problem (*a*) We can solve the expression for the relativistic energy of the particle for v/c and evaluate this expression for $E = 3E_0$. In Part (*b*) we can solve the expression relating the total energy, momentum, and rest energy of the particle for p and evaluate it for $E = 3E_0$ to show that its momentum is given by $p = \sqrt{8}\,mc$.

(*a*) The relativistic energy of the particle is given by Equation R-15:

$$E = \frac{mc^2}{\sqrt{1 - v^2/c^2}} = \frac{E_0}{\sqrt{1 - v^2/c^2}}$$

Solving for v/c yields:

$$\frac{v}{c} = \sqrt{1 - \frac{E_0^2}{E^2}}$$

For $E = 3E_0$:

$$\frac{v}{c} = \sqrt{1 - \frac{E_0^2}{9E_0^2}} = \sqrt{0.889} = \boxed{0.943}$$

(*b*) Equation R-17 relates the total energy, momentum, and rest energy of the particle:

$$E^2 = p^2c^2 + \left(mc^2\right)^2 = p^2c^2 + E_0^2$$

Solving for p yields:

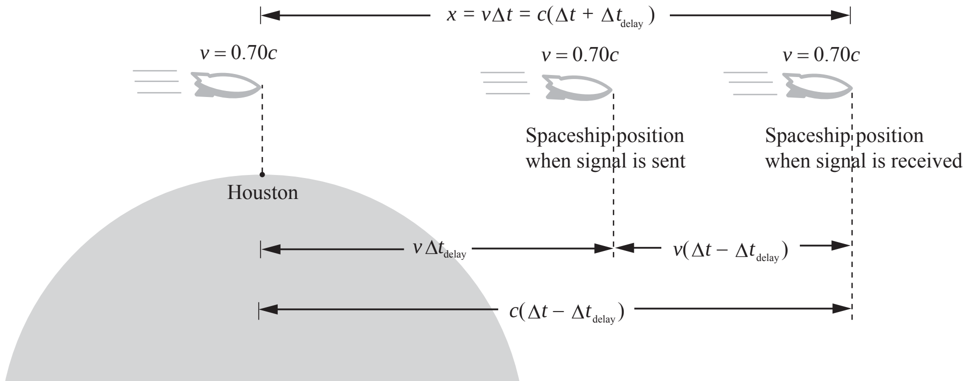
$$p = \frac{\sqrt{E^2 - E_0^2}}{c}$$

Evaluating p for $E = 3E_0$ yields:

$$p = \frac{\sqrt{(3E_0)^2 - E_0^2}}{c} = \frac{\sqrt{8}E_0}{c} = \frac{\sqrt{8}mc^2}{c}$$
$$= \boxed{\sqrt{8}mc}$$

52 •• A spaceship travels past Earth moving at $0.70c$ relative to Earth. 5.0 minutes after the spaceship passes closest to Earth, a message is sent from Houston, Texas, to the craft. (Neglect all effects of the rotational motion of Earth.) (*a*) How long does it take for the signal to arrive? (*b*) The spaceship and the control center agree on the time when the ship passes closest to Earth. Five minutes after the message is received aboard the ship, a return message is sent by the ship back to Houston. What is the time interval in Houston between the time their message was sent, and the time the return message is received?

Picture the Problem The pictorial representation summarizes the information given in the problem statement. Note that the spaceship, moving at $0.70c$, has a 5.0 min head start. This means that, in the Earth frame of reference, the message is received by the spaceship after a time Δt has passed since the spaceship passed closest to Earth. In Part (*b*) we'll have to determine the time-dilated interval of 5.0 min aboard the spaceship.



(*a*) The distance Δx from Earth to the ship is given by:

$$\Delta x = c\left(\Delta t - \Delta t_{\text{delay}}\right)$$

Δx is also given by:

$$\Delta x = v\Delta t$$

Equate these expressions to obtain:

$$c\left(\Delta t - \Delta t_{\text{delay}}\right) = v\Delta t \Rightarrow \Delta t = \frac{\Delta t_{\text{delay}}}{1 - \frac{v}{c}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{5.0\text{ min}}{1 - \frac{0.70c}{c}} = 16.67\text{ min}$$

$$= \boxed{17\text{ min}}$$

(*b*) Express the total time from the sending of the original message (5.0 min after the closest passage) to the receipt of the return message:

$$\Delta t_{\text{tot}} = \Delta t_{\text{to ship}} + \Delta t_{\text{return}} - 5.0\text{ min} \qquad (2)$$

According to observers on Earth, the time between receipt of the message and its return is:

$$\Delta t_{\text{return}} = \frac{5.0\text{ min}}{\sqrt{1-\left(\frac{v}{c}\right)^2}} = \frac{5.0\text{ min}}{\sqrt{1-(0.70)^2}}$$
$$= 7.001\text{ min}$$

and

$$\Delta t_{\text{to ship}} = 16.67\text{ min} + 7.001\text{ min}$$
$$= 23.67\text{ min}$$

In Earth's frame of reference, the spaceship is at a distance from Earth given by:

$$\Delta x_{\text{to ship}} = v\Delta t_{\text{to ship}} = 0.70c\Delta t_{\text{to ship}}$$

Substitute numerical values and evaluate $\Delta x_{\text{to ship}}$:

$$\Delta x_{\text{to ship}} = (0.70)(2.998\times10^8\text{ m/s})\left(23.67\text{ min}\times\frac{60\text{ s}}{\text{min}}\right) = 2.980\times10^{11}\text{ m}$$

The time for the signal to return to Earth from this distance is:

$$\Delta t_{\text{return message}} = \frac{\Delta x}{c} = \frac{2.980\times10^{11}\text{ m}}{2.998\times10^8\text{ m/s}}$$
$$= 994\text{ s} = 17\text{ min}$$

Substitute numerical values in equation (2) and evaluate Δt_{tot}:

$$\Delta t_{\text{tot}} = 19\text{ min} + 17\text{ min} - 5.0\text{ min}$$
$$= \boxed{31\text{ min}}$$

53 •• [SSM] Particles called muons traveling at 0.99995c are detected at the surface of Earth. One of your fellow students claims that the muons might have originated from the Sun. Prove him wrong. (The proper mean lifetime of the muon is 2.20 μs.)

Picture the Problem Your fellow student is thinking that the time dilation factor might allow muons to travel the 150,000,000,000 m from the Sun to Earth. You can discredit your classmate's assertion by considering the mean lifetime of the muon from Earth's reference frame. Doing so will demonstrate that the distance traveled during as many as 5 proper mean lifetimes is consistent with the origination of muons within Earth's atmosphere.

The distance, in the Earth frame of reference, a muon can travel in n mean lifetimes τ is given by:

$$d = n\frac{d_0}{\sqrt{1-(v/c)^2}} = \frac{nv\tau}{\sqrt{1-(v/c)^2}} = \frac{n(v/c)c\tau}{\sqrt{1-(v/c)^2}}$$

Substitute numerical values for v, c, and τ and simplify to obtain:

$$d = n\frac{(0.99995)(2.998\times10^8\ \text{m/s})(2.20\ \mu\text{s})}{\sqrt{1-(0.99995)^2}} = (66.0\ \text{km})n$$

In 5 lifetimes a muon would travel a distance:

$d = (66.0\ \text{km})(5) = 330\ \text{km}$, a distance approximating a low-Earth orbit.

In 100 lifetimes, $d \approx 6600$ km, or approximately one Earth radius. This relatively short distance should convince your classmate that the origin of the muons that are observed on Earth is within our atmosphere and that they certainly are not from the Sun.

54 •• (*a*) How tall is Mount Everest in a reference frame traveling with a cosmic ray muon that is traveling straight down, relative to Earth, at 0.99c? Take the height of Mount Everest according to an Earth-based observer to be 8846 m. (*b*) How long does it take the muon to travel the height of the mountain from the reference frame traveling with the muon? (*c*) How long does it take the muon to travel the height of the mountain from the Earth-based reference frame?

Picture the Problem Apply the length contraction equation to find the height of Mount Everest in the frame of reference traveling with the muon and use the relationship between the distance an object travels, its speed, and the elapsed time to solve Parts (*b*) and (*c*).

(*a*) The height h of Mount Everest in the frame of reference traveling with the muon is given by:

$$h = \sqrt{1-(v/c)^2}\,h_0$$

where h_0 is the height of Mount Everest in Earth's frame of reference.

Substitute numerical values and evaluate h:

$$h = \sqrt{1-(0.99)^2}\,(8.846\ \text{km}) = 1.248\ \text{km}$$
$$= \boxed{1.2\ \text{km}}$$

(*b*) In the frame of reference traveling with the muon, the mountain is traveling toward it at a speed of 0.99*c*. Hence the time to travel the height of the mountain is given by:

$$\Delta t_{\text{muon frame}} = \frac{h}{v_{\text{mountain}}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t_{\text{muon frame}} = \frac{1.248\ \text{km}}{0.99\left(2.998\times10^{8}\ \text{m/s}\right)} = \boxed{4.2\ \mu\text{s}}$$

(*c*) From the Earth-based reference frame, the time it takes the muon to travel the height of the mountain is the ratio of the height of the mountain to the speed of the muon:

$$\Delta t_{\text{earth frame}} = \frac{h_0}{v_{\text{muon}}}$$

Substitute numerical values and evaluate $\Delta t_{\text{earth frame}}$:

$$\Delta t_{\text{earth frame}} = \frac{8.846\ \text{km}}{(0.99)\left(2.998\times10^{8}\ \text{m/s}\right)} = \boxed{30\ \mu\text{s}}$$

55 ••• A gold nucleus has a radius of 3.00×10^{-14} m, and a mass of 197 amu. (1 amu has a rest energy of 932 MeV.) During experiments at Brookhaven National Laboratory, these nuclei are routinely accelerated to a kinetic energy of 3.35×10^{4} GeV. (*a*) How much less than the speed of light are they traveling? (*b*) At these energies, how long does it take them to travel 100 m in the laboratory frame?

Picture the Problem We can apply Equation R-15, the expression for the total relativistic energy of a particle, to find how much less than the speed of light the gold nuclei are traveling. The time it takes the nuclei to travel 100 m in the laboratory frame can be found using the distance, rate, and time equation.

(*a*) Express the difference between the speed of light and the speed of the gold nucleus:

$$\Delta v = c - v \qquad (1)$$

The total relativistic energy of a gold nucleus is given by Equation R-15:

$$K + mc^2 = \frac{mc^2}{\sqrt{1-(v/c)^2}}$$

Solving for $\sqrt{1-(v/c)^2}$ yields:

$$\sqrt{1-(v/c)^2} = \frac{\frac{mc^2}{K}}{1+\frac{mc^2}{K}} \qquad (2)$$

Evaluate $\frac{mc^2}{K}$ to obtain:

$$\frac{mc^2}{K} = \frac{(197\text{ amu})(932\text{ MeV/amu})}{3.35\times10^4\text{ GeV}} = 5.48\times10^{-3} << 1$$

Because $mc^2 << K$, equation (2) can be approximated by:

$$\sqrt{1-(v/c)^2} \approx \frac{mc^2}{K} \qquad (3)$$

Solve for v/c to obtain:

$$\frac{v}{c} = \sqrt{1-\left(\frac{mc^2}{K}\right)^2}$$

Expanding the radical binomially yields:

$$\left[1-\left(\frac{mc^2}{K}\right)^2\right]^{\frac{1}{2}} = 1-\frac{1}{2}\left(\frac{mc^2}{K}\right)^2 + \text{higher order terms}$$

Because $mc^2 << K$:

$$\left[1-\left(\frac{mc^2}{K}\right)^2\right]^{\frac{1}{2}} \approx 1-\frac{1}{2}\left(\frac{mc^2}{K}\right)^2$$

and

$$v = c\left[1-\frac{1}{2}\left(\frac{mc^2}{K}\right)^2\right]$$

Substituting for v in equation (1) yields:

$$\Delta v = c - c\left[1-\frac{1}{2}\left(\frac{mc^2}{K}\right)^2\right] = \frac{1}{2}\left(\frac{mc^2}{K}\right)^2 c$$

Substitute numerical values and evaluate Δv:

$$\Delta v = \frac{1}{2}\left(\frac{197\text{ amu}\times932\text{ MeV/amu}}{3.35\times10^4\text{ GeV}}\right)^2\left(2.998\times10^8\text{ m/s}\right) = \boxed{4.50\text{ km/s}}$$

(*b*) Because the nuclei are, to three significant figures, traveling at the speed of light:

$$\Delta t \approx \frac{\Delta x}{c} = \frac{100\ \text{m}}{2.998\times 10^{8}\ \text{m/s}} = \boxed{0.334\ \mu\text{s}}$$

56 ••• Consider the flight of a beam of neutrons produced in a nuclear reactor. These neutrons have kinetic energies of up to 1.00 MeV. The rest energy of a neutron is 939 MeV. (*a*) What is the speed of 1.00 MeV neutrons? Express your answer in terms of *v*/*c*. (*b*) If the average lifetime of such a neutron is 15.0 min, what is the maximum length of a beam of such neutrons (in a vacuum, in the absence of any interactions between the neutrons and other material)? Estimate this maximum range by calculating the length corresponding to five mean lifetimes. After five mean lifetimes only e^{-5} or 0.007 (0.7%) of the neutrons remain. (*c*) Compare this to the range of so-called ″thermally moderated″ neutrons, whose kinetic energies are around 0.025 eV. Express your answer as a percentage. That is, what percent of the 1.00 MeV-neutron range is the thermally moderated-neutron range? (Note that our assumption of a vacuum continues, however in reality neutrons of this energy interact readily with matter, such as air or water, and ″real″ ranges are much shorter.)

Picture the Problem We can apply $K + mc^2 = mc^2 \Big/ \sqrt{1-(v/c)^2}$, the expression for the total relativistic energy of a particle, to find the speed of 1.00 MeV neutrons. We can use the equation relating distance, rate, and time to estimate their maximum beam length. Finally, we can use the non-relativistic expression for their kinetic energy to find the range of ″thermally moderated″ neutrons.

(*a*) The total relativistic energy of a neutron is given by Equation R-15:

$$K + mc^2 = \frac{mc^2}{\sqrt{1-(v/c)^2}}$$

Solving for *v*/*c* yields:

$$\frac{v}{c} = \sqrt{1-\left(\frac{1}{1+\dfrac{K}{mc^2}}\right)^2}$$

Substitute numerical values and evaluate *v*/*c*:

$$\frac{v}{c} = \sqrt{1-\left(\frac{1}{1+\dfrac{1.00\ \text{MeV}}{939\ \text{MeV}}}\right)^2} = \boxed{4.61\%}$$

(*b*) Express the maximum expected beam length of the neutrons as a function of the number *n* of lifetimes:

$$\Delta x = n\left(\frac{v}{c}\right)c\Delta t \qquad (1)$$

Evaluate this expression for $n = 5$:

$$\Delta x = (5)(0.0461)\left(2.998\times10^{8}\ \text{m/s}\right)\left(15.0\ \text{min}\times\frac{60\ \text{s}}{\text{min}}\right) = \boxed{6.22\times10^{10}\ \text{m}}$$

(*c*) Express the ratio *r* of the range of "thermally moderated" neutrons to the range of 1.00 MeV neutrons:

$$r = \frac{\Delta x_{\text{thermally moderated}}}{\Delta x_{1.00\ \text{MeV}}} \qquad (2)$$

Because the energy of the "thermally moderated" neutrons is 0.025 eV, we can use the non-relativistic equation for their kinetic energy:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}m\left(\frac{v}{c}\right)^2 c^2 \Rightarrow \frac{v}{c} = \sqrt{\frac{2K}{mc^2}}$$

Substitute for v/c in equation (1) to obtain:

$$\Delta x_{\text{thermally moderated}} = n\sqrt{\frac{2K}{mc^2}}c\Delta t$$

Substitute numerical values and evaluate $\Delta x_{\text{thermally moderated}}$:

$$\Delta x_{\text{thermally moderated}} = 5\sqrt{\frac{2(0.025\ \text{eV})}{939\ \text{MeV}}}\left(2.998\times10^{8}\ \text{m/s}\right)(15.0\ \text{min})\left(\frac{60\ \text{s}}{\text{min}}\right) = 9.84\times10^{6}\ \text{m}$$

Substitute numerical values in equation (2) and evaluate *r*:

$$r = \frac{9.84\times10^{6}\ \text{m}}{6.22\times10^{10}\ \text{m}} = \boxed{0.016\%}$$

57 ••• You and Ernie are trying to fit a 15-ft-long ladder into a 10-ft-long shed with doors at each end. You suggest to Ernie that you open the front door to the shed and have him run toward it with the ladder at a speed such that the length contraction of the ladder shortens it enough so that it fits in the shed. As soon as the back end of the ladder passes through the door, you will slam it shut. (*a*) What is the minimum speed at which Ernie must run to fit the ladder into the shed? Express it as a fraction of the speed of light. (*b*) As Ernie runs toward the shed at a speed of 0.866*c*, he realizes that in the reference frame of the ladder, it is the *shed* which is shorter, not the ladder. How long is the shed in the rest frame of the ladder? (*c*) In the reference frame of the ladder is there any instant that

both ends of the ladder are simultaneously inside the shed? Examine this from the point of view of relativistic simultaneity.

Picture the Problem Let the letter ″L″ denote the ladder and the letter ″S″ the shed. We can apply the length contraction equation to the determination of the minimum speed at which Ernie must run to fit the ladder into the shed as well as the length of the shed in rest frame of the ladder.

(*a*) Express the length L_L of the shed in Ernie's frame of reference in terms of its proper length $L_{L,0}$:

$$L_L = L_{L,0}\sqrt{1-\left(\frac{v}{c}\right)^2} \Rightarrow v = c\sqrt{1-\frac{L_L^2}{L_{L,0}^2}}$$

Substitute numerical values and evaluate v:

$$v = c\sqrt{1-\left(\frac{10\,\text{ft}}{15\,\text{ft}}\right)^2} = \boxed{0.75c}$$

(*b*) Express the length L_S of the shed in the rest frame of the ladder in terms of its proper length $L_{L,0}$:

$$L_S = L_{S,0}\sqrt{1-\frac{v^2}{c^2}}$$

Substitute numerical values and evaluate L_S:

$$L_S = (10\,\text{ft})\sqrt{1-\left(\frac{0.866c}{c}\right)^2} = \boxed{5.0\,\text{ft}}$$

(*c*) No. In your rest frame, the back end of the ladder will clear the door before the front end hits the wall of the shed, while in Ernie's rest frame, the front end will hit the wall of the shed while the back end has yet to clear the other door.

Let the ladder be traveling from left to right. To ″explain″ the simultaneity issue we first describe the situation in the reference frame of the shed. In this frame the ladder has length L_L = 7.5 m and the shed has length $L_{S,0}$ = 10 m. We (mentally) put a clock at each end of the shed. Let both clocks read zero at the instant the left end of the ladder enters the shed. At this instant the right end of the ladder is a distance $L_{S,0} - L_L$ = 2.5 m from the right end of the shed. At the instant the right end of the ladder exits the shed both clocks read Δt, where $\Delta t = (L_{S,0} - L_L)/v = 9.63\,\text{ns}$. There are two space-time coincidences to consider: the left end of the ladder enters the shed and the clock at the left end of the shed reads zero, and the right end of the ladder exits the shed and the clock on the right end of the shed reads $(L_{S,0} - L_L)/v = 9.63\,\text{ns}$. In the reference frame of the ladder the two clocks are moving to the left at speed $v = 0.866c$. In this frame the clock on the right (the trailing clock) is ahead of the clock on the left by $vL_{S,0}/c^2 = 28.9$ ns, so when the clock on the right reads 9.63 ns the one on the left reads –19.3 ns. This means the left end of the ladder is yet to enter the shed when

the right end of the ladder is exiting the shed. This is consistent with the assertion that in the rest frame of the ladder, the ladder is longer than the shed, so the entire ladder is never entirely inside the shed.

Chapter 11
Gravity

Conceptual Problems

1 • [SSM] True or false:

(*a*) For Kepler's law of equal areas to be valid, the force of gravity must vary inversely with the square of the distance between a given planet and the Sun.
(*b*) The planet closest to the Sun has the shortest orbital period.
(*c*) Venus's orbital speed is larger than the orbital speed of Earth.
(*d*) The orbital period of a planet allows accurate determination of that planet's mass.

(*a*) False. Kepler's law of equal areas is a consequence of the fact that the gravitational force acts along the line joining two bodies but is independent of the manner in which the force varies with distance.

(*b*) True. The periods of the planets vary with the three-halves power of their distances from the Sun. So the shorter the distance from the Sun, the shorter the period of the planet's motion.

(*c*) True. Setting up a proportion involving the orbital speeds of the two planets in terms of their orbital periods and mean distances from the Sun (see Table 11-1) shows that $v_{\text{Venus}} = 1.17 v_{\text{Earth}}$.

(*d*) False. The orbital period of a planet is independent of the planet's mass.

2 • If the mass of a small Earth-orbiting satellite is doubled, the radius of its orbit can remain constant if the speed of the satellite (*a*) increases by a factor of 8, (*b*) increases by a factor of 2, (*c*) does not change, (*d*) is reduced by a factor of 8, (*e*) is reduced by a factor of 2.

Determine the Concept We can apply Newton's second law and the law of gravity to the satellite to obtain an expression for its speed as a function of the radius of its orbit.

Apply Newton's second law to the satellite to obtain:

$$\sum F_{\text{radial}} = \frac{GMm}{r^2} = m\frac{v^2}{r}$$

where M is the mass of the object the satellite is orbiting and m is the mass of the satellite.

Solving for v yields:

$$v = \sqrt{\frac{GM}{r}}$$

Thus the speed of the satellite is independent of its mass and $\boxed{(c)}$ is correct.

3 • **[SSM]** During what season in the northern hemisphere does Earth attain its maximum orbital speed about the Sun? What season is related to its minimum orbital speed? *Hint: Earth is at perihelion in early January.*

Determine the Concept Earth is closest to the Sun during winter in the northern hemisphere. This is the time of fastest orbital speed. Summer would be the time for minimum orbital speed.

4 • Haley's comet is in a highly elliptical orbit about the Sun with a period of about 76 y. Its last closest approach to the Sun occurred in 1987. In what years of the twentieth century was it traveling at its fastest or slowest orbital speed about the Sun?

Determine the Concept Haley's comet was traveling at its fastest orbital speed in 1987, and at its slowest orbital speed 38 years previously in 1949.

5 • Venus has no natural satellites. However artificial satellites have been placed in orbit around it. To use one of their orbits to determine the mass of Venus, what orbital parameters would you have to measure? How would you then use them to do the mass calculation?

Determine the Concept To obtain the mass M of Venus you need to measure the period T and semi-major axis a of the orbit of one of the satellites, substitute the measured values into $\frac{T^2}{a^3} = \frac{4\pi^2}{GM}$ (Kepler's third law), and solve for M.

6 • A majority of the asteroids are in approximately circular orbits in a ″belt″ between Mars and Jupiter. Do they all have the same orbital period about the Sun? Explain.

Determine the Concept No. As described by Kepler's third law, the asteroids closer to the Sun have a shorter ″year″ and are orbiting faster.

7 • **[SSM]** At the surface of the moon, the acceleration due to the gravity of the moon is a. At a distance from the center of the moon equal to four times the radius of the moon, the acceleration due to the gravity of the moon is (*a*) $16a$, (*b*) $a/4$, (*c*) $a/3$, (*d*) $a/16$, (*e*) None of the above.

Picture the Problem The acceleration due to gravity varies inversely with the square of the distance from the center of the moon.

Express the dependence of the acceleration due to the gravity of the moon on the distance from its center:

$$a' \propto \frac{1}{r^2}$$

Express the dependence of the acceleration due to the gravity of the moon at its surface on its radius:

$$a \propto \frac{1}{R_M^2}$$

Divide the first of these expressions by the second to obtain:

$$\frac{a'}{a} = \frac{R_M^2}{r^2}$$

Solving for a' and simplifying yields:

$$a' = \frac{R_M^2}{r^2}a = \frac{R_M^2}{(4R_M)^2}a = \tfrac{1}{16}a$$

and $\boxed{(d)}$ is correct.

8 • At a depth equal to half the radius of Earth, the acceleration due to gravity is about (*a*) *g* (*b*) 2*g* (*c*) *g*/2, (*d*) *g*/4, (*e*) *g*/8, (*f*) You cannot determine the answer based on the data given.

Picture the Problem We can use Newton's law of gravity and the assumption of uniform density to express the ratio of the acceleration due to gravity at a depth equal to half the radius of Earth to the acceleration due to gravity at the surface of Earth.

The acceleration due to gravity at a depth equal to half the radius of Earth is given by:

$$g_{\frac{1}{2}r} = \frac{GM'}{\left(\frac{1}{2}r\right)^2} = \frac{4GM'}{r^2}$$

where M' is the mass of Earth between the location of interest and the center of Earth.

The acceleration due to gravity at the surface of Earth is given by:

$$g = \frac{GM}{r^2}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{g_{\frac{1}{2}r}}{g} = \frac{\frac{4GM'}{r^2}}{\frac{GM}{r^2}} = \frac{4M'}{M} \qquad (1)$$

Express M' in terms of the average density of Earth ρ and the volume V' of Earth between the location of interest and the center of Earth:

$$M' = \rho V' = \rho\left[\tfrac{4}{3}\pi\left(\tfrac{1}{2}r\right)^3\right] = \tfrac{1}{6}\pi\rho r^3$$

Express M in terms of the average density of Earth ρ and the volume V of Earth:

$$M = \rho V = \rho\left(\tfrac{4}{3}\pi r^3\right) = \tfrac{4}{3}\pi\rho r^3$$

Substitute for M and M' in equation (1) and simplify to obtain:

$$\frac{g_{\frac{1}{2}r}}{g} = \frac{4\left(\frac{1}{6}\pi\rho r^3\right)}{\frac{4}{3}\pi\rho r^3} = \frac{1}{2}$$

and $\boxed{(c)}$ is correct.

9 •• Two stars orbit their common center of mass as a *binary* star system. If each of their masses were doubled, what would have to happen to the distance between them in order to maintain the same gravitational force? The distance would have to (*a*) remain the same (*b*) double (*c*) quadruple (*d*) be reduced by a factor of 2 (*e*) You cannot determine the answer based on the data given.

Picture the Problem We can use Newton's law of gravity to express the ratio of the forces and then solve this proportion for the separation of the stars that would maintain the same gravitational force.

The gravitational force acting on the stars before their masses are doubled is given by:

$$F_g = \frac{GmM}{r^2}$$

The gravitational force acting on the stars after their masses are doubled is given by:

$$F_g' = \frac{G(2m)(2M)}{r'^2} = \frac{4GmM}{r'^2}$$

Dividing the second of these equations by the first yields:

$$\frac{F_g'}{F_g} = 1 = \frac{\dfrac{4GmM}{r'^2}}{\dfrac{GmM}{r^2}} = \frac{4r^2}{r'^2}$$

Solving for r' yields:

$r' = 2r$ and $\boxed{(b)}$ is correct.

10 •• If you had been working for NASA in the 1960's and planning the trip to the moon, you would have determined that there exists a unique location somewhere between Earth and the moon, where a spaceship is, for an instant, truly weightless. [Consider only the moon, Earth and the Apollo spaceship, and

neglect other gravitational forces.] Explain this phenomenon and explain whether this location is closer to the moon, midway on the trip, or closer to Earth.

Determine the Concept Between Earth and the moon, the gravitational pulls on the spaceship are oppositely directed. Because of the moon's relatively small mass compared to the mass of Earth, the location where the gravitational forces cancel (thus producing no net gravitational force, a weightless condition) is considerably closer to the moon.

11 •• [SSM] Suppose the escape speed from a planet was only slightly larger than the escape speed from Earth, yet the planet is considerably larger than Earth. How would the planet's (average) density compare to Earth's (average) density? (*a*) It must be denser. (*b*) It must be less dense. (*c*) It must be the same density. (*d*) You cannot determine the answer based on the data given.

Picture the Problem The densities of the planets are related to the escape speeds from their surfaces through $v_e = \sqrt{2GM/R}$.

The escape speed from the planet is given by:

$$v_{\text{planet}} = \sqrt{\frac{2GM_{\text{planet}}}{R_{\text{planet}}}}$$

The escape speed from Earth is given by:

$$v_{\text{Earth}} = \sqrt{\frac{2GM_{\text{Earth}}}{R_{\text{Earth}}}}$$

Expressing the ratio of the escape speed from the planet to the escape speed from Earth and simplifying yields:

$$\frac{v_{\text{planet}}}{v_{\text{Earth}}} = \frac{\sqrt{\dfrac{2GM_{\text{planet}}}{R_{\text{planet}}}}}{\sqrt{\dfrac{2GM_{\text{Earth}}}{R_{\text{Earth}}}}} = \sqrt{\frac{R_{\text{Earth}}}{R_{\text{planet}}}\frac{M_{\text{planet}}}{M_{\text{Earth}}}}$$

Because $v_{\text{planet}} \approx v_{\text{Earth}}$:

$$1 \approx \sqrt{\frac{R_{\text{Earth}}}{R_{\text{planet}}}\frac{M_{\text{planet}}}{M_{\text{Earth}}}}$$

Squaring both sides of the equation yields:

$$1 \approx \frac{R_{\text{Earth}}}{R_{\text{planet}}}\frac{M_{\text{planet}}}{M_{\text{Earth}}}$$

Express M_{planet} and M_{Earth} in terms of their densities and simplify to obtain:

$$1 \approx \frac{R_{\text{Earth}}}{R_{\text{planet}}}\frac{\rho_{\text{planet}}V_{\text{planet}}}{\rho_{\text{Earth}}V_{\text{Earth}}} = \frac{R_{\text{Earth}}}{R_{\text{planet}}}\frac{\rho_{\text{planet}}V_{\text{planet}}}{\rho_{\text{Earth}}V_{\text{Earth}}} = \frac{R_{\text{Earth}}}{R_{\text{planet}}}\frac{\rho_{\text{planet}}\,\frac{4}{3}\pi R_{\text{planet}}^3}{\rho_{\text{Earth}}\,\frac{4}{3}\pi R_{\text{Earth}}^3} = \frac{\rho_{\text{planet}}R_{\text{planet}}^2}{\rho_{\text{Earth}}R_{\text{Earth}}^2}$$

Solving for the ratio of the densities yields:

$$\frac{\rho_{\text{planet}}}{\rho_{\text{Earth}}} \approx \frac{R_{\text{Earth}}^2}{R_{\text{planet}}^2}$$

Because the planet is considerably larger than Earth:

$$\frac{\rho_{\text{planet}}}{\rho_{\text{Earth}}} << 1$$

and $\boxed{(b)}$ is correct.

12 •• Suppose that, using a telescope in your backyard, you discovered a distant object approaching the Sun, and were able to determine both its distance from the Sun and its speed. How would you be able to predict whether the object will remain "bound" to the Solar System, or if it is an interstellar interloper and would come in, turn around and escape, never to return?

Determine the Concept You could take careful measurements of its position as a function of time in order to determine whether its trajectory is an ellipse, a hyperbola, or a parabola. If the path is an ellipse, it will return; if its path is hyperbolic or parabolic, it will not return. Alternatively, by measuring its distance from the Sun, you can estimate the gravitational potential energy (per kg of its mass, and neglecting the planets) of the object, and by determining its position on several successive nights, the speed of the object can be determined. From this, its kinetic energy (per kg) can be determined. The sum of these two gives the comet's total energy (per kg) and if it is positive, it will likely swing once around the Sun and then leave the Solar System forever.

13 •• **[SSM]** Near the end of their useful lives, several large Earth-orbiting satellites have been maneuvered so they burn up as they enter Earth's atmosphere. These maneuvers have to be done carefully so large fragments do not impact populated land areas. You are in charge of such a project. Assuming the satellite of interest has on-board propulsion, in what direction would you fire the rockets for a short burn time to start this downward spiral? What would happen to the kinetic energy, gravitational potential energy and total mechanical energy following the burn as the satellite came closer and closer to Earth?

Determine the Concept You should fire the rocket in a direction to oppose the orbital motion of the satellite. As the satellite gets closer to Earth after the burn, the potential energy will decrease. However, the total mechanical energy will decrease due to the frictional drag forces transforming mechanical energy into thermal energy. The kinetic energy will increase until the satellite enters the atmosphere where the drag forces slow its motion.

14 •• During a trip back from the moon, the Apollo spacecraft fires its rockets to leave its lunar orbit. Then it coasts back to Earth where it enters the atmosphere at high speed, survives a blazing re-entry and parachutes safely into the ocean. In what direction do you fire the rockets to initiate this return trip? Explain the changes in kinetic energy, gravitational potential and total mechanical energy that occur to the spacecraft from the beginning to the end of this journey.

Determine the Concept Near the moon you would fire the rockets to accelerate the spacecraft with the thrust acting in the direction of your ship's velocity at the time. When the rockets have shut down, as you leave the moon, your kinetic energy will initially decrease (the moon's gravitational pull exceeds that of Earth), and your potential energy will increase. After a certain point, Earth's gravitational attraction would begin accelerating the ship and the kinetic energy would increase at the expense of the gravitational potential energy of the spacecraft-Earth-moon system. The spacecraft will enter Earth's atmosphere with its maximum kinetic energy. Eventually, landing in the ocean, the kinetic energy would be zero, the gravitational potential energy a minimum, and the total mechanical energy of the ship will have been dramatically reduced due to air drag forces producing heat and light during re-entry.

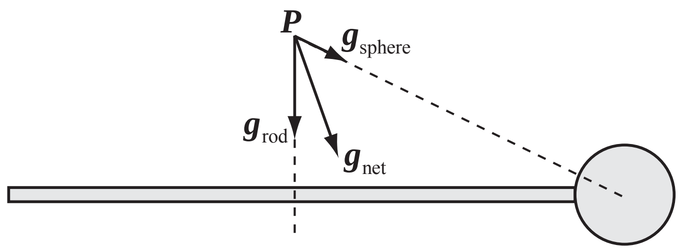
15 •• Explain why the gravitational field inside a solid sphere of uniform mass is directly proportional to r rather than inversely proportional to r.

Determine the Concept At a point inside the sphere a distance r from its center, the gravitational field strength is directly proportional to the amount of mass within a distance r from the center, and inversely proportional to the square of the distance r from the center. The mass within a distance r from the center is proportional to the cube of r. Thus, the gravitational field strength is directly proportional to r.

16 •• In the movie *2001: A Space Odyssey*, a spaceship containing two astronauts is on a long-term mission to Jupiter. A model of their ship could be a uniform pencil-like rod (containing the propulsion systems) with a uniform sphere (the crew habitat and flight deck) attached to one end (Figure 11-23). The design is such that the radius of the sphere is much smaller than the length of the rod. At a location a few meters away from the ship, at point P on the perpendicular bisector of the rod-like section, what would be the direction of the gravitational field due to the ship alone (that is, assuming all other gravitational fields are

negligible)? Explain your answer. At a large distance from the ship, what would be the dependence of its gravitational field on the distance from the ship?

Determine the Concept The pictorial representation shows the point of interest P and the gravitational fields $\vec{g}_{\text{rod}}$ and $\vec{g}_{\text{sphere}}$ due to the rod and the sphere as well as the resultant field $\vec{g}_{\text{net}}$. Note that the net field (the sum of $\vec{g}_{\text{rod}}$ and $\vec{g}_{\text{sphere}}$) points slightly toward the habitat end of the ship. At very large distances, the rod+sphere mass distribution looks like a point mass, so the field's distance dependence is an inverse square dependence.



Estimation and Approximation

17 • **[SSM]** Estimate the mass of our galaxy (the Milky Way) if the Sun orbits the center of the galaxy with a period of 250 million years at a mean distance of 30,000 $c\cdot$y. Express the mass in terms of multiples of the solar mass M_S. (Neglect the mass farther from the center than the Sun, and assume that the mass closer to the center than the Sun exerts the same force on the Sun as would a point particle of the same mass located at the center of the galaxy.)

Picture the Problem To approximate the mass of the galaxy we'll assume the galactic center to be a point mass with the Sun in orbit about it and apply Kepler's third law. Let M_G represent the mass of the galaxy.

Using Kepler's third law, relate the period of the Sun T to its mean distance R_0 from the center of the galaxy:

$$T^2 = \frac{4\pi^2}{GM_G}R_0^3 \Rightarrow \frac{M_G}{M_S} = \frac{4\pi^2 R_0^3}{GM_S T^2}$$

Substitute numerical values and evaluate M_G/M_s:

$$\frac{M_G}{M_s} = \frac{4\pi^2\left(3.00\times10^4\ c\cdot\text{y}\times\dfrac{9.461\times10^{15}\ \text{m}}{c\cdot\text{y}}\right)^3}{\left(6.6742\times10^{-11}\ \dfrac{\text{N}\cdot\text{m}^2}{\text{kg}^2}\right)\left(1.99\times10^{30}\ \text{kg}\right)\left(250\times10^6\ \text{y}\times3.156\times10^7\ \dfrac{\text{s}}{\text{y}}\right)^2}$$

$$\approx 1.1\times10^{11} \Rightarrow M_{\text{galaxy}} \approx \boxed{1.1\times10^{11} M_s}$$

18 •• Besides studying samples of the lunar surface, the Apollo astronauts had several ways of determining that the moon is *not* made of green cheese. Among these ways are measurements of the gravitational acceleration at the lunar surface. Estimate the gravitational acceleration at the lunar surface if the moon were, in fact, a solid block of green cheese and compare it to the known value of the gravitational acceleration at the lunar surface.

Picture the Problem The density of a planet or other object determines the strength of the gravitational force it exerts on other objects. We can use Newton's law of gravity to express the acceleration due to gravity at the surface of the moon as a function of the density of the moon. Estimating the density of cheese will then allow us to calculate what the acceleration due to gravity at the surface of the moon would be if the moon were made of cheese. Finally, we can compare this value to the measured value of 1.62 m/s^2.

Apply Newton's law of gravity to an object of mass m at the surface of the moon to obtain:

$$F_g = ma_g = \frac{GmM}{r_{moon}^2} \Rightarrow a_g = \frac{GM}{r_{moon}^2}$$

Assuming the moon to be made of cheese, substitute for its mass to obtain:

$$a_{g,cheese} = \frac{G\rho_{cheese}V_{moon}}{r_{moon}^2}$$

Substituting for the volume of the moon and simplifying yields:

$$a_{g,cheese} = \frac{G\rho_{cheese}\frac{4}{3}\pi r_{moon}^3}{r_{moon}^2} = \frac{4\pi}{3}G\rho_{cheese}r_{moon}$$

Substitute numerical values and evaluate a_g:

$$a_{g,cheese} = \frac{4\pi}{3}\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(0.80\frac{\text{g}}{\text{cm}^3}\times\frac{1\ \text{kg}}{10^3\ \text{g}}\times\frac{10^6\ \text{cm}^3}{\text{m}^3}\right)\left(1.738\times10^6\ \text{m}\right) = \boxed{0.39\ \text{m/s}^2}$$

Express the ratio of $a_{g,cheese}$ to the measured value of $a_{g,moon}$:

$$\frac{a_{g,cheese}}{a_{g,moon}} = \frac{0.388\ \text{m/s}^2}{1.62\ \text{m/s}^2} = 0.24$$

or

$$a_{g,cheese} \approx \boxed{0.24a_{g,moon}}$$

19 •• You are in charge of the first manned exploration of an asteroid. You are concerned that, due to the weak gravitational field and resulting low escape speed, tethers might be required to bind the explorers to the surface of the

asteroid. Therefore, if you do not wish to use tethers, you have to be careful about which asteroids to choose to explore. Estimate the largest radius the asteroid can have that would still allow you to escape its surface by jumping. Assume spherical geometry and reasonable rock density.

Picture the Problem The density of an asteroid determines the strength of the gravitational force it exerts on other objects. We can use the equation for the escape speed from an asteroid of mass M_{asteroid} and radius R_{asteroid} to derive an expression for the radius of an asteroid as a function of its escape speed and density. We can approximate the escape speed from the asteroid by determining one's push-off speed for a jump at the surface of Earth.

The escape speed from an asteroid is given by:

$$v_{\text{e,asteroid}} = \sqrt{\frac{2GM_{\text{asteroid}}}{R_{\text{asteroid}}}}$$

In terms of the density of the asteroid, $v_{\text{e,asteroid}}$ becomes:

$$v_{\text{e,asteroid}} = \sqrt{\frac{2G\rho_{\text{asteroid}}\frac{4}{3}\pi R_{\text{asteroid}}^3}{R_{\text{asteroid}}}} = \sqrt{\tfrac{8}{3}\pi G\rho_{\text{asteroid}}}\,R_{\text{asteroid}}$$

Solving for R_{asteroid} yields:

$$R_{\text{asteroid}} = \frac{v_{\text{e,asteroid}}}{\sqrt{\frac{8}{3}\pi G\rho_{\text{asteroid}}}} \qquad (1)$$

Using a constant-acceleration equation, relate the height h to which you can jump on the surface of Earth to your push-off speed:

$$v^2 = v_0^2 - 2gh$$

or, because $v = 0$,

$$0 = v_0^2 - 2gh \Rightarrow v_0 = \sqrt{2gh}$$

Letting $v_0 = v_{\text{e,asteroid}}$, substitute in equation (1) and simplify to obtain:

$$R_{\text{asteroid}} = \frac{\sqrt{2gh}}{\sqrt{\frac{8}{3}\pi G\rho_{\text{asteroid}}}} = \sqrt{\frac{3gh}{4\pi G\rho_{\text{asteroid}}}}$$

Assuming that you can jump 0.75 m and that the average density of an asteroid is 3.0 g/cm^3, substitute numerical values and evaluate R_{asteroid}:

$$R_{\text{asteroid}} = \sqrt{\frac{3\left(9.81\ \text{m/s}^2\right)(0.75\ \text{m})}{4\pi\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(3.0\frac{\text{g}}{\text{cm}^3}\times\frac{1\ \text{kg}}{10^3\ \text{g}}\times\frac{10^6\ \text{cm}^3}{\text{m}^3}\right)}} \approx \boxed{3.0\ \text{km}}$$

20 ••• One of the great discoveries in astronomy in the past decade is the detection of planets outside the Solar System. Since 1996, more than 100 planets have been detected orbiting stars other than the Sun. While the planets themselves cannot be seen directly, telescopes can detect the small periodic motion of the star

as the star and planet orbit around their common center of mass. (This is measured using the *Doppler effect*, which is discussed in Chapter 15.) Both the period of this motion and the variation in the speed of the star over the course of time can be determined observationally. The mass of the star is found from its observed luminance and from the theory of stellar structure. *Iota Draconis* is the 8th brightest star in the constellation Draco. Observations show that a planet, with an orbital period of 1.50 y, is orbiting this star. The mass of Iota Draconis is $1.05M_{\text{Sun}}$. (*a*) Estimate the size (in AU) of the semimajor axis of this planet's orbit. (*b*) The radial speed of the star is observed to vary by 592 m/s. Use conservation of momentum to find the mass of the planet. Assume the orbit is circular, we are observing the orbit edge-on, and no other planets orbit Iota Draconis. Express the mass as a multiple of the mass of Jupiter.

Picture the Problem We can use Kepler's third law to find the size of the semi-major axis of the planet's orbit and the conservation of momentum to find its mass.

(*a*) Using Kepler's third law, relate the period of this planet T to the length r of its semi-major axis and simplify to obtain:

$$T^2 = \frac{4\pi^2}{GM_{\text{Iota Draconis}}}r^3 = \frac{\dfrac{4\pi^2}{M_{\text{s}}}}{G\dfrac{M_{\text{Iota Draconis}}}{M_{\text{s}}}}r^3 = \frac{\dfrac{4\pi^2}{GM_{\text{s}}}}{\dfrac{M_{\text{Iota Draconis}}}{M_{\text{s}}}}r^3$$

If we measure time in years, distances in AU, and masses in terms of the mass of the sun:

$$\frac{4\pi^2}{MG_{\text{s}}} = 1 \text{ and } T^2 = \frac{1}{\dfrac{M_{\text{Iota Draconis}}}{M_{\text{s}}}}r^3$$

Solving for r yields:

$$r = \sqrt[3]{\frac{M_{\text{Iota Draconis}}}{M_{\text{s}}}T^2}$$

Substitute numerical values and evaluate r:

$$r = \sqrt[3]{\left(\frac{1.05\,M_{\text{s}}}{M_{\text{s}}}\right)(1.50\,\text{y})^2} = \boxed{1.33\,\text{AU}}$$

(*b*) Apply conservation of momentum to the planet (mass m and speed v) and the star (mass $M_{\text{Iota Draconis}}$ and speed V) to obtain:

$$mv = M_{\text{Iota Draconis}}V$$

Solve for m to obtain:

$$m = M_{\text{Iota Draconis}}\frac{V}{v} \qquad (1)$$

The speed v of the orbiting planet is given by:

$$v = \frac{\Delta d}{\Delta t} = \frac{2\pi r}{T}$$

Substitute numerical values and evaluate v:

$$v = \frac{2\pi\left(1.33\,\text{AU}\times\frac{1.50\times10^{11}\,\text{m}}{\text{AU}}\right)}{1.50\,\text{y}\times\frac{365.24\,\text{d}}{\text{y}}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\,\text{s}}{\text{h}}} = 2.648\times10^{4}\,\text{m/s}$$

Substitute numerical values in equation (1) and evaluate m:

$$m = (1.05M_{\text{sun}})\left(\frac{296\,\text{m/s}}{2.648\times10^{4}\,\text{m/s}}\right) = (1.05)(1.99\times10^{30}\,\text{kg})(0.0112) = 2.336\times10^{28}\,\text{kg}$$

Express m as a fraction of the mass M_{J} of Jupiter:

$$\frac{m}{M_{\text{J}}} = \frac{2.336\times10^{28}\,\text{kg}}{1.90\times10^{27}\,\text{kg}} = 12.3$$

or

$$m = \boxed{12.3M_{\text{J}}}$$

Remarks: A more sophisticated analysis, using the eccentricity of the orbit, leads to a lower bound of 8.7 Jovian masses. (Only a lower bound can be established, as the plane of the orbit is not known.)

21 ••• One of the biggest unresolved problems in the theory of the formation of the solar system is that, while the mass of the Sun is 99.9 percent of the total mass of the Solar System, it carries only about 2 percent of the total angular momentum. The most widely accepted theory of solar system formation has as its central hypothesis the collapse of a cloud of dust and gas under the force of gravity, with most of the mass forming the Sun. However, because the net angular momentum of this cloud is conserved, a simple theory would indicate that the Sun should be rotating much more rapidly than it currently is. In this problem, you will show why it is important that most of the angular momentum was somehow transferred to the planets. (*a*) The Sun is a cloud of gas held together by the force of gravity. If the Sun were rotating too rapidly, gravity couldn't hold it together. Using the known mass of the Sun (1.99×10^{30} kg) and its radius (6.96×10^{8} m), estimate the maximum angular speed that the Sun can have if it is to stay intact. What is the period of rotation corresponding to this rotation rate? (*b*) Calculate the orbital angular momentum of Jupiter and of Saturn from their masses (318 and 95.1 Earth masses, respectively), mean distances from the Sun (778 and 1430 million km, respectively), and orbital periods (11.9 and 29.5 y, respectively). Compare them to the experimentally measured value of the Sun's angular momentum of 1.91×10^{41} kg·m^2/s. (*c*) If we were to somehow transfer all of

Jupiter's and Saturn's angular momentum to the Sun, what would be the Sun's new rotational period? The Sun is not a uniform sphere of gas, and its moment of inertia is given by the formula $I = 0.059MR^2$. Compare this to the maximum rotational period of Part (*a*).

Picture the Problem We can apply Newton's law of gravity to estimate the maximum angular speed that the Sun can have if it is to stay together and use the definition of angular momentum to find the orbital angular momenta of Jupiter and Saturn. In Part (*c*) we can relate the final angular speed of the Sun to its initial angular speed, its moment of inertia, and the orbital angular momenta of Jupiter and Saturn.

(*a*) Gravity must supply the centripetal force which keeps an element of the sun's mass *m* rotating around it. Letting R_S represent the radius of the Sun and M_S the mass of the Sun, apply Newton's law of gravity to an object of mass *m* on the surface of the Sun to obtain:

$$m\omega^2 R_S < \frac{GM_S m}{R_S^2}$$

or

$$\omega^2 R_S < \frac{GM_S}{R_S^2} \Rightarrow \omega < \sqrt{\frac{GM_S}{R_S^3}}$$

where we've used the inequality because we're estimating the *maximum* angular speed which the sun can have if it is to stay together.

Substitute numerical values and evaluate ω:

$$\omega < \sqrt{\frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\ \text{kg})}{(6.96\times10^{8}\ \text{m})^3}} = \boxed{6.28\times10^{-4}\ \text{rad/s}}$$

Calculate the maximum period of this motion from its angular speed:

$$T_{\max} = \frac{2\pi}{\omega} = \frac{2\pi}{6.28\times10^{-4}\ \text{rad/s}}$$
$$= 1.00\times10^{4}\ \text{s}\times\frac{1\ \text{h}}{3600\ \text{s}} = \boxed{2.78\ \text{h}}$$

(*b*) Express the orbital angular momenta of Jupiter and Saturn:

$$L_J = m_J r_J v_J \text{ and } L_S = m_S r_S v_S$$

Express the orbital speeds of Jupiter and Saturn in terms of their periods and distances from the sun:

$$v_J = \frac{2\pi r_J}{T_J} \text{ and } v_S = \frac{2\pi r_S}{T_S}$$

Substitute to obtain:

$$L_J = \frac{2\pi m_J r_J^2}{T_J} \text{ and } L_S = \frac{2\pi m_S r_S^2}{T_S}$$

Substitute numerical values and evaluate L_J and L_S:

$$L_J = \frac{2\pi(318M_E)r_J^2}{T_J} = \frac{2\pi(318)(5.98\times10^{24}\text{ kg})(778\times10^9\text{ m})^2}{11.9\text{ y}\times\frac{365.24\text{ d}}{\text{y}}\times\frac{24\text{ h}}{\text{d}}\times\frac{3600\text{ s}}{\text{h}}}$$
$$= \boxed{1.93\times10^{43}\text{ kg}\cdot\text{m}^2/\text{s}}$$

and

$$L_S = \frac{2\pi(95.1M_E)r_S^2}{T_S} = \frac{2\pi(95.1)(5.98\times10^{24}\text{ kg})(1430\times10^9\text{ m})^2}{29.5\text{ y}\times\frac{365.24\text{ d}}{\text{y}}\times\frac{24\text{ h}}{\text{d}}\times\frac{3600\text{ s}}{\text{h}}}$$
$$= \boxed{7.85\times10^{42}\text{ kg}\cdot\text{m}^2/\text{s}}$$

Express the angular momentum of the Sun as a fraction of the sum of the angular momenta of Jupiter and Saturn:

$$\frac{L_{\text{sun}}}{L_J + L_S} = \frac{1.91\times10^{41}\text{ kg}\cdot\text{m}^2/\text{s}}{(19.3+7.85)\times10^{42}\text{ kg}\cdot\text{m}^2/\text{s}} = \boxed{0.70\%}$$

(*c*) The Sun's rotational period depends on its rotational speed:

$$T_{\text{Sun}} = \frac{2\pi}{\omega_f} \qquad (1)$$

Relate the final angular momentum of the sun to its initial angular momentum and the angular momenta of Jupiter and Saturn:

$$L_f = L_i + L_J + L_S$$
or
$$I_{\text{Sun}}\omega_f = I_{\text{Sun}}\omega_i + L_J + L_S$$

Solve for ω_f to obtain:

$$\omega_f = \omega_i + \frac{L_J + L_S}{I_{\text{sun}}}$$

Substitute for ω_i and I_{Sun}:

$$\omega_f = \frac{2\pi}{T_{\text{Sun}}} + \frac{L_J + L_S}{0.059M_{\text{sun}}R_{\text{sun}}^2}$$

Substitute numerical values and evaluate ω_f:

$$\omega_f = \frac{2\pi}{30\text{ d}\times\frac{24\text{ h}}{\text{d}}\times\frac{3600\text{ s}}{\text{h}}} + \frac{(19.3+7.85)\times10^{42}\text{ kg}\cdot\text{m}^2/\text{s}}{0.059(1.99\times10^{30}\text{ kg})(6.96\times10^8\text{ m})^2}$$
$$= 4.798\times10^{-4}\text{ rad/s}$$

Substitute numerical values in equation (1) and evaluate T_{Sun}:

$$T_{Sun} = \frac{2\pi}{4.798\times10^{-4}\,\frac{\text{rad}}{\text{s}}\times\frac{3600\,\text{s}}{\text{h}}} = \boxed{3.64\,\text{h}}$$

Compare this to the maximum rotational period of Part (*a*).

$$\frac{T_{Sun}}{T_{max}} = \frac{3.64\,\text{h}}{2.78\,\text{h}} = 1.31$$

or

$$T_{Sun} = \boxed{1.31T_{max}}$$

Kepler's Laws

22 • The new comet Alex-Casey has a very elliptical orbit with a period of 127.4 y. If the closest approach of Alex-Casey to the Sun is 0.1 AU, what is its greatest distance from the Sun?

Picture the Problem We can use the relationship between the semi-major axis and the distances of closest approach and greatest separation, together with Kepler's third law, to find the greatest separation of Alex-Casey from the Sun.

Letting x represent the greatest distance from the Sun, express the relationship between x, the distance of closest approach, and its semi-major axis R:

$$R = \frac{x + 0.1\,\text{AU}}{2} \Rightarrow x = 2R - 0.1\,\text{AU} \quad (1)$$

Apply Kepler's third law, with the period T measured in years and R in AU to obtain:

$$T^2 = R^3 \Rightarrow R = \sqrt[3]{T^2}$$

Substituting for R in equation (1) yields:

$$x = 2\sqrt[3]{T^2} - 0.1\,\text{AU}$$

Substitute numerical values and evaluate x:

$$x = 2\sqrt[3]{(127.4\,\text{y})^2} - 0.1\,\text{AU} = \boxed{50.5\,\text{AU}}$$

23 • The radius of Earth's orbit is 1.496×10^{11} m and that of Uranus is 2.87×10^{12} m. What is the orbital period of Uranus?

Picture the Problem We can use Kepler's third law to relate the orbital period of Uranus to the orbital period of Earth.

Using Kepler's third law, relate the orbital period of Uranus to its mean distance from the Sun:

$$T_{\text{Uranus}}^2 = \frac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Uranus}}^3$$

.

Using Kepler's third law, relate the orbital period of Earth to its mean distance from the Sun:

$$T_{\text{Earth}}^2 = \frac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Earth}}^3$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{T_{\text{Uranus}}^2}{T_{\text{Earth}}^2} = \frac{\dfrac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Uranus}}^3}{\dfrac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Earth}}^3} = \frac{r_{\text{Uranus}}^3}{r_{\text{Earth}}^3}$$

Solve for T_{Uranus} to obtain:

$$T_{\text{Uranus}} = T_{\text{Earth}} \left(\frac{r_{\text{Uranus}}}{r_{\text{Earth}}} \right)^{3/2}$$

Substitute numerical values and evaluate T_{Uranus}:

$$T_{\text{Uranus}} = (1.00\ \text{y}) \left(\frac{2.87 \times 10^{12}\ \text{m}}{1.496 \times 10^{11}\ \text{m}} \right)^{3/2} = \boxed{84.0\ \text{y}}$$

24 • The asteroid Hektor, discovered in 1907, is in a nearly circular orbit of radius 5.16 *AU* about the Sun. Determine the period of this asteroid.

Picture the Problem We can use Kepler's third law to relate the orbital period of Hector to the orbital period of Earth.

Using Kepler's third law, relate the orbital period of Hektor to its mean distance from the Sun:

$$T_{\text{Hector}}^2 = \frac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Hector}}^3$$

Using Kepler's third law, relate the orbital period of Earth to its mean distance from the Sun:

$$T_{\text{Earth}}^2 = \frac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Earth}}^3$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{T_{\text{Hector}}^2}{T_{\text{Earth}}^2} = \frac{\dfrac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Hector}}^3}{\dfrac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Earth}}^3} = \frac{r_{\text{Hector}}^3}{r_{\text{Earth}}^3}$$

Solve for T_{Hector} to obtain:

$$T_{\text{Hector}} = T_{\text{Earth}}\left(\frac{r_{\text{Hector}}}{r_{\text{Earth}}}\right)^{3/2}$$

Substitute numerical values and evaluate T_{Hector}:

$$T_{\text{Hector}} = (1.00\ \text{y})\left(\frac{5.16\ \text{AU}}{1.00\ \text{AU}}\right)^{3/2} = \boxed{11.7\ \text{y}}$$

25 •• **[SSM]** One of the so-called "Kirkwood gaps" in the asteroid belt occurs at an orbital radius at which the period of the orbit is half that of Jupiter's. The reason there is a gap for orbits of this radius is because of the periodic pulling (by Jupiter) that an asteroid experiences at the same place in its orbit every *other* orbit around the sun. Repeated tugs from Jupiter of this kind would eventually change the orbit of such an asteroid. Therefore, all asteroids that would otherwise have orbited at this radius have presumably been cleared away from the area due to this resonance phenomenon. How far from the Sun is this particular 2:1 resonance "Kirkwood" gap?

Picture the Problem The period of an orbit is related to its semi-major axis (for circular orbits this distance is the orbital radius). Because we know the orbital periods of Jupiter and a hypothetical asteroid in the Kirkwood gap, we can use Kepler's third law to set up a proportion relating the orbital periods and average distances of Jupiter and the asteroid from the Sun from which we can obtain an expression for the orbital radius of an asteroid in the Kirkwood gap.

Use Kepler's third law to relate Jupiter's orbital period to its mean distance from the Sun:

$$T_{\text{Jupiter}}^2 = \frac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Jupiter}}^3$$

Use Kepler's third law to relate the orbital period of an asteroid in the Kirkwood gap to its mean distance from the Sun:

$$T_{\text{Kirkwood}}^2 = \frac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Kirkwood}}^3$$

Dividing the second of these equations by the first and simplifying yields:

$$\frac{T_{\text{Kirkwood}}^2}{T_{\text{Jupiter}}^2} = \frac{\dfrac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Kirkwood}}^3}{\dfrac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Jupiter}}^3} = \frac{r_{\text{Kirkwood}}^3}{r_{\text{Jupiter}}^3}$$

Solving for r_{Kirkwood} yields:

$$r_{\text{Kirkwood}} = r_{\text{Jupiter}}\left(\frac{T_{\text{Kirkwood}}}{T_{\text{Jupiter}}}\right)^{2/3}$$

Because the period of the orbit of an asteroid in the Kirkwood gap is half that of Jupiter's:

$$r_{\text{Kirkwood}} = \left(77.8\times10^{10}\ \text{m}\right)\left(\frac{\frac{1}{2}T_{\text{Jupiter}}}{T_{\text{Jupiter}}}\right)^{2/3} = \boxed{4.90\times10^{11}\ \text{m}}$$

$$= 4.90\times10^{11}\ \text{m}\times\frac{1\ \text{AU}}{1.50\times10^{11}\text{m}} = \boxed{3.27\ \text{AU}}$$

Remarks: There are also significant Kirkwood gaps at 3:1, 5:2, and 7:3 and resonances at 2.5 AU, 2.82 AU, and 2.95 AU.

26 •• The tiny Saturnian moon, Atlas, is locked into what is known as an orbital resonance with another moon, Mimas, whose orbit lies outside of Atlas's. The ratio between periods of these orbits is 3:2 – that means, for every 3 orbits of Atlas, Mimas completes 2 orbits. Thus, Atlas, Mimas and Saturn are aligned at intervals equal to two orbital periods of Atlas. If Mimas orbits Saturn at a radius of 186,000 km, what is the radius of Atlas's orbit?

Picture the Problem The period of an orbit is related to its semi-major axis (for circular orbits this distance is the orbital radius). Because we know the orbital periods of Atlas and Mimas, we can use Kepler's third law to set up a proportion relating the orbital periods and average distances from Saturn of Atlas and Mimas from which we can obtain an expression for the radius of Atlas's orbit.

Use Kepler's third law to relate Atlas's orbital period to its mean distance from Saturn:

$$T_{\text{Atlas}}^2 = \frac{4\pi^2}{GM_{\text{Saturn}}}r_{\text{Atlas}}^3$$

Use Kepler's third law to relate the orbital period of Mimas to its mean distance from Saturn:

$$T_{\text{Mimas}}^2 = \frac{4\pi^2}{GM_{\text{Saturn}}}r_{\text{Mimas}}^3$$

Dividing the second of these equations by the first and simplifying yields:

$$\frac{T_{\text{Mimas}}^2}{T_{\text{Atlas}}^2} = \frac{\dfrac{4\pi^2}{GM_{\text{Saturn}}}r_{\text{Mimas}}^3}{\dfrac{4\pi^2}{GM_{\text{Saturn}}}r_{\text{Atlas}}^3} = \frac{r_{\text{Mimas}}^3}{r_{\text{Atlas}}^3}$$

Solving for r_{Atlas} yields:

$$r_{\text{Atlas}} = r_{\text{Mimas}}\left(\frac{T_{\text{Atlas}}}{T_{\text{Mimas}}}\right)^{2/3}$$

Because for every 3 orbits of Atlas, Mimas has completed 2:

$$r_{\text{Atlas}} = \left(1.86\times10^{5}\ \text{km}\right)\left(\frac{2}{3}\right)^{2/3} = \boxed{1.42\times10^{5}\ \text{km}}$$

27 •• The asteroid Icarus, discovered in 1949, was so named because its highly eccentric elliptical orbit brings it close to the Sun at perihelion. The eccentricity e of an ellipse is defined by the relation $r_{\text{p}} = a(1 - e)$, where r_{p} is the perihelion distance and a is the semimajor axis. Icarus has an eccentricity of 0.83 and a period of 1.1 y. (*a*) Determine the semimajor axis of the orbit of Icarus. (*b*) Find the perihelion and aphelion distances of the orbit of Icarus.

Picture the Problem Kepler's third law relates the period of Icarus to the length of its semimajor axis. The aphelion distance r_{a} is related to the perihelion distance r_{p} and the semimajor axis by $r_{\text{a}} + r_{\text{p}} = 2a$.

(*a*) Using Kepler's third law, relate the period T of Icarus to the length a of its semimajor axis:

$$T^2 = \frac{4\pi^2}{GM_{\text{Sun}}}a^3 \Rightarrow a = \sqrt[3]{\frac{T^2}{C}}$$

where $C = \dfrac{4\pi^2}{GM_{\text{Sun}}} = 2.973\times10^{-19}\ \text{s}^2/\text{m}^3$.

Substitute numerical values and evaluate a:

$$a = \sqrt[3]{\frac{\left(1.1\text{y}\times\dfrac{365.24\,\text{d}}{\text{y}}\times\dfrac{24\,\text{h}}{\text{d}}\times\dfrac{3600\,\text{s}}{\text{h}}\right)^2}{2.973\times10^{-19}\ \text{s}^2/\text{m}^3}} = \boxed{1.6\times10^{11}\ \text{m}}$$

(*b*) Use the definition of the eccentricity of an ellipse to determine the perihelion distance of Icarus:

$$r_{\text{p}} = a(1-e) = \left(1.59\times10^{11}\ \text{m}\right)(1-0.83) = 2.71\times10^{10}\ \text{m} = \boxed{2.7\times10^{10}\ \text{m}}$$

Express the relationship between r_{p} and r_{a} for an ellipse:

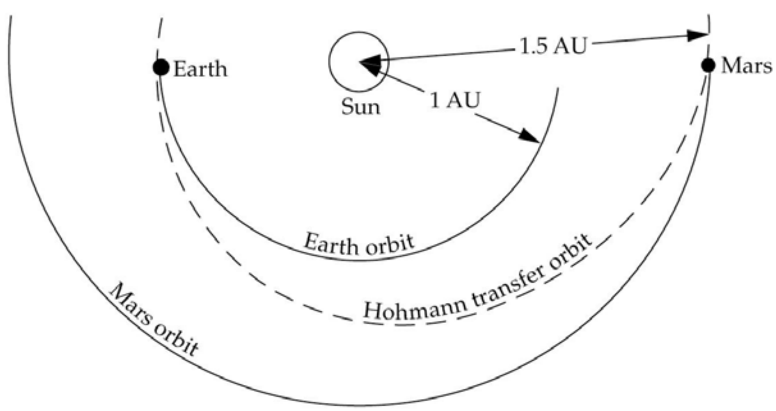
$$r_{\text{a}} + r_{\text{p}} = 2a \Rightarrow r_{\text{a}} = 2a - r_{\text{p}}$$

Substitute numerical values and evaluate r_{a}:

$$r_{\text{a}} = 2\left(1.59\times10^{11}\ \text{m}\right) - 2.71\times10^{10}\ \text{m} = \boxed{2.9\times10^{11}\ \text{m}}$$

28 •• A manned mission to Mars and its attendant problems due to the extremely long time the astronauts would spend weightless and without supplies in space have been extensively discussed. To examine this issue in a simple way, consider one possible trajectory for the spacecraft: the "Hohmann transfer orbit." This orbit consists of an elliptical orbit tangent to the orbit of Earth at its perihelion and tangent to the orbit of Mars at its aphelion. Given that Mars has a mean distance from the Sun of 1.52 times the mean Sun–Earth distance, calculate the time spent by the astronauts during the out-bound part of the trip to Mars. Many adverse biological effects (such as muscle atrophy, decreased bone density, etc.) have been observed in astronauts returning from near-Earth orbit after only a few months in space. As the flight doctor, are there any health issues you should be aware of?

Picture the Problem The Hohmann transfer orbit is shown in the diagram. We can apply Kepler's third law to relate the time-in-orbit to the period of the spacecraft in its Hohmann Earth-to-Mars orbit. The period of this orbit is, in turn, a function of its semi-major axis, which we can find from the average of the lengths of the semi-major axes of Earth and Mars orbits.



Using Kepler's third law, relate the period T of the spacecraft to the semi-major axis of its orbit:

$$T^2 = R^3 \Rightarrow T = \sqrt{R^3}$$
where T is in years and R is in AU.

Relate the out-bound transit time to the period of this orbit:

$$t_{\text{out-bound}} = \tfrac{1}{2}T = \tfrac{1}{2}\sqrt{R^3}$$

Express the semi-major axis of the Hohmann transfer orbit in terms of the mean Sun-Mars and Sun-Earth distances:

$$R = \frac{1.52\,\text{AU} + 1.00\,\text{AU}}{2} = 1.26\,\text{AU}$$

Substitute numerical values and evaluate $t_{\text{out-bound}}$:

$$t_{\text{out-bound}} = \tfrac{1}{2}\sqrt{(1.26\,\text{AU})^3} = 0.707\,\text{y} \times \frac{365.24\,\text{d}}{1\,\text{y}} = \boxed{258\ \text{d}}$$

In order for bones and muscles to maintain their health, they need to be under compression as they are on Earth. Due to the long duration (well over a year) of the round trip, you would want to design an exercise program that would maintain the strength of their bones and muscles.

29 •• [SSM] Kepler determined distances in the Solar System from his data. For example, he found the relative distance from the Sun to Venus (as compared to the distance from the Sun to Earth) as follows. Because Venus's orbit is closer to the Sun than is Earth's orbit, Venus is a morning or evening star—its position in the sky is never very far from the Sun (Figure 11-24). If we suppose the orbit of Venus is a perfect circle, then consider the relative orientation of Venus, Earth, and the Sun at maximum extension, that is when Venus is farthest from the Sun in the sky. (*a*) Under this condition, show that angle *b* in Figure 11-24 is 90º. (*b*) If the maximum elongation angle *a* between Venus and the Sun is 47º, what is the distance between Venus and the Sun in AU? (*c*) Use this result to estimate the length of a Venusian ″year.″

Picture the Problem We can use a property of lines tangent to a circle and radii drawn to the point of contact to show that $b = 90°$. Once we've established that *b* is a right angle we can use the definition of the sine function to relate the distance from the Sun to Venus to the distance from the Sun to Earth.

(*a*) The line from Earth to Venus′ orbit is tangent to the orbit of Venus at the point of maximum extension. Venus will appear farther from the Sun in Earth's sky when it passes the line drawn from Earth that is tangent to its orbit. Hence $b = \boxed{90°}$

(*b*) Using trigonometry, relate the distance from the Sun to Venus d_{SV} to the angle *a*:

$$\sin a = \frac{d_{\text{SV}}}{d_{\text{SE}}} \Rightarrow d_{\text{SV}} = d_{\text{SE}} \sin a$$

Substitute numerical values and evaluate d_{SV}:

$$d_{\text{SV}} = (1.00\,\text{AU})\sin 47° = 0.731\,\text{AU} = \boxed{0.73\,\text{AU}}$$

(*c*) Use Kepler's third law to relate Venus's orbital period to its mean distance from the Sun:

$$T_{\text{Venus}}^2 = \frac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Venus}}^3$$

Use Kepler's third law to relate Earth's orbital period to its mean distance from the Sun:

$$T_{\text{Earth}}^2 = \frac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Earth}}^3$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{T_{\text{Venus}}^2}{T_{\text{Earth}}^2} = \frac{\dfrac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Venus}}^3}{\dfrac{4\pi^2}{GM_{\text{Sun}}} r_{\text{Earth}}^3} = \frac{r_{\text{Venus}}^3}{r_{\text{Earth}}^3}$$

Solving for T_{Venus} yields:

$$T_{\text{Venus}} = T_{\text{Earth}} \left(\frac{r_{\text{Venus}}}{r_{\text{Earth}}} \right)^{3/2}$$

Using the result from Part (*b*) yields:

$$T_{\text{Venus}} = (1.00\ \text{y}) \left(\frac{0.731\ \text{AU}}{1.00\ \text{AU}} \right)^{3/2} = \boxed{0.63\ \text{y}}$$

Remarks: The correct distance from the sun to Venus is closer to 0.723 AU.

30 •• At apogee the center of the moon is 406,395 km from the center of Earth and at perigee the moon is 357,643 km from the center of Earth. What is the orbital speed of the moon at perigee and at apogee? The mass of Earth is 5.98×10^{24} kg.

Picture the Problem Because the gravitational force Earth exerts on the moon is along the line joining their centers, the net torque acting on the moon is zero and its angular momentum is conserved in its orbit about Earth. Because energy is also conserved, we can combine these two expressions to solve for either v_p or v_a initially and then use conservation of angular momentum to find the other.

Letting *m* be the mass of the moon, apply conservation of angular momentum to the moon at apogee and perigee to obtain:

$$mv_p r_p = mv_a r_a \Rightarrow v_a = \frac{r_p}{r_a} v_p \qquad (1)$$

Apply conservation of energy to the moon-Earth system to obtain:

$$\tfrac{1}{2} m v_p^2 - \frac{GMm}{r_p} = \tfrac{1}{2} m v_a^2 - \frac{GMm}{r_a}$$

or

$$\tfrac{1}{2} v_p^2 - \frac{GM}{r_p} = \tfrac{1}{2} v_a^2 - \frac{GM}{r_a}$$

Substitute for v_a to obtain:

$$\tfrac{1}{2}v_p^2 - \frac{GM}{r_p} = \tfrac{1}{2}\left(\frac{r_p}{r_a}v_p\right)^2 - \frac{GM}{r_a}$$
$$= \tfrac{1}{2}\left(\frac{r_p}{r_a}\right)^2 v_p^2 - \frac{GM}{r_a}$$

Solving for v_p yields:

$$v_p = \sqrt{\frac{2GM}{r_p}\left(\frac{1}{1+r_p/r_a}\right)}$$

Substitute numerical values and evaluate v_p:

$$v_p = \sqrt{\frac{2\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(5.98\times10^{24}\ \text{kg}\right)}{3.576\times10^{8}\ \text{m}}\left(\frac{1}{1+\dfrac{3.576\times10^{8}\ \text{m}}{4.064\times10^{8}\ \text{m}}}\right)} = \boxed{1.09\ \text{km/s}}$$

Substitute numerical values in equation (1) and evaluate v_a:

$$v_a = \frac{3.576\times10^{8}\ \text{m}}{4.064\times10^{8}\ \text{m}}\left(1.09\,\text{km/s}\right)$$
$$= \boxed{959\ \text{m/s}}$$

Newton's Law of Gravity

31 • **[SSM]** Jupiter's satellite Europa orbits Jupiter with a period of 3.55 d at an average orbital radius of 6.71 × 10^8 m. (*a*) Assuming that the orbit is circular, determine the mass of Jupiter from the data given. (*b*) Another satellite of Jupiter, Callisto, orbits at an average radius of 18.8 × 10^8 m with an orbital period of 16.7 d. Show that these data are consistent with an inverse square force law for gravity (*Note*: DO NOT use the value of *G* anywhere in Part (*b*)).

Picture the Problem While we could apply Newton's law of gravitation and second law of motion to solve this problem from first principles, we'll use Kepler's third law (derived from these laws) to find the mass of Jupiter in Part (*a*). In Part (*b*) we can compare the ratio of the centripetal accelerations of Europa and Callisto to show that these data are consistent with an inverse square law for gravity.

(*a*) Assuming a circular orbit, apply Kepler's third law to the motion of Europa to obtain:

$$T_{\text{E}}^2 = \frac{4\pi^2}{GM_{\text{J}}}R_{\text{E}}^3 \Rightarrow M_{\text{J}} = \frac{4\pi^2}{GT_{\text{E}}^2}R_{\text{E}}^3$$

Substitute numerical values and evaluate M_J:

$$M_J = \frac{4\pi^2\left(6.71\times10^8\ \text{m}\right)^3}{\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(3.55\,\text{d}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\,\text{s}}{\text{h}}\right)^2} = \boxed{1.90\times10^{27}\ \text{kg}}$$

Note that this result is in excellent agreement with the accepted value of 1.902×10^{27} kg.

(*b*) Express the centripetal acceleration of both of the moons to obtain:

$$a_{\text{centripetal}} = \frac{v^2}{R} = \frac{\left(\frac{2\pi R}{T}\right)^2}{R} = \frac{4\pi^2 R}{T^2}$$

where R and T are the radii and periods of their motion.

Using this result, express the centripetal accelerations of Europa and Callisto:

$$a_E = \frac{4\pi^2 R_E}{T_E^2} \text{ and } a_C = \frac{4\pi^2 R_C}{T_C^2}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{a_E}{a_C} = \frac{\frac{4\pi^2 R_E}{T_E^2}}{\frac{4\pi^2 R_C}{T_C^2}} = \frac{T_C^2}{T_E^2}\frac{R_E}{R_C}$$

Substitute for the periods of Callisto and Europa using Kepler's third law to obtain:

$$\frac{a_E}{a_C} = \frac{CR_C^3}{CR_E^3}\frac{R_E}{R_C} = \frac{R_C^2}{R_E^2}$$

This result, together with the fact that the gravitational force is directly proportional to the acceleration of the moons, demonstrates that the gravitational force varies inversely with the square of the distance.

32 • Some people think that shuttle astronauts are ″weightless″ because they are ″beyond the pull of Earth's gravity. ″ In fact, this is completely untrue. (*a*) What is the magnitude of the gravitational field in the vicinity of a shuttle orbit? A shuttle orbit is about 400 km above the ground. (*b*) Given the answer in Part (*a*), explain why shuttle astronauts do suffer from adverse biological affects such as muscle atrophy even though they are actually not ″weightless″?

Determine the Concept The weight of anything, including astronauts, is the reading of a scale from which the object is suspended or on which it rests. That is, it is the magnitude of the normal force acting on the object. If the scale reads zero, then we say the object is ″weightless.″ The pull of Earth's gravity, on the other hand, depends on the local value of the acceleration of gravity and we can use Newton's law of gravity to find this acceleration at the elevation of the shuttle.

(*a*) Apply Newton's law of gravitation to an astronaut of mass *m* in a shuttle at a distance *h* above the surface of Earth:

$$mg_{\text{shuttle}} = \frac{GmM_{\text{E}}}{(h+R_{\text{E}})^2}$$

Solving for g_{shuttle} yields:

$$g_{\text{shuttle}} = \frac{GM_{\text{E}}}{(h+R_{\text{E}})^2}$$

Substitute numerical values and evaluate g_{shuttle}:

$$g_{\text{shuttle}} = \frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.98\times10^{24}\ \text{kg})}{(400\,\text{km}+6370\,\text{km})^2} = \boxed{8.71\,\text{m/s}^2}$$

(*b*) In orbit, the astronauts experience only one (the gravitational force) of the two forces (the second being the normal force – a compressive force – exerted by Earth) that normally acts on them. Lacking this compressive force, their bones and muscles, in the absence of an exercise program, will weaken. In orbit the astronauts are not weightless, they are normal–forceless.

33 • **[SSM]** The mass of Saturn is 5.69×10^{26} kg. (*a*) Find the period of its moon Mimas, whose mean orbital radius is 1.86×10^8 m. (*b*) Find the mean orbital radius of its moon Titan, whose period is 1.38×10^6 s.

Picture the Problem While we could apply Newton's law of gravitation and second law of motion to solve this problem from first principles, we'll use Kepler's third law (derived from these laws) to find the period of Mimas and to relate the periods of the moons of Saturn to their mean distances from its center.

(*a*) Using Kepler's third law, relate the period of Mimas to its mean distance from the center of Saturn:

$$T_{\text{M}}^2 = \frac{4\pi^2}{GM_{\text{S}}}r_{\text{M}}^3 \Rightarrow T_{\text{M}} = \sqrt{\frac{4\pi^2}{GM_{\text{S}}}r_{\text{M}}^3}$$

Substitute numerical values and evaluate T_{M}:

$$T_{\text{M}} = \sqrt{\frac{4\pi^2(1.86\times10^8\ \text{m})^3}{(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.69\times10^{26}\ \text{kg})}} = 8.18\times10^4\ \text{s} \approx \boxed{22.7\ \text{h}}$$

(*b*) Using Kepler's third law, relate the period of Titan to its mean distance from the center of Saturn:

$$T_T^2 = \frac{4\pi^2}{GM_S} r_T^3 \Rightarrow r_T = \sqrt[3]{\frac{T_T^2 GM_S}{4\pi^2}}$$

Substitute numerical values and evaluate r_T:

$$r_T = \sqrt[3]{\frac{\left(1.38\times10^6\ \text{s}\right)^2\left(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(5.69\times10^{26}\ \text{kg}\right)}{4\pi^2}} = \boxed{1.22\times10^9\ \text{m}}$$

34 • Calculate the mass of Earth from the period of the moon, $T = 27.3$ d; its mean orbital radius, $r_m = 3.84 \times 10^8$ m; and the known value of G.

Picture the Problem While we could apply Newton's law of gravitation and second law of motion to solve this problem from first principles, we'll use Kepler's third law (derived from these laws) to relate the period of the moon to the mass of Earth and the mean Earth-moon distance.

Using Kepler's third law, relate the period of the moon to its mean orbital radius:

$$T_m^2 = \frac{4\pi^2}{GM_E} r_m^3 \Rightarrow M_E = \frac{4\pi^2}{GT_m^2} r_m^3$$

Substitute numerical values and evaluate M_E:

$$M_E = \frac{4\pi^2\left(3.84\times10^8\ \text{m}\right)^3}{\left(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(27.3\,\text{d}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\ \text{s}}{\text{h}}\right)^2} = \boxed{6.02\times10^{24}\ \text{kg}}$$

Remarks: This analysis neglects the mass of the moon; consequently the mass calculated here is slightly too large.

35 • Suppose you leave the Solar System and arrive at a planet that has the same mass-to-volume ratio as Earth but has 10 times Earth's radius. What would you weigh on this planet compared with what you weigh on Earth?

Picture the Problem Your weight is the local gravitational force exerted on you. We can use the definition of density to relate the mass of the planet to the mass of Earth and the law of gravity to relate your weight on the planet to your weight on Earth.

Using the definition of density, relate the mass of Earth to its radius:

$$M_E = \rho V_E = \tfrac{4}{3}\rho\pi R_E^3$$

Relate the mass of the planet to its radius:

$$M_P = \rho V_P = \tfrac{4}{3}\rho\pi R_P^3 = \tfrac{4}{3}\rho\pi(10R_E)^3$$

Divide the second of these equations by the first to express M_P in terms of M_E:

$$\frac{M_P}{M_E} = \rho\frac{\tfrac{4}{3}\rho\pi(10R_E)^3}{\tfrac{4}{3}\rho\pi R_E^3} \Rightarrow M_P = 10^3 M_E$$

Letting w' represent your weight on the planet, use the law of gravity to relate w' to your weight on Earth:

$$w' = \frac{GmM_P}{R_P^2} = \frac{Gm(10^3 M_E)}{(10R_E)^2} = 10\frac{GmM_E}{R_E^2} = 10w$$

Your weight would be ten times your weight on Earth.

36 • Suppose that Earth retained its present mass but was somehow compressed to half its present radius. What would be the value of g at the surface of this new, compact planet?

Picture the Problem We can relate the acceleration due to gravity of a test object at the surface of the new planet to the acceleration due to gravity at the surface of Earth through use of the law of gravity and Newton's second law of motion.

Letting a represent the acceleration due to gravity at the surface of this new planet and m the mass of a test object, apply Newton's second law and the law of gravity to obtain:

$$\sum F_{\text{radial}} = \frac{GmM_E}{\left(\tfrac{1}{2}R_E\right)^2} = ma \Rightarrow a = \frac{GM_E}{\left(\tfrac{1}{2}R_E\right)^2}$$

Simplify this expression to obtain:

$$a = 4\left(\frac{GM_E}{R_E^2}\right) = 4g = \boxed{39.2\,\text{m/s}^2}$$

37 • A planet orbits a massive star. When the planet is at perihelion, it has a speed of 5.0×10^4 m/s and is 1.0×10^{15} m from the star. The orbital radius increases to 2.2×10^{15} m at aphelion. What is the planet's speed at aphelion?

Picture the Problem We can use conservation of angular momentum to relate the planet's speeds at aphelion and perihelion.

Using conservation of angular momentum, relate the angular momenta of the planet at aphelion and perihelion:

$$L_a = L_p$$

or

$$mv_p r_p = mv_a r_a \Rightarrow v_a = \frac{v_p r_p}{r_a}$$

Substitute numerical values and evaluate v_a:

$$v_a = \frac{(5.0\times10^4\text{ m/s})(1.0\times10^{15}\text{ m})}{2.2\times10^{15}\text{ m}} = \boxed{2.3\times10^4\text{ m/s}}$$

38 • What is the magnitude of the gravitational field at the surface of a neutron star whose mass is 1.60 times the mass of the Sun and whose radius is 10.5 km?

Picture the Problem We can use Newton's law of gravity to express the gravitational force acting on an object at the surface of the neutron star in terms of the weight of the object. We can then simplify this expression by dividing out the mass of the object … leaving an expression for the magnitude of the gravitational field at the surface of the neutron star.

Apply Newton's law of gravity to an object of mass m at the surface of the neutron star to obtain:

$$\frac{GM_{\text{Neutron Star}}m}{R^2_{\text{Neutron Star}}} = mg$$

where g represents the magnitude of the gravitational field at the surface of the neutron star.

Solve for g and substitute for the mass of the neutron star:

$$g = \frac{GM_{\text{Neutron Star}}}{R^2_{\text{Neutron Star}}} = \frac{G(1.60M_{\text{sun}})}{R^2_{\text{Neutron Star}}}$$

Substitute numerical values and evaluate g:

$$g = \frac{1.60(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\text{ kg})}{(10.5\text{ km})^2} = \boxed{1.93\times10^{12}\text{ m/s}^2}$$

39 •• The speed of an asteroid is 20 km/s at perihelion and 14 km/s at aphelion. (*a*) Determine the ratio of the aphelion to perihelion distances. (*b*) Is this asteroid farther from the Sun or closer to the Sun than Earth, on average? Explain.

Picture the Problem We can use conservation of angular momentum to relate the asteroid's aphelion and perihelion distances.

(*a*) Using conservation of angular momentum, relate the angular momenta of the asteroid at aphelion and perihelion:

$$L_a - L_p = 0$$

or

$$mv_a r_a - mv_p r_p = 0 \Rightarrow \frac{r_a}{r_p} = \frac{v_p}{v_a}$$

Substitute numerical values and evaluate the ratio of the asteroid's aphelion and perihelion distances:

$$\frac{r_a}{r_p} = \frac{20\,\text{km/s}}{14\,\text{km/s}} = \boxed{1.4}$$

(*b*) It is farther from the Sun than Earth. Kepler's third law ($T^2 = Cr_{av}^3$) tells us that longer orbital periods together with larger orbital radii means slower orbital speeds, so the speed of objects orbiting the Sun decreases with distance from the Sun. The average orbital speed of Earth, given by $v = 2\pi r_{ES}/T_{ES}$, is approximately 30 km/s. Because the given maximum speed of the asteroid is only 20 km/s, the asteroid is farther from the Sun.

40 •• A satellite that has a mass of 300 kg moves in a circular orbit 5.00×10^7 m above Earth's surface. (*a*) What is the gravitational force on the satellite? (*b*) What is the speed of the satellite? (*c*) What is the period of the satellite?

Picture the Problem We'll use the law of gravity to find the gravitational force acting on the satellite. The application of Newton's second law will lead us to the speed of the satellite and its period can be found from its definition.

(*a*) Letting *m* represent the mass of the satellite and *h* its elevation, use the law of gravity to express the gravitational force acting on it:

$$F_g = \frac{GmM_E}{(R_E + h)^2}$$

Because $GM_E = gR_E^2$:

$$F_g = \frac{mR_E^2 g}{(R_E + h)^2}$$

Divide the numerator and denominator of this expression by R_E^2 to obtain:

$$F_g = \frac{mg}{\left(1 + \frac{h}{R_E}\right)^2}$$

Substitute numerical values and evaluate F_g:

$$F_g = \frac{(300\,\text{kg})(9.81\,\text{N/kg})}{\left(1+\dfrac{5.00\times10^7\text{ m}}{6.37\times10^6\text{ m}}\right)^2} = 37.58\,\text{N}$$

$$= \boxed{37.6\,\text{N}}$$

(*b*) Using Newton's second law, relate the gravitational force acting on the satellite to its centripetal acceleration:

$$F_g = m\frac{v^2}{r} \Rightarrow v = \sqrt{\frac{F_g r}{m}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{(37.58\,\text{N})(6.37\times10^6\text{ m} + 5.00\times10^7\text{ m})}{300\,\text{kg}}} = 2.657\text{ km/s} = \boxed{2.66\text{ km/s}}$$

(*c*) The period of the satellite is given by:

$$T = \frac{2\pi r}{v}$$

Substitute numerical values and evaluate T:

$$T = \frac{2\pi(6.37\times10^6\text{ m} + 5.00\times10^7\text{ m})}{2.657\times10^3\text{ m/s}}$$

$$= 1.333\times10^5\text{ s}\times\frac{1\,\text{h}}{3600\,\text{s}} = \boxed{37.0\,\text{h}}$$

41 •• [SSM] A superconducting gravity meter can measure changes in gravity of the order $\Delta g/g = 1.00 \times 10^{-11}$. (*a*) You are hiding behind a tree holding the meter, and your 80-kg friend approaches the tree from the other side. How close to you can your friend get before the meter detects a change in g due to his presence? (*b*) You are in a hot air balloon and are using the meter to determine the rate of ascent (assume the balloon has constant acceleration). What is the smallest change in altitude that results in a detectable change in the gravitational field of Earth?

Picture the Problem We can determine the maximum range at which an object with a given mass can be detected by substituting the equation for the gravitational field in the expression for the resolution of the meter and solving for the distance. Differentiating $g(r)$ with respect to r, separating variables to obtain dg/g, and approximating Δr with dr will allow us to determine the vertical change in the position of the gravity meter in Earth's gravitational field is detectable.

(*a*) Earth's gravitational field is given by:

$$g_E = \frac{GM_E}{R_E^2}$$

Express the gravitational field due to the mass *m* (assumed to be a point mass) of your friend and relate it to the resolution of the meter:

$$g(r) = \frac{Gm}{r^2} = 1.00\times10^{-11}\, g_E$$
$$= 1.00\times10^{-11}\frac{GM_E}{R_E^2}$$

Solving for *r* yields:

$$r = R_E\sqrt{\frac{1.00\times10^{11}\, m}{M_E}}$$

Substitute numerical values and evaluate *r*:

$$r = (6.37\times10^6\ \text{m})\sqrt{\frac{1.00\times10^{11}(80\,\text{kg})}{5.98\times10^{24}\ \text{kg}}}$$
$$= \boxed{7.37\,\text{m}}$$

(*b*) Differentiate *g*(*r*) and simplify to obtain:

$$\frac{dg}{dr} = \frac{-2Gm}{r^3} = -\frac{2}{r}\left(\frac{Gm}{r^2}\right) = -\frac{2}{r}g$$

Separate variables to obtain:

$$\frac{dg}{g} = -2\frac{dr}{r} = 10^{-11}$$

Approximating *dr* with Δr, evaluate Δr with $r = R_E$:

$$\Delta r = \left|-\tfrac{1}{2}(1.00\times10^{-11})(6.37\times10^6\ \text{m})\right|$$
$$= \boxed{31.9\,\mu\text{m}}$$

42 •• Suppose that the attractive interaction between a star of mass *M* and a planet of mass $m \ll M$ is of the form $F = KMm/r$, where *K* is the gravitational constant. What would be the relation between the radius of the planet's circular orbit and its period?

Picture the Problem We can use the law of gravity and Newton's second law to relate the force exerted on the planet by the star to its orbital speed and the definition of the period to relate it to the radius of the orbit.

The period of the planet is related to its orbital speed:

$$T = \frac{2\pi r}{v} \qquad (1)$$

Using the law of gravity and Newton's second law, relate the force exerted on the planet by the star to its centripetal acceleration:

$$F_{net} = \frac{KMm}{r} = m\frac{v^2}{r} \Rightarrow v = \sqrt{KM}$$

Substitute for v in equation (1) to obtain:

$$T = \boxed{\frac{2\pi}{\sqrt{KM}}r}$$

43 •• **[SSM]** Earth's radius is 6370 km and the moon's radius is 1738 km. The acceleration of gravity at the surface of the moon is 1.62 m/s^2. What is the ratio of the average density of the moon to that of Earth?

Picture the Problem We can use the definitions of the gravitational fields at the surfaces of Earth and the moon to express the accelerations due to gravity at these locations in terms of the average densities of Earth and the moon. Expressing the ratio of these accelerations will lead us to the ratio of the densities.

Express the acceleration due to gravity at the surface of Earth in terms of Earth's average density:

$$g_E = \frac{GM_E}{R_E^2} = \frac{G\rho_E V_E}{R_E^2} = \frac{G\rho_E \frac{4}{3}\pi R_E^3}{R_E^2}$$
$$= \tfrac{4}{3}G\rho_E\pi R_E$$

The acceleration due to gravity at the surface of the moon in terms of the moon's average density is:

$$g_M = \tfrac{4}{3}G\rho_M\pi R_M$$

Divide the second of these equations by the first to obtain:

$$\frac{g_M}{g_E} = \frac{\rho_M R_M}{\rho_E R_E} \Rightarrow \frac{\rho_M}{\rho_E} = \frac{g_M R_E}{g_E R_M}$$

Substitute numerical values and evaluate $\frac{\rho_M}{\rho_E}$:

$$\frac{\rho_M}{\rho_E} = \frac{(1.62\,\text{m/s}^2)(6.37\times10^6\,\text{m})}{(9.81\,\text{m/s}^2)(1.738\times10^6\,\text{m})}$$
$$= \boxed{0.605}$$

Gravitational and Inertial Mass

44 • The weight of a standard object defined as having a mass of exactly 1.00… kg is measured to be 9.81 N. In the same laboratory, a second object weighs 56.6 N. (*a*) What is the mass of the second object? (*b*) Is the mass you determined in Part (*a*) gravitational or inertial mass?

Picture the Problem Newton's second law of motion relates the weights of these two objects to their masses and the acceleration due to gravity.

(*a*) Apply Newton's second law to the standard object:

$$F_{net} = w_1 = m_1 g$$

Apply Newton's second law to the object of unknown mass:

$$F_{net} = w_2 = m_2 g$$

Eliminate g between these two equations and solve for m_2:

$$m_2 = \frac{w_2}{w_1} m_1$$

Substitute numerical values and evaluate m_2:

$$m_2 = \frac{56.6\,\text{N}}{9.81\,\text{N}}(1.00\,\text{kg}) = \boxed{5.77\,\text{kg}}$$

(*b*) Because this result is determined by the effect on m_2 of Earth's gravitational field, it is the *gravitational* mass of the second object.

45 • The *Principle of Equivalence* states that the free-fall acceleration of any object in a gravitational field is independent of the mass of the object. This can be deduced from the law of universal gravitation, but how well does it hold up experimentally? The Roll-Krotkov-Dicke experiment performed in the 1960s indicates that the free-fall acceleration is independent of mass to at least 1 part in 10^{12}. Suppose two objects are simultaneously released from rest in a uniform gravitational field. Also, suppose one of the objects falls with a constant acceleration of exactly 9.81 m/s^2 while the other falls with a constant acceleration that is greater than 9.81 m/s^2 by one part in 10^{12}. How far will the first object have fallen when the second object has fallen 1.00 mm farther than it has? Note that this estimate provides only an upper bound on the difference in the accelerations; most physicists believe that there is no difference in the accelerations.

Picture the Problem Noting that $g_1 \sim g_2 \sim g$, let the acceleration of gravity on the first object be g_1, and on the second be g_2. We can use a constant-acceleration equation to express the difference in the distances fallen by each object and then relate the average distance fallen by the two objects to obtain an expression from which we can approximate the distance they would have to fall before we might measure a difference in their fall distances greater than 1 mm.

Express the difference Δd in the distances fallen by the two objects in time t:

$$\Delta d = d_1 - d_2$$

Express the distances fallen by each of the objects in time t:

$$d_1 = \tfrac{1}{2} g_1 t^2 \text{ and } d_2 = \tfrac{1}{2} g_2 t^2$$

Substitute for d_1 and d_2 to obtain:

$$\Delta d = \tfrac{1}{2} g_1 t^2 - \tfrac{1}{2} g_2 t^2 = \tfrac{1}{2}\left(g_1 - g_2\right) t^2$$

Relate the average distance d fallen by the two objects to their time of fall:

$$d = \tfrac{1}{2} g t^2 \Rightarrow t^2 = \frac{2d}{g}$$

Substitute for t^2 to obtain:

$$\Delta d \approx \tfrac{1}{2} \Delta g \frac{2d}{g} = d \frac{\Delta g}{g} \Rightarrow d = \Delta d \frac{g}{\Delta g}$$

Substitute numerical values and evaluate d:

$$d = \left(10^{-3}\text{ m}\right)\left(10^{12}\right) = \boxed{10^9\text{ m}}$$

Gravitational Potential Energy

46 • (*a*) If we take the potential energy of a 100-kg object and Earth to be zero when the two are separated by an infinite distance, what is the potential energy when the object is at the surface of Earth? (*b*) Find the potential energy of the same object at a height above Earth's surface equal to Earth's radius. (*c*) Find the escape speed for a body projected from this height.

Picture the Problem Choosing the zero of gravitational potential energy to be at infinite separation yields, as the potential energy of a two-body system in which the objects are separated by a distance r, $U(r) = -GMm/r$, where M and m are the masses of the two bodies. In order for an object to just escape a gravitational field from a particular location, it must have enough kinetic energy so that its total energy is zero.

(*a*) Letting $U(\infty) = 0$, express the gravitational potential energy of the Earth-object system:

$$U(r) = -\frac{GM_\text{E} m}{r} \qquad (1)$$

Substitute for GM_E and simplify to obtain:

$$U\left(R_\text{E}\right) = -\frac{GM_\text{E} m}{R_\text{E}} = -\frac{gR_\text{E}^2 m}{R_\text{E}} = -mgR_\text{E}$$

Substitute numerical values and evaluate $U(R_\text{E})$:

$$U\left(R_\text{E}\right) = -(100\text{ kg})(9.81\text{ N/kg})\left(6.37\times10^6\text{ m}\right) = \boxed{-6.25\times10^9\text{ J}}$$

(*b*) Evaluate equation (1) with $r = 2R_\text{E}$:

$$U\left(2R_\text{E}\right) = -\frac{GM_\text{E} m}{2R_\text{E}} = -\frac{gR_\text{E}^2 m}{2R_\text{E}} = -\tfrac{1}{2} mgR_\text{E}$$

Substitute numerical values and evaluate $U(2R_E)$:

$$U(2R_E) = -\tfrac{1}{2}(100\,\text{kg})(9.81\,\text{N/kg})(6.37\times10^6\,\text{m}) = -3.124\times10^9\,\text{J} = \boxed{-3.12\times10^9\,\text{J}}$$

(*c*) Express the condition that an object must satisfy in order to escape from Earth's gravitational field from a height R_E above its surface:

$$K_e(2R_E) + U(2R_E) = 0$$

or

$$\tfrac{1}{2}mv_e^2 + U(2R_E) = 0$$

Solving for v_e yields:

$$v_e = \sqrt{\frac{-2U(2R_E)}{m}}$$

Substitute numerical values and evaluate v_e:

$$v_e = \sqrt{\frac{-2(-3.124\times10^9\,\text{J})}{100\,\text{kg}}} = \boxed{7.90\,\text{km/s}}$$

47 • [SSM] Knowing that the acceleration of gravity on the moon is 0.166 times that on Earth and that the moon's radius is $0.273R_E$, find the escape speed for a projectile leaving the surface of the moon.

Picture the Problem The escape speed from the moon is given by $v_{e,m} = \sqrt{2GM_m/R_m}$, where M_m and R_m represent the mass and radius of the moon, respectively.

Express the escape speed from the moon:

$$v_{e.m} = \sqrt{\frac{2GM_m}{R_m}} = \sqrt{2g_mR_m}$$

Because $g_m = 0.166g_E$ and $R_m = 0.273R_E$:

$$v_{e.m} = \sqrt{2(0.166g_E)(0.273R_E)}$$

Substitute numerical values and evaluate $v_{e,m}$:

$$v_{e.m} = \sqrt{2(0.166)(9.81\,\text{m/s}^2)(0.273)(6.371\times10^6\,\text{m})} = \boxed{2.38\,\text{km/s}}$$

48 •• What initial speed would a particle need to be given at the surface of Earth if it is to have a final speed that is equal to its escape speed when it is very far from Earth? Neglect any effects due to air resistance.

Picture the Problem Let the zero of gravitational potential energy be at infinity, *m* represent the mass of the particle, and the subscript E refer to Earth. When the particle is very far from Earth, the gravitational potential energy of the

Earth-particle system is zero. We'll use conservation of energy to relate the initial potential and kinetic energies of the particle-Earth system to the final kinetic energy of the particle.

Use conservation of energy to relate the initial energy of the system to its energy when the particle is very far away:

$$K_f - K_i + U_f - U_i = 0$$

or, because $U_f = 0$,

$$K(\infty) - K(R_E) - U(R_E) = 0 \qquad (1)$$

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}mv_\infty^2 - \tfrac{1}{2}mv_i^2 + \frac{GM_E m}{R_E} = 0$$

or, because $GM_E = gR_E^2$,

$$\tfrac{1}{2}mv_\infty^2 - \tfrac{1}{2}mv_i^2 + mgR_E = 0$$

Solving for v_i yields:

$$v_i = \sqrt{v_\infty^2 + 2gR_E}$$

Substitute numerical values and evaluate v_i:

$$v_i = \sqrt{(11.2\times10^3\ \text{m/s})^2 + 2(9.81\,\text{m/s}^2)(6.37\times10^6\ \text{m})} = \boxed{15.8\,\text{km/s}}$$

49 •• While trying to work out its budget for the next fiscal year, NASA wants to report to the nation a rough estimate of the cost (per kilogram) of launching a modern satellite into near-Earth orbit. You are chosen for this task, because you know physics and accounting. (*a*) Determine the energy, in kW·h, necessary to place 1.0-kg object in low-Earth orbit. In low-Earth orbit, the height of the object above the surface of Earth is much smaller than Earth's radius. Take the orbital height to be 300 km. (*b*) If this energy can be obtained at a typical electrical energy rate of \$0.15/kW·h, what is the minimum cost of launching a 400-kg satellite into low-Earth orbit? Neglect any effects due to air resistance.

Picture the Problem We can use the expression for the total energy of a satellite to find the energy required to place it in a low-Earth orbit.

(*a*) The total energy of a satellite in a low-Earth orbit is given by:

$$E = K + U_g = \tfrac{1}{2}U_g$$

Substituting for U_g yields:

$$E = -\frac{GM_{\text{Earth}}m_{\text{satellite}}}{2r}$$

where r is the orbital radius and the minus sign indicates the satellite is bound to Earth.

For a near-Earth orbit, $r \approx R_{\text{Earth}}$ and the amount of energy required to place the satellite in orbit becomes:

$$E = \frac{GM_{\text{Earth}}m_{\text{satellite}}}{2R_{\text{Earth}}}$$

Substitute numerical values and evaluate E:

$$E = -\frac{\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(5.98\times10^{24}\ \text{kg}\right)\left(1.0\ \text{kg}\right)}{2\left(6.37\times10^{6}\ \text{m}\right)}$$

$$= 31.31\ \text{MJ}\times\frac{1\,\text{kW}\cdot\text{h}}{3.6\,\text{MJ}} = \boxed{8.7\,\text{kW}\cdot\text{h}}$$

(*b*) Express the cost of this project in terms of the mass of the satellite:

$$\text{Cost} = \text{rate}\times\frac{\text{required energy}}{\text{kg}}\times m_{\text{satellite}}$$

Substitute numerical values and find the cost:

$$\text{Cost} = \frac{\$0.15}{\text{kW}\cdot\text{h}}\times\frac{8.7\,\text{kW}\cdot\text{h}}{\text{kg}}\left(400\,\text{kg}\right) \approx \boxed{\$500}$$

50 •• The science fiction writer Robert Heinlein once said, "If you can get into orbit, then you're halfway to anywhere." Justify this statement by comparing the minimum energy needed to place a satellite into low Earth orbit (h = 400 km) to that needed to set it completely free from the bonds of Earth's gravity. Neglect any effects of air resistance.

Picture the Problem We'll consider a rocket of mass m which is initially on the surface of Earth (mass M and radius R) and compare the kinetic energy needed to get the rocket to its escape speed with its kinetic energy in a low circular orbit around Earth. We can use conservation of energy to find the escape kinetic energy and Newton's law of gravity to derive an expression for the low-Earth orbit kinetic energy.

Apply conservation of energy to relate the initial energy of the rocket to its escape kinetic energy:

$$K_{\text{f}} - K_{\text{i}} + U_{\text{f}} - U_{\text{i}} = 0$$

Letting the zero of gravitational potential energy be at infinity we have $U_{\text{f}} = K_{\text{f}} = 0$ and:

$$-K_{\text{i}} - U_{\text{i}} = 0$$

or

$$K_{\text{e}} = -U_{\text{i}} = \frac{GMm}{R}$$

Apply Newton's law of gravity to the rocket in orbit at the surface of Earth to obtain:

$$\frac{GMm}{R^2} = m\frac{v^2}{R}$$

Rewrite this equation to express the low-Earth orbit kinetic energy K_o of the rocket:

$$K_o = \tfrac{1}{2}mv^2 = \frac{GMm}{2R}$$

Express the ratio of K_o to K_e and simplify to obtain:

$$\frac{K_o}{K_e} = \frac{\frac{GMm}{2R}}{\frac{GMm}{R}} = \frac{1}{2}$$

Solving for K_e yields:

$K_e = \boxed{2K_o}$ as asserted by Heinlein.

51 •• **[SSM]** An object is dropped from rest from a height of 4.0×10^6 m above the surface of Earth. If there is no air resistance, what is its speed when it strikes Earth?

Picture the Problem Let the zero of gravitational potential energy be at infinity and let m represent the mass of the object. We'll use conservation of energy to relate the initial potential energy of the object-Earth system to the final potential and kinetic energies.

Use conservation of energy to relate the initial potential energy of the system to its energy as the object is about to strike Earth:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_i = 0$,

$$K(R_E) + U(R_E) - U(R_E + h) = 0 \qquad (1)$$

where h is the initial height above Earth's surface.

Express the potential energy of the object-Earth system when the object is at a distance r from the surface of Earth:

$$U(r) = -\frac{GM_E m}{r}$$

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}mv^2 - \frac{GM_E m}{R_E} + \frac{GM_E m}{R_E + h} = 0$$

Solving for v yields:

$$v=\sqrt{2\left(\frac{GM_E}{R_E}-\frac{GM_E}{R_E+h}\right)}$$
$$=\sqrt{2gR_E\left(\frac{h}{R_E+h}\right)}$$

Substitute numerical values and evaluate v:

$$v=\sqrt{\frac{2(9.81\,\text{m/s}^2)(6.37\times10^6\,\text{m})(4.0\times10^6\,\text{m})}{6.37\times10^6\,\text{m}+4.0\times10^6\,\text{m}}}=\boxed{6.9\,\text{km/s}}$$

52 •• An object is projected straight upward from the surface of Earth with an initial speed of 4.0 km/s. What is the maximum height it reaches?

Picture the Problem Let the zero of gravitational potential energy be at infinity, m represent the mass of the object, and h the maximum height reached by the object. We'll use conservation of energy to relate the initial potential and kinetic energies of the object-Earth system to the final potential energy.

Use conservation of energy to relate the initial potential energy of the system to its energy as the object is at its maximum height:

$$K_f-K_i+U_f-U_i=0$$

or, because $K_f = 0$,

$$K(R_E)+U(R_E)-U(R_E+h)=0 \quad (1)$$

where h is the maximum height above Earth's surface.

Express the potential energy of the object-Earth system when the object is at a distance r from the surface of Earth:

$$U(r)=-\frac{GM_Em}{r}$$

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}mv^2-\frac{GM_Em}{R_E}+\frac{GM_Em}{R_E+h}=0$$

Solving for h yields:

$$h=\frac{R_E}{\dfrac{2gR_E}{v^2}-1}$$

Substitute numerical values and evaluate h:

$$h = \frac{6.37\times10^{6}\text{ m}}{\dfrac{2\left(9.81\text{ m/s}^2\right)\left(6.37\times10^{6}\text{ m}\right)}{\left(4.0\times10^{3}\text{ m/s}\right)^2}-1} = \boxed{9.4\times10^{5}\text{ m}}$$

53 •• A particle is projected from the surface of Earth with a speed twice the escape speed. When it is very far from Earth, what is its speed?

Picture the Problem Let the zero of gravitational potential energy be at infinity, m represent the mass of the particle, and the subscript E refer to Earth. When the particle is very far from Earth, the gravitational potential energy of Earth-particle system will be zero. We'll use conservation of energy to relate the initial potential and kinetic energies of the particle-Earth system to the final kinetic energy of the particle.

Use conservation of energy to relate the initial energy of the system to its energy when the particle is very far from Earth:

$$K_f - K_i + U_f - U_i = 0$$

or, because $U_f = 0$,

$$K(\infty) - K(R_E) - U(R_E) = 0 \qquad (1)$$

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}mv_\infty^2 - \tfrac{1}{2}m(2v_e)^2 + \frac{GM_E m}{R_E} = 0$$

or, because $GM_E = gR_E^2$,

$$\tfrac{1}{2}mv_\infty^2 - 2mv_e^2 + mgR_E = 0$$

Solving for v_∞ yields:

$$v_\infty = \sqrt{2\left(2v_e^2 - gR_E\right)}$$

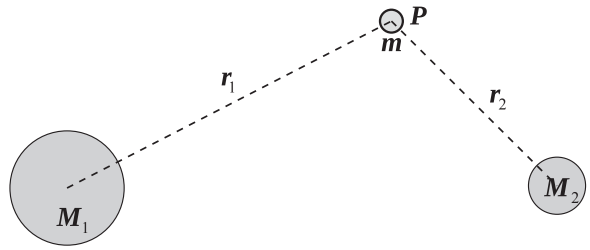
Substitute numerical values and evaluate v_∞:

$$v_\infty = \sqrt{2\left[2\left(11.2\times10^{3}\text{ m/s}\right)^2 - \left(9.81\text{ m/s}^2\right)\left(6.37\times10^{6}\text{ m}\right)\right]} = \boxed{19.4\text{ km/s}}$$

54 ••• When we calculate escape speeds, we usually do so with the assumption that the body from which we are calculating escape speed is isolated. This is, of course, generally not true in the Solar system. Show that the escape speed at a point near a system that consists of two massive spherical bodies is equal to the square root of the sum of the squares of the escape speeds from each of the two bodies considered individually.

Picture the Problem The pictorial representation shows the two massive objects from which the object (whose mass is m), located at point P, is to escape. This

object will have escaped the gravitational fields of the two massive objects provided, when its gravitational potential energy has become zero, its kinetic energy will also be zero.



Express the total energy of the system consisting of the two massive objects and the object whose mass is m:

$$E = \tfrac{1}{2}mv^2 - \frac{GM_1 m}{r_1} - \frac{GM_2 m}{r_2}$$

When the object whose mass is m has escaped, $E = 0$ and:

$$0 = \tfrac{1}{2}mv_e^2 - \frac{GM_1 m}{r_1} - \frac{GM_2 m}{r_2}$$

Solving for v_e yields:

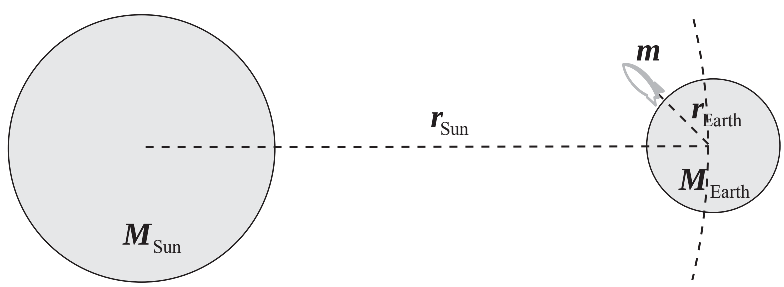
$$v_e^2 = \frac{2GM_1}{r_1} + \frac{2GM_2}{r_2}$$

The terms on the right-hand side of the equation are the squares of the escape speeds from the objects whose masses are M_1 and M_2. Hence;

$$v_e^2 = \boxed{v_{e,1}^2 + v_{e,2}^2}$$

55 ••• Calculate the minimum necessary speed, relative to Earth, for a projectile launched from the surface of Earth to escape the solar system. The answer will depend on the direction of the launch. Explain the choice of direction you'd make for the direction of the launch in order to minimize the necessary launch speed relative to Earth. Neglect Earth's rotational motion and any effects due to air resistance.

Picture the Problem The pictorial representation summarizes the initial positions of the Sun, Earth, and rocket.



From Problem 54, the escape speed from the Earth-Sun system is given by:

$$v_e^2 = \frac{2GM_{Earth}}{r_{Earth}} + \frac{2GM_{Sun}}{r_{Sun}}$$

Solving for v_e yields:

$$v_e = \sqrt{2G\left(\frac{M_{Earth}}{r_{Earth}} + \frac{M_{Sun}}{r_{Sun}}\right)}$$

Substitute numerical values and evaluate v_e:

$$v_e = \sqrt{2\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(\frac{5.98\times10^{24}\ \text{kg}}{6.37\times10^{6}\ \text{m}} + \frac{1.99\times10^{30}\ \text{kg}}{1.496\times10^{11}\ \text{m}}\right)} = 43.6\ \text{km/s}$$

What we have just calculated is the escape speed from Earth's surface, at Earth's orbit. Because the launch will take place from a moving Earth, we need to consider Earth's motion and use it to our advantage. If we launch at sunrise from the Equator, zenith will be pointed directly along the direction of motion of Earth and the required launch speed will be the *minimum* launch speed.

Express the minimum launch speed in terms of the escape speed calculated above and Earth's orbital speed:

$$v_{min} = v_e - v_{orbital}$$

The orbital speed of Earth is given by:

$$v_{orbital} = \frac{2\pi\, r_{orbital}}{T_{orbital}}$$

Substituting for $v_{orbital}$ yields:

$$v_{min} = v_e - \frac{2\pi\, r_{orbital}}{T_{orbital}}$$

Substitute numerical values and evaluate v_{min}:

$$v_{min} = 43.6\ \text{km/s} - \frac{2\pi\left(1.496\times10^{11}\ \text{m}\right)}{1\ \text{y}\times\frac{365.24\ \text{d}}{\text{y}}\times\frac{8.64\times10^{4}\ \text{s}}{\text{d}}} = \boxed{13.8\ \text{km/s}}$$

56 ••• An object is projected vertically from the surface of Earth at less than the escape speed. Show that the maximum height reached by the object is $H = R_E H'/(R_E - H')$, where H' is the height that it would reach if the gravitational field were constant. Neglect any effects due to air resistance.

Picture the Problem Let m represent the mass of the body that is projected vertically from the surface of Earth. We'll begin by using conservation of energy under the assumption that the gravitational field is constant to determine H'. We'll apply conservation of energy a second time, with the zero of gravitational potential energy at infinity, to express H. Finally, we'll solve these two equations simultaneously to express H in terms of H'.

Assuming the gravitational field to be constant and letting the zero of potential energy be at the surface of Earth, apply conservation of mechanical energy to relate the initial kinetic energy and the final potential energy of the object-Earth system:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f to obtain:

$$-\tfrac{1}{2}mv^2 + mgH' = 0 \Rightarrow H' = \frac{v^2}{2g} \quad (1)$$

Letting the zero of gravitational potential energy be at infinity, use conservation of mechanical energy to relate the initial kinetic energy and the final potential energy of the object-Earth system:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = 0$,

$$-K_i + U_f - U_i = 0$$

Substitute for K_i, U_f, and U_i and simplify to obtain:

$$-\tfrac{1}{2}mv^2 - \frac{GMm}{R_E + H} + \frac{GMm}{R_E} = 0$$

or

$$-\tfrac{1}{2}v^2 - \frac{gR_E^2}{R_E + H} + \frac{gR_E^2}{R_E} = 0$$

Solving for v^2 yields:

$$v^2 = 2gR_E^2\left(\frac{1}{R_E} - \frac{1}{R_E + H}\right) = 2gR_E\left(\frac{H}{R_E + H}\right)$$

Substitute in equation (1) to obtain:

$$H' = R_E\left(\frac{H}{R_E + H}\right) \Rightarrow H = \boxed{\frac{H'R_E}{R_E - H'}}$$

Gravitational Orbits

57 •• A 100-kg spacecraft is in a circular orbit about Earth at a height $h = 2R_E$. (*a*) What is the orbital period of the spacecraft? (*b*) What is the spacecraft's kinetic energy? (*c*) Express the angular momentum L of the spacecraft about the center of Earth in terms of its kinetic energy K and find the numerical value of L.

Picture the Problem We can use its definition to express the period of the spacecraft's motion and apply Newton's second law to the spacecraft to determine its orbital speed. We can then use this orbital speed to calculate the kinetic energy of the spacecraft. We can relate the spacecraft's angular momentum to its kinetic energy and moment of inertia.

(*a*) Express the period of the spacecraft's orbit about Earth:

$$T = \frac{2\pi R}{v} = \frac{2\pi(3R_E)}{v} = \frac{6\pi R_E}{v}$$

where v is the orbital speed of the spacecraft.

Use Newton's second law to relate the gravitational force acting on the spacecraft to its orbital speed:

$$F_{\text{radial}} = \frac{GM_E m}{(3R_E)^2} = m\frac{v^2}{3R_E} \Rightarrow v = \sqrt{\frac{gR_E}{3}}$$

Substitute for v in our expression for T to obtain:

$$T = 6\sqrt{3}\pi\sqrt{\frac{R_E}{g}}$$

Substitute numerical values and evaluate T:

$$T = 6\sqrt{3}\pi\sqrt{\frac{6.37\times10^6\ \text{m}}{9.81\ \text{m/s}^2}}$$

$$= 2.631\times10^4\ \text{s}\times\frac{1\ \text{h}}{3600\ \text{s}} = \boxed{7.31\ \text{h}}$$

(*b*) Using its definition, express the spacecraft's kinetic energy:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}m\left(\tfrac{1}{3}gR_E\right)$$

Substitute numerical values and evaluate K:

$$K = \tfrac{1}{6}(100\ \text{kg})(9.81\ \text{m/s}^2)(6.37\times10^6\ \text{m})$$

$$= 1.041\ \text{GJ} = \boxed{1.04\ \text{GJ}}$$

(*c*) Express the kinetic energy of the spacecraft in terms of its angular momentum:

$$K = \frac{L^2}{2I} \Rightarrow L = \sqrt{2IK}$$

Express the moment of inertia of the spacecraft with respect to an axis through the center of Earth:

$$I = m(3R_E)^2 = 9mR_E^2$$

Substitute for I in the expression for L and simplify to obtain:

$$L = \sqrt{2(9mR_E^2)K} = 3R_E\sqrt{2mK}$$

Substitute numerical values and evaluate L:

$$L = 3(6.37\times10^6\ \text{m})\sqrt{2(100\ \text{kg})(1.041\times10^9\ \text{J})} = \boxed{8.72\times10^{12}\ \text{J}\cdot\text{s}}$$

58 •• The orbital period of the moon is 27.3 d, the average center-to-center distance between the moon and Earth is 3.82×10^8 m, the length of a year is 365.24 d, and the average center-to-center distance between Earth and the Sun is 1.50×10^{11} m. Use this data to estimate the ratio of the mass of the Sun to the mass of Earth. Compare this to the measured ratio of 3.33×10^5. List some neglected factors that might account for any discrepancy.

Picture the Problem We can use Kepler's third law to relate the periods of the moon and Earth, in their orbits about Earth and the Sun, to their mean center-to-center distances from the objects about which they orbit. We can solve these equations for the masses of the Sun and Earth and then divide one by the other to establish a value for the ratio of the mass of the Sun to the mass of Earth.

Using Kepler's third law, relate the period of the moon to its mean distance from Earth:

$$T_m^2 = \frac{4\pi^2}{GM_E}r_m^3 \qquad (1)$$

where r_m is the distance between the centers of Earth and the moon.

Using Kepler's third law, relate the period of Earth to its mean distance from the Sun:

$$T_E^2 = \frac{4\pi^2}{GM_s}r_E^3 \qquad (2)$$

where r_E is the distance between the centers of Earth and the Sun.

Solve equation (1) for M_E:

$$M_E = \frac{4\pi^2}{GT_m^2}r_m^3 \qquad (3)$$

Solve equation (2) for M_s:

$$M_s = \frac{4\pi^2}{GT_E^2}r_E^3 \qquad (4)$$

Divide equation (4) by equation (3) and simplify to obtain:

$$\frac{M_s}{M_E} = \left(\frac{r_E}{r_m}\right)^3\left(\frac{T_m}{T_E}\right)^2$$

Substitute numerical values and evaluate M_s/M_E:

$$\frac{M_s}{M_E} = \left(\frac{1.50\times10^{11}\text{ m}}{3.82\times10^{8}\text{ m}}\right)^3\left(\frac{27.3\text{d}}{365.24\text{d}}\right)^2 = \boxed{3.38\times10^5}$$

Express the difference between this value and the measured value of 3.33×10^5:

$$\%\,\text{diff} = \frac{3.38\times10^5 - 3.33\times10^5}{3.33\times10^5} = \boxed{1.50\,\%}$$

In this analysis we've neglected gravitational forces exerted by other planets and the Sun.

59 •• [SSM] Many satellites orbit Earth with maximum altitudes of 1000 km or less. *Geosynchronous* satellites, however, orbit at an altitude of 35 790 km above Earth's surface. How much more energy is required to launch a 500-kg satellite into a geosynchronous orbit than into an orbit 1000 km above the surface of Earth?

Picture the Problem We can express the energy difference between these two orbits in terms of the total energy of a satellite at each elevation. The application of Newton's second law to the force acting on a satellite will allow us to express the total energy of each satellite as a function of its mass, the radius of Earth, and its orbital radius.

Express the energy difference:

$$\Delta E = E_{\text{geo}} - E_{1000} \qquad (1)$$

Express the total energy of an orbiting satellite:

$$E_{\text{tot}} = K + U = \tfrac{1}{2}mv^2 - \frac{GM_E m}{R} \qquad (2)$$

where R is the orbital radius.

Apply Newton's second law to a satellite to relate the gravitational force to the orbital speed:

$$F_{\text{radial}} = \frac{GM_E m}{R^2} = m\frac{v^2}{R}$$

Solving for v^2 yields:

$$v^2 = \frac{gR_E^2}{R}$$

Substitute in equation (2) to obtain:

$$E_{\text{tot}} = \tfrac{1}{2}m\frac{gR_E^2}{R} - \frac{gR_E^2 m}{R} = -\frac{mgR_E^2}{2R}$$

Substituting in equation (1) and simplifying yields:

$$\Delta E = -\frac{mgR_E^2}{2R_{geo}} + \frac{mgR_E^2}{2R_{1000}} = \frac{mgR_E^2}{2}\left(\frac{1}{R_{1000}} - \frac{1}{R_{geo}}\right)$$
$$= \frac{mgR_E^2}{2}\left(\frac{1}{R_E + 1000\,\text{km}} - \frac{1}{R_E + 35\ 790\,\text{km}}\right)$$

Substitute numerical values and evaluate ΔE:

$$\Delta E = \frac{(500\,\text{kg})(9.81\,\text{N/kg})(6.37\times10^6\,\text{m})^2}{2}\left(\frac{1}{7.37\times10^6\,\text{m}} - \frac{1}{4.22\times107\,\text{m}}\right) = \boxed{11.1\,\text{GJ}}$$

60 ••• The idea of a spaceport orbiting Earth is an attractive proposition for launching probes and/or manned missions to the outer planets of the Solar System. Suppose such a ″platform″ has been constructed, and orbits Earth at a distance of 450 km above Earth's surface. Your research team is launching a lunar probe into an orbit that has its perigee at the spaceport's orbital radius, and its apogee at the moon's orbital radius. (*a*) To launch the probe successfully, first determine the orbital speed for the platform. (*b*) Next, determine the necessary speed relative to the platform that is necessary to launch the probe so that it attains the desired orbit. Assume that any effects due to the gravitational pull of the moon on the probe are negligible. In addition, assume that the launch takes place in a negligible amount of time. (*c*) You have the probe designed to radio back when it has reached apogee. How long after launch should you expect to receive this signal from the probe (neglect the second or so delay for the transit time of the signal back to the platform)?

Picture the Problem We can use the fact that the kinetic energy of the orbiting platform equals half its gravitational potential energy to find the orbital speed of the platform. In Part (*b*), the required launch speed is the difference between the speed of the probe at perigee and the orbital speed of the platform. To find the speed of the probe at perigee, we can use conservation of mechanical energy and Kepler's law of equal areas. Finally, in Part (*c*), we can use Kepler's third law to find the time after launch that you would expect to receive a signal from the probe announcing that it had reached apogee.

(*a*) The kinetic energy of the orbiting platform equals half its gravitational potential energy:

$$K = \frac{1}{2}U_g$$

Substitute for K and U to obtain:

$$\frac{1}{2}mv^2 = \frac{1}{2}\frac{GM_{\text{Earth}}m}{r}$$

where m is the mass of the platform and r is the distance from the center of Earth to the platform.

Solving for v yields:

$$v = \sqrt{\frac{GM_{\text{Earth}}}{r}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.98\times10^{24}\ \text{kg})}{6.37\times10^6\ \text{m} + 0.450\times10^6\ \text{m}}} = \boxed{7.65\ \text{km/s}}$$

(*b*) The required launch speed is the difference between the speed of the probe at perigee and the orbital speed of the platform:

$$v_{\text{rel to platform}} = v_{\text{p}} - v \quad (1)$$

Here the platform's orbital radius will be the probe's orbit's perigee; the speed of launch will point in the direction the platform is moving at launch time. Neglecting everything in the universe but Earth and probe, apply conservation of energy from perigee to apogee to obtain:

$$\tfrac{1}{2}mv_{\text{p}}^2 - \tfrac{1}{2}mv_{\text{a}}^2 - \frac{GmM_{\text{Earth}}}{r_{\text{p}}} - \left(-\frac{GmM_{\text{Earth}}}{r_{\text{a}}}\right) = 0$$

Simplify this expression to obtain:

$$v_{\text{p}}^2\left[1-\left(\frac{v_{\text{a}}}{v_{\text{p}}}\right)\right] = 2GM_{\text{Earth}}\left(\frac{1}{r_{\text{p}}} - \frac{1}{r_{\text{a}}}\right) \quad (2)$$

Applying Kepler's law of equal areas between perigee and apogee yields:

$$v_{\text{p}}r_{\text{p}} = v_{\text{a}}r_{\text{a}} \Rightarrow v_{\text{a}} = \frac{r_{\text{p}}}{r_{\text{a}}}v_{\text{p}}$$

Substituting for v_{a} in equation (2) yields:

$$v_{\text{p}}^2\left[1-\left(\frac{r_{\text{p}}}{r_{\text{a}}}\right)\right] = 2GM_{\text{Earth}}\left(\frac{1}{r_{\text{p}}} - \frac{1}{r_{\text{a}}}\right) \quad (3)$$

where

$$r_{\text{p}} = R_{\text{Earth}} + h = 6370\ \text{km} + 450\ \text{km}$$
$$= 6820\ \text{km}$$

and

$$r_{\text{a}} = 3.84\times10^5\ \text{km}$$

Because $r_p << r_a$, equation (3) becomes:

$$v_p^2 \approx 2GM_{\text{Earth}}\left(\frac{1}{r_p}\right) = \frac{2GM_{\text{Earth}}}{r_p}$$

Solving for v_p yields:

$$v_p \approx \sqrt{\frac{2GM_{\text{Earth}}}{r_p}}$$

Substitute numerical values and evaluate v_p:

$$v_p \approx \sqrt{\frac{2(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.98\times10^{24}\ \text{kg})}{6820\ \text{km}}} = 10.8\ \text{km/s}$$

Substitute numerical values in equation (1) and evaluate $v_{\text{rel to platform}}$:

$$v_{\text{rel to platform}} = 10.8\ \text{km/s} - 7.65\ \text{km/s} = \boxed{3.2\ \text{km/s}}$$

(*c*) The time after launch that you should expect to receive this signal from the probe is half the period of the probe's motion:

$$\Delta t = \tfrac{1}{2}T \qquad (4)$$

Apply Kepler's third law to the probe-Earth system to obtain:

$$T^2 = \frac{4\pi^2}{GM_{\text{Earth}}}a^3 \Rightarrow T = \sqrt{\frac{4\pi^2 a^3}{GM_{\text{Earth}}}}$$

where a is the semi-major axis.

Substitute for T in equation (4) to obtain:

$$\Delta t = \sqrt{\frac{\pi^2 a^3}{GM_{\text{Earth}}}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \sqrt{\frac{\pi^2\left[\frac{1}{2}\left(3.844\times10^8\ \text{m} + (6.37+0.45)\times10^6\ \text{m}\right)\right]^3}{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.98\times10^{24}\ \text{kg})}} = 4.303\times10^5\ \text{s} \approx \boxed{5.0\ \text{d}}$$

The Gravitational Field ($\vec{g}$)

61 • A 3.0-kg space probe experiences a gravitational force of $12\ \text{N}\,\hat{i}$ as it passes through point P. What is the gravitational field at point P?

Picture the Problem The gravitational field at any point is defined by $\vec{g} = \vec{F}/m$.

Using its definition, express the gravitational field at a point in space:

$$\vec{g}=\frac{\vec{F}}{m}=\frac{(12\,\text{N})\hat{i}}{3.0\,\text{kg}}=\boxed{(4.0\,\text{N/kg})\hat{i}}$$

62 • The gravitational field at some point is given by $\vec{g}=2.5\times10^{-6}$ N/kg $\hat{j}$. What is the gravitational force on a 0.0040-kg object located at that point?

Picture the Problem The gravitational force acting on an object of mass m where the gravitational field is $\vec{g}$ is given by $\vec{F}=m\vec{g}$.

The gravitational force acting on the object is the product of the mass of the object and the gravitational field:

$$\vec{F}=m\vec{g}$$

Substitute numerical values and evaluate $\vec{g}$:

$$\vec{F}=(0.0040\,\text{kg})(2.5\times10^{-6}\,\text{N/kg})\hat{j}$$
$$=\boxed{(1.0\times10^{-8}\,N)\hat{j}}$$

63 •• **[SSM]** A point particle of mass m is on the x axis at $x = L$ and an identical point particle is on the y axis at $y = L$. (a) What is the direction of the gravitational field at the origin? (b) What is the magnitude of this field?

Picture the Problem We can use the definition of the gravitational field due to a point mass to find the x and y components of the field at the origin and then add these components to find the resultant field. We can find the magnitude of the field from its components using the Pythagorean theorem.

(a) The gravitational field at the origin is the sum of its x and y components:

$$\vec{g}=\vec{g}_x+\vec{g}_y \qquad (1)$$

Express the gravitational field due to the point mass at $x = L$:

$$\vec{g}_x=\frac{Gm}{L^2}\hat{i}$$

Express the gravitational field due to the point mass at $y = L$:

$$\vec{g}_y=\frac{Gm}{L^2}\hat{j}$$

Substitute in equation (1) to obtain:

$$\vec{g}=\vec{g}_x+\vec{g}_y=\frac{Gm}{L^2}\hat{i}+\frac{Gm}{L^2}\hat{j}\Rightarrow$$ the direction of the gravitational field is along a line at 45° above the $+x$ axis.

(b) The magnitude of $\vec{g}$ is given by:

$$|\vec{g}| = \sqrt{g_x^2 + g_y^2}$$

Substitute for g_x and g_y and simplify to obtain:

$$|\vec{g}| = \sqrt{\left(\frac{Gm}{L^2}\right)^2 + \left(\frac{Gm}{L^2}\right)^2} = \boxed{\sqrt{2}\,\frac{Gm}{L^2}}$$

64 •• Five objects, each of mass M, are equally spaced on the arc of a semicircle of radius R as in Figure 11-25. An object of mass m is located at the center of curvature of the arc. (a) If M is 3.0 kg, m is 2.0 kg, and R is 10 cm, what is the gravitational force on the particle of mass m due to the five objects? (b) If the object whose mass is m is removed, what is the gravitational field at the center of curvature of the arc?

Picture the Problem We can find the net force acting on m by superposition of the forces due to each of the objects arrayed on the circular arc. Once we have expressed the net force, we can find the gravitational field at the center of curvature from its definition. Choose a coordinate system in which the $+x$ direction is to the right and the $+y$ direction is upward.

(a) Express the net force acting on the object whose mass is m:

$$\vec{F} = F_x\hat{i} + F_y\hat{j} \qquad (1)$$

F_x is given by:

$$F_x = \frac{GMm}{R^2} - \frac{GMm}{R^2} + \frac{GMm}{R^2}\cos 45° - \frac{GMm}{R^2}\cos 45° = 0$$

F_y is given by:

$$F_y = \frac{GMm}{R^2} + \frac{GMm}{R^2}\sin 45° + \frac{GMm}{R^2}\sin 45° = \frac{GMm}{R^2}\left(2\sin 45° + 1\right)$$

Substitute numerical values and evaluate F_y:

$$F_y = \frac{\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)(3.0\,\text{kg})}{(0.10\,\text{m})^2}(2.0\,\text{kg})\left(2\sin 45° + 1\right) = 9.67\times10^{-8}\ \text{N}$$

Substitute in equation (1) to obtain:

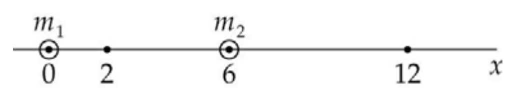
$$\vec{F} = \boxed{0\hat{i} + \left(9.7\times10^{-8}\ \text{N}\right)\hat{j}}$$

(*b*) Using its definition, express $\vec{g}$ at the center of curvature of the arc:

$$\vec{g} = \frac{\vec{F}}{m} = \frac{0\hat{i} + (9.67\times10^{-8}\ \text{N})\hat{j}}{2.0\,\text{kg}}$$
$$= \boxed{(4.8\times10^{-8}\ \text{N/kg})\hat{j}}$$

65 •• A point particle of mass $m_1 = 2.0$ kg is at the origin and a second point particle of mass $m_2 = 4.0$ kg is on the x axis at $x = 6.0$ m. Find the gravitational field $\vec{g}$ at (*a*) $x = 2.0$ m and (*b*) $x = 12$ m. (*c*) Find the point on the x axis for which $g = 0$.

Picture the Problem The configuration of point masses is shown to the right. The gravitational field at any point can be found by superimposing the fields due to each of the point masses.



(*a*) Express the gravitational field at $x = 2.0$ m as the sum of the fields due to the point masses m_1 and m_2:

$$\vec{g} = \vec{g}_1 + \vec{g}_2 \qquad (1)$$

Express $\vec{g}_1$ and $\vec{g}_2$:

$$\vec{g}_1 = -\frac{Gm_1}{x_1^2}\hat{i} \text{ and } \vec{g}_2 = \frac{Gm_2}{x_2^2}\hat{i}$$

Substitute in equation (1) to obtain:

$$\vec{g} = -\frac{Gm_1}{x_1^2}\hat{i} + \frac{Gm_2}{x_2^2}\hat{i} = -\frac{Gm_1}{x_1^2}\hat{i} + \frac{Gm_2}{(2x_1)^2}\hat{i} = -\frac{G}{x_1^2}\left(m_1 - \tfrac{1}{4}m_2\right)\hat{i}$$

Substitute numerical values and evaluate $\vec{g}$:

$$\vec{g} = -\frac{6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2}{(2.0\,\text{m})^2}\left[2.0\,\text{kg} - \tfrac{1}{4}(4.0\,\text{kg})\right]\hat{i} = \boxed{(-1.7\times10^{-11}\ \text{N/kg})\hat{i}}$$

(*b*) Express $\vec{g}_1$ and $\vec{g}_2$:

$$\vec{g}_1 = -\frac{Gm_1}{x_1^2}\hat{i} \text{ and } \vec{g}_2 = -\frac{Gm_2}{x_2^2}\hat{i}$$

Substitute in equation (1) and simplify to obtain:

$$\vec{g} = -\frac{Gm_1}{x_1^2}\hat{i} - \frac{Gm_2}{x_2^2}\hat{i} = -\frac{Gm_1}{(2x_2)^2}\hat{i} - \frac{Gm_2}{x_2^2}\hat{i} = -\frac{G}{x_2^2}\left(\tfrac{1}{4}m_1 + m_2\right)\hat{i}$$

Substitute numerical values and evaluate $\vec{g}$:

$$\vec{g} = -\frac{6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2}{(6.0\,\text{m})^2}\left[\tfrac{1}{4}(2.0\,\text{kg})+4.0\,\text{kg}\right]\hat{i} = \boxed{\left(-8.3\times10^{-12}\ \text{N/kg}\right)\hat{i}}$$

(c) Express the condition that $\vec{g} = 0$:

$$\frac{Gm_1}{x^2}-\frac{Gm_2}{(6.0-x)^2}=0$$

or

$$\frac{2.0}{\boldsymbol{x}^2}-\frac{4.0}{(6.0-\boldsymbol{x})^2}=0$$

Solve this quadratic equation to obtain:

$$x = 2.48\,\text{m} \text{ and } x = -14.5\,\text{m}$$

From the diagram it is clear that the physically meaningful root is the positive one at:

$$x = \boxed{2.5\,\text{m}}$$

66 •• Show that on the x axis, the maximum value of g for the field of Example 11-7 occurs at points $x = \pm a/\sqrt{2}$.

Picture the Problem To show that, on the x axis, the maximum value of g for the field of Example 11-7 occurs at the points $x = \pm a/\sqrt{2}$, we can differentiate g_x with respect to x and set the derivative equal to zero.

From Example 11-7:

$$g_x = -\frac{2GMx}{\left(x^2+a^2\right)^{3/2}}$$

Differentiate g_x with respect to x and set the derivative equal to zero to find extreme values:

$$\frac{dg_x}{dx} = -2GM\left[\left(x^2+a^2\right)^{-3/2} - 3x^2\left(x^2+a^2\right)^{-5/2}\right] = 0 \text{ for extrema.}$$

Solve for x to obtain:

$$x = \boxed{\pm\frac{a}{\sqrt{2}}}$$

Remarks: To establish that this value for *x* corresponds to a relative maximum, we need to either evaluate the second derivative of g_x at

$x = \pm a/\sqrt{2}$ or examine the graph of $|g_x|$ at $x = \pm a/\sqrt{2}$ for concavity downward.

67 ••• [SSM] A nonuniform thin rod of length L lies on the x axis. One end of the rod is at the origin, and the other end is at $x = L$. The rod's mass per unit length λ varies as $\lambda = Cx$, where C is a constant. (Thus, an element of the rod has mass $dm = \lambda\, dx$.) (*a*) What is the total mass of the rod? (*b*) Find the gravitational field due to the rod on the x axis at $x = x_0$, where $x_0 > L$.

Picture the Problem We can find the mass of the rod by integrating dm over its length. The gravitational field at $x_0 > L$ can be found by integrating $d\vec{g}$ at x_0 over the length of the rod.

(*a*) The total mass of the stick is given by:

$$M = \int_0^L \lambda\, dx$$

Substitute for λ and evaluate the integral to obtain"

$$M = C\int_0^L x dx = \boxed{\tfrac{1}{2}CL^2}$$

(*b*) Express the gravitational field due to an element of the stick of mass dm:

$$d\vec{g} = -\frac{Gdm}{(x_0 - x)^2}\hat{i} = -\frac{G\lambda\, dx}{(x_0 - x)^2}\hat{i} = -\frac{GCxdx}{(x_0 - x)^2}\hat{i}$$

Integrate this expression over the length of the stick to obtain:

$$\vec{g} = -GC\int_0^L \frac{xdx}{(x_0 - x)^2}\hat{i} = \boxed{\frac{2GM}{L^2}\left[\ln\left(\frac{x_0}{x_0 - L}\right) - \left(\frac{L}{x_0 - L}\right)\right]\hat{i}}$$

68 •• A uniform thin rod of mass M and length L lies on the positive x axis with one end at the origin. Consider an element of the rod of length dx, and mass dm, at point x, where $0 < x < L$. (*a*) Show that this element produces a gravitational field at a point x_0 on the x axis in the region $x_0 > L$ is given by $dg_x = -\dfrac{GM}{L(x_0 - x)^2}dx$. (*b*) Integrate this result over the length of the rod to find the total gravitational field at the point x_0 due to the rod. (*c*) Find the gravitational force on a point particle of mass m_0 at x_0. (*d*) Show that for $x_0 >> L$, the field of the rod approximates the field of a point particle of mass M at $x = 0$.

Picture the Problem The elements of the rod of mass dm and length dx produce a gravitational field at any point P located a distance $x_0 > L$ from the origin. We can calculate the total field by integrating the magnitude of the field due to dm from $x = 0$ to $x = L$.

(*a*) Express the gravitational field at P due to the element dm:

$$d\vec{g}_x = -\frac{Gdm}{r^2}\hat{i}$$

Relate dm to dx:

$$dm = \frac{M}{L}dx$$

Express the distance r between dm and point P in terms of x and x_0:

$$r = x_0 - x$$

Substitute these results to express $d\vec{g}_x$ in terms of x and x_0:

$$d\vec{g}_x = \boxed{\left\{-\frac{GM}{L(x_0 - x)^2}dx\right\}\hat{i}}$$

(*b*) Integrate from $x = 0$ to $x = L$ to find the total gravitational field at point P:

$$\vec{g}_x = -\frac{GM}{L}\int_0^L \frac{dx}{(x_0 - x)^2}\hat{i}$$

$$= \left\{-\frac{GM}{L}\left[\frac{1}{x_0 - x}\right]_0^L\right\}\hat{i}$$

$$= \boxed{-\frac{GM}{x_0(x_0 - L)}\hat{i}}$$

(*c*) Use the definition of gravitational field and the result from Part (*b*) to express $\vec{F}_g$ at $x = x_0$:

$$\vec{F}_g = m_0\vec{g} = \boxed{-\frac{GMm_0}{x_0(x_0 - L)}\hat{i}}$$

(*d*) Factor x_0 from the denominator of the expression for $\vec{g}_x$ to obtain:

$$\vec{g}_x = -\frac{GM}{x_0^2\left(1 - \frac{L}{x_0}\right)}\hat{i}$$

For $x_0 >> L$ the second term in parentheses is very small and:

$$\vec{g}_x \approx \boxed{-\frac{GM}{x_0^2}\hat{i}}$$

which is the gravitational field of a point mass M located at the origin.

The Gravitational Field ($\vec{g}$) due to Spherical Objects

69 • A uniform thin spherical shell has a radius of 2.0 m and a mass of 300 kg. What is the gravitational field at the following distances from the center of the shell: (*a*) 0.50 m, (*b*) 1.9 m, (*c*) 2.5 m?

Picture the Problem The gravitational field inside a spherical shell is zero and the field at the surface of and outside the shell is given by $g = GM/r^2$.

(*a*) Because 0.50 m < *R*: $g(0.50\text{ m}) = \boxed{0}$

(*b*) Because 1.9 m < *R*: $g(1.9\text{ m}) = \boxed{0}$

(*c*) Because 2.5 m > *R*:

$$g(2.5\text{ m}) = \frac{GM}{r^2} = \frac{\left(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2\right)(300\text{ kg})}{(2.5\text{ m})^2} = \boxed{3.2\times10^{-9}\text{ N/kg}}$$

70 • A uniform thin spherical shell has a radius of 2.00 m and a mass of 300 kg, and its center is located at the origin of a coordinate system. Another uniform thin spherical shell with a radius of 1.00 m and a mass of 150 kg is inside the larger shell with its center at 0.600 m on the *x* axis. What is the gravitational force of attraction between the two shells?

Determine the Concept The gravitational force is zero. The gravitational field inside the 2.00 m shell due to that shell is zero; therefore, it exerts no force on the 1.00 m-shell, and, by Newton's third law, that shell exerts no force on the larger shell.

71 •• **[SSM]** Two widely separated solid spheres, S_1 and S_2, each have radius *R* and mass *M*. Sphere S_1 is uniform, whereas the density of sphere S_2 is given by $\rho(r) = C/r$, where *r* is the distance from its center. If the gravitational field strength at the surface of S_1 is g_1, what is the gravitational field strength at the surface of S_2?

Picture the Problem The gravitational field strength at the surface of a sphere is given by $g = GM/R^2$, where *R* is the radius of the sphere and *M* is its mass.

Express the gravitational field strength on the surface of S_1: $g_1 = \dfrac{GM}{R^2}$

Express the gravitational field strength on the surface of S_2:

$$g_2 = \frac{GM}{R^2}$$

Divide the second of these equations by the first and simplify to obtain:

$$\frac{g_2}{g_1} = \frac{\frac{GM}{R^2}}{\frac{GM}{R^2}} = 1 \Rightarrow \boxed{g_1 = g_2}$$

72 •• Two widely separated uniform solid spheres, S_1 and S_2, have equal masses but different radii, R_1 and R_2. If the gravitational field strength on the surface of S_1 is g_1, what is the gravitational field strength on the surface of S_2?

Picture the Problem The gravitational field strength at the surface of a sphere is given by $g = GM/R^2$, where R is the radius of the sphere and M is its mass.

Express the gravitational field strength on the surface of S_1:

$$g_1 = \frac{GM}{R_1^2}$$

Express the gravitational field strength on the surface of S_2:

$$g_2 = \frac{GM}{R_2^2}$$

Divide the second of these equations by the first and simplify to obtain:

$$\frac{g_2}{g_1} = \frac{\frac{GM}{R_2^2}}{\frac{GM}{R_1^2}} = \frac{R_1^2}{R_2^2} \Rightarrow g_2 = \boxed{\frac{R_1^2}{R_2^2} g_1}$$

Remarks: The gravitational field strengths depend only on the masses and radii because the points of interest are outside spherically symmetric distributions of mass.

73 •• Two concentric uniform thin spherical shells have masses M_1 and M_2 and radii a and $2a$, as in Figure 11-26. What is the magnitude of the gravitational force on a point particle of mass m (not shown) located (*a*) a distance $3a$ from the center of the shells? (*b*) a distance $1.9a$ from the center of the shells? (*c*) a distance $0.9a$ from the center of the shells?

Picture the Problem The magnitude of the gravitational force is $F_g = mg$ where g inside a spherical shell is zero and outside is given by $g = GM/r^2$.

(*a*) The gravitational force on a particle of mass m is given by:

$$F_g = mg$$

At $r = 3a$, the masses of both spheres contribute to g:

$$F_g(3a) = m\frac{G(M_1 + M_2)}{(3a)^2} = \boxed{\frac{Gm(M_1 + M_2)}{9a^2}}$$

(*b*) At $r = 1.9a$, g due to M_2 is zero and:

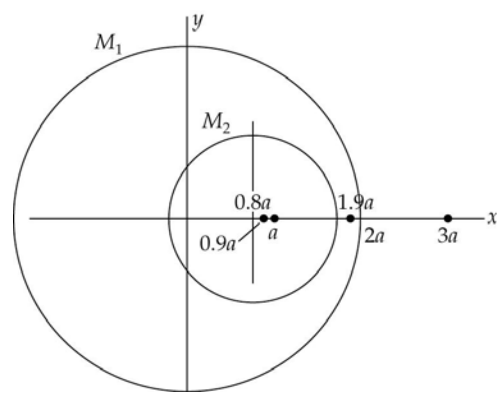
$$F_g(1.9a) = m\frac{GM_1}{(1.9a)^2} = \boxed{\frac{GmM_1}{3.61a^2}}$$

(*c*) At $r = 0.9a$, $g = 0$ and:

$$F_g(0.9a) = \boxed{0}$$

74 •• The inner spherical shell in Problem 73 is shifted so that its center is now on the x axis at $x = 0.8a$. What is the magnitude of the gravitational force on a particle of point mass m located on the x axis at (*a*) $x = 3a$, (*b*) $x = 1.9a$, (*c*) $x = 0.9a$?

Picture the Problem The configuration is shown on the right. The centers of the spheres are indicated by the center-lines. The x coordinates of the mass m for Parts (*a*), (*b*), and (*c*) are indicated along the x axis. The magnitude of the gravitational force is $F_g = mg$ where g inside a spherical shell is zero and outside is given by $g = \dfrac{GM}{r^2}$.



(*a*) Express the gravitational force acting on the object whose mass is m:

$$F_g = m(g_{1x} + g_{2x}) \qquad (1)$$

Find g_{1x} at $x = 3a$:

$$g_{1x}(3a) = \frac{GM_1}{(3a)^2} = \frac{GM_1}{9a^2}$$

Find g_{2x} at $x = 3a$:

$$g_{2x}(3a) = \frac{GM_2}{(3a - 0.8a)^2} = \frac{GM_2}{4.84a^2}$$

Substitute for $g_{1x}(3a)$ and $g_{2x}(3a)$ in equation (1) and simplify to obtain:

$$F(3a) = m\left(\frac{GM_1}{9a^2} + \frac{GM_2}{4.84a^2}\right)$$
$$= \boxed{\frac{Gm}{a^2}\left(\frac{M_1}{9} + \frac{M_2}{4.84}\right)}$$

(*b*) Find g_{2x} at $x = 1.9a$:

$$g_{2x}(1.9a) = \frac{GM_2}{(1.9a - 0.8a)^2}$$
$$= \frac{GM_2}{1.21a^2}$$

Find g_{1x} at $x = 1.9a$:

$$g_{1x}(1.9a) = 0$$

Substitute for $g_{1x}(1.9a)$ and $g_{2x}(1.9a)$ and simplify to obtain:

$$F(1.9a) = mg = \boxed{\frac{GmM_2}{1.21a^2}}$$

(*c*) At $x = 0.9a$, $g_{1x} = g_{2x} = 0$ and:

$$F(0.9a) = \boxed{0}$$

75 •• [SSM] Suppose you are standing on a spring scale in an elevator that is descending at constant speed in a mine shaft located on the equator. Model Earth as a homogeneous sphere. (*a*) Show that the force on you due to Earth's gravity alone is proportional to your distance from the center of the planet. (*b*) Assume that the mine shaft located on the equator and is vertical. Do not neglect Earth's rotational motion. Show that the reading on the spring scale is proportional to your distance from the center of the planet.

Picture the Problem There are two forces acting on you as you descend in the elevator and are at a distance *r* from the center of Earth; an upward normal force (F_N) exerted by the scale, and a downward gravitational force (mg) exerted by Earth. Because you are in equilibrium (you are descending at constant speed) under the influence of these forces, the normal force exerted by the scale is equal in magnitude to the gravitational force acting on you. We can use Newton's law of gravity to express this gravitational force.

(*a*) Express the force of gravity acting on you when you are a distance *r* from the center of Earth:

$$F_g = \frac{GM(r)m}{r^2} \qquad (1)$$

where $M(r)$ is the mass of Earth enclosed within the radius *r*: that is, loser to the center of Earth than your position.

Using the definition of density, express the density of Earth between you and the center of Earth and the density of Earth as a whole:

$$\rho = \frac{M(r)}{V(r)} = \frac{M(r)}{\frac{4}{3}\pi r^3}$$

The density of Earth is also given by:

$$\rho = \frac{M_\mathrm{E}}{V_\mathrm{E}} = \frac{M_\mathrm{E}}{\frac{4}{3}\pi R^3}$$

Equating these two expressions for ρ and solving for $M(r)$ yields:

$$M(r) = M_\mathrm{E}\left(\frac{r}{R}\right)^3$$

Substitute for $M(r)$ in equation (1) and simplify to obtain:

$$F_g = \frac{GM_\mathrm{E}\left(\frac{r}{R}\right)^3 m}{r^2} = \frac{GM_\mathrm{E}m}{R^2}\frac{r}{R} \qquad (2)$$

Apply Newton's law of gravity to yourself at the surface of Earth to obtain:

$$mg = \frac{GM_\mathrm{E}m}{R^2} \Rightarrow g = \frac{GM_\mathrm{E}}{R^2}$$

where g is the magnitude of the gravitational field at the surface of Earth.

Substitute for g in equation (2) to obtain:

$$F_g = \boxed{\left(\frac{mg}{R}\right)r}$$

That is, the force of gravity on you is proportional to your distance from the center of Earth.

(*b*) Apply Newton's second law to your body to obtain:

$$F_\mathrm{N} - mg\frac{r}{R} = -mr\omega^2$$

where the net force $\left(-mr\omega^2\right)$, directed toward the center of Earth, is the centripetal force acting on your body.

Solving for F_N yields:

$$F_\mathrm{N} = \left(\frac{mg}{R}\right)r - mr\omega^2$$

Note that this equation tells us that your effective weight increases linearly with distance from the center of Earth. However, due just to the effect of rotation, as you approach the center the centripetal force decreases linearly and, doing so, increases your effective weight.

76 •• Suppose Earth were a nonrotating uniform sphere. As a reward for earning the highest lab grade, your physics professor chooses your laboratory team to participate in a gravitational experiment at a deep mine on the equator. This mine has an elevator shaft going 15.0 km into Earth. Before making the measurement, you are asked to predict the decrease in the weight of a team member, who weighs 800 N at the surface of Earth, when she is at the bottom of the shaft. The density of Earth's crust actually increases with depth. Is your answer higher or lower than the actual experimental result?

Picture the Problem We can find the loss in weight of your team member at this depth by taking the difference between her weight at the surface of Earth and her weight at a depth d = 15.0 km. To find the gravitational field at depth d, we'll use its definition and the mass of Earth that is between the bottom of the shaft and the center of Earth. We'll assume (incorrectly) that the density of Earth is constant.

The loss in weight of a team member is given by:

$$\Delta w = w(R_E) - w(R) \quad (1)$$

The mass M inside $R = R_E - d$ is given by:

$$M = \rho V = \tfrac{4}{3}\rho\pi(R_E - d)^3$$

Relate the mass of Earth to its density and volume:

$$M_E = \rho V_E = \tfrac{4}{3}\rho\pi R_E^3$$

Divide the first of these equations by the second to obtain:

$$\frac{M}{M_E} = \frac{\tfrac{4}{3}\rho\pi(R_E - d)^3}{\tfrac{4}{3}\rho\pi R_E^3} = \frac{(R_E - d)^3}{R_E^3}$$

Solving for M yields:

$$M = M_E\frac{(R_E - d)^3}{R_E^3}$$

Express the gravitational field at $R = R_E - d$:

$$g = \frac{GM}{R^2} = \frac{GM_E(R_E - d)^3}{(R_E - d)^2 R_E^3} = \frac{GM_E(R_E - d)}{R_E^3} \quad (2)$$

Express the gravitational field at $R = R_E$:

$$g_E = \frac{GM_E}{R_E^2} \quad (3)$$

Divide equation (2) by equation (3) to obtain:

$$\frac{g}{g_E}=\frac{\dfrac{GM_E(R_E-d)}{R_E^3}}{\dfrac{GM_E}{R_E^2}}=\frac{R_E-d}{R_E}$$

Solving for g yields:

$$g=\frac{R_E-d}{R_E}g_E$$

The weight of the student at $R=R_E-d$ is given by:

$$w(R)=mg(R)=\frac{R_E-d}{R_E}mg_E$$
$$=\left(1-\frac{d}{\mathrm{R}_E}\right)mg_E$$

Substitute for $w(R)$ in equation (1) and simplify to obtain:

$$\Delta w=mg_E-\left(1-\frac{d}{\mathrm{R}_E}\right)mg_E=\frac{mg_E d}{R_E}$$

Substitute numerical values and evaluate Δw:

$$\Delta w=\frac{(800\,\mathrm{N})(15.0\,\mathrm{km})}{6370\,\mathrm{km}}=\boxed{1.88\,\mathrm{N}}$$

If Earth's crustal density actually increased with depth, this increase with depth would partially compensate for the decrease in the fraction of Earth's mass between a descending team member and the center of Earth; with the result that the loss in weight would be lower than the actual experimental result.

77 •• [SSM] A solid sphere of radius R has its center at the origin. It has a uniform mass density ρ_0, except that there is a spherical cavity in it of radius $r=\frac{1}{2}R$ centered at $x=\frac{1}{2}R$ as in Figure 11-27. Find the gravitational field at points on the x axis for $|x|>R$. *Hint: The cavity may be thought of as a sphere of mass $m=(4/3)\pi r^3\rho_0$ plus a sphere of "negative" mass –m.*

Picture the Problem We can use the hint to find the gravitational field along the x axis.

Using the hint, express $g(x)$:

$$g(x)=g_{\text{solid sphere}}+g_{\text{hollow sphere}}$$

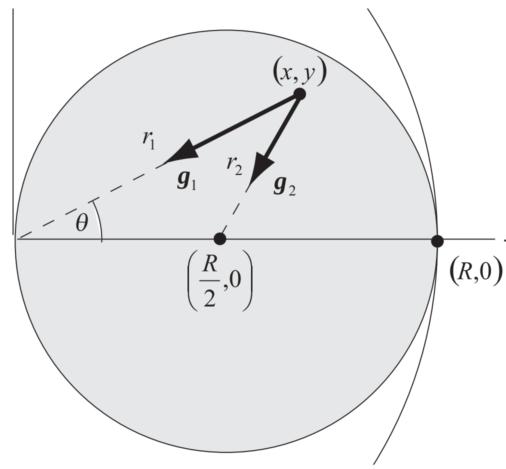
Substitute for $g_{\text{solid sphere}}$ and $g_{\text{hollow sphere}}$ and simplify to obtain:

$$g(x) = \frac{GM_{\text{solid sphere}}}{x^2} + \frac{GM_{\text{hollow sphere}}}{\left(x - \frac{1}{2}R\right)^2} = \frac{G\rho_0\left(\frac{4}{3}\pi R^3\right)}{x^2} + \frac{G\rho_0\left[-\frac{4}{3}\pi\left(\frac{1}{2}R\right)^3\right]}{\left(x - \frac{1}{2}R\right)^2}$$

$$= \boxed{G\left(\frac{4\pi\rho_0 R^3}{3}\right)\left[\frac{1}{x^2} - \frac{1}{8\left(x - \frac{1}{2}R\right)^2}\right]}$$

78 ••• For the sphere with the cavity in Problem 77, show that the gravitational field is uniform throughout the cavity, and find its magnitude and direction there.

Picture the Problem The diagram shows the portion of the solid sphere in which the hollow sphere is embedded. $\vec{g}_1$ is the field due to the solid sphere of radius R and density ρ_0 and $\vec{g}_2$ is the field due to the sphere of radius $\frac{1}{2}\boldsymbol{R}$ and negative density ρ_0 centered at $\frac{1}{2}\boldsymbol{R}$. We can find the resultant field by adding the x and y components of $\vec{g}_1$ and $\vec{g}_2$.



Use its definition to express $|\vec{g}_1|$:

$$|\vec{g}_1| = \frac{F_g}{m}$$

Substitute for the gravitational force to obtain:

$$|\vec{g}_1| = \frac{\frac{GMm}{r_1^2}}{m} = \frac{GM}{r_1^2}$$

Substituting the product of its density and volume for the mass of the sphere and simplifying yields:

$$|\vec{g}_1| = \frac{G\rho_0 V}{r_1^2} = \frac{4\pi\rho_0 r_1^3 G}{3r_1^2} = \frac{4\pi\rho_0 r_1 G}{3}$$

Find the x and y components of $\vec{g}_1$:

$$g_{1x} = -g_1 \cos\theta = -g_1\left(\frac{x}{r_1}\right) = -\frac{4\pi\rho_0 Gx}{3}$$

and

$$g_{1y} = -g_1 \sin\theta = -g_1\left(\frac{y}{r_1}\right) = -\frac{4\pi\rho_0 Gy}{3}$$

where the negative signs indicate that the field points inward.

Proceed similarly to express $\left|\vec{g}_2\right|$:

$$\left|\vec{\mathbf{g}}_2\right| = \frac{4\pi\rho_0 r_2 G}{3}$$

Express the x and y components of $\vec{g}_2$:

$$g_{2x} = g_2\left(\frac{x - \frac{1}{2}R}{r_2}\right) = \frac{4\pi\rho_0 G\left(x - \frac{1}{2}R\right)}{3}$$

and

$$g_{2y} = g_2\left(\frac{y}{r_2}\right) = \frac{4\pi\rho_0 Gy}{3}$$

Add the x components and simplify to obtain the x component of the resultant field:

$$\begin{aligned} g_x &= g_{1x} + g_{2x} \\ &= -\frac{4\pi\rho_0 Gx}{3} + \frac{4\pi\rho_0 G\left(x - \frac{1}{2}R\right)}{3} \\ &= -\frac{2\pi\rho_0 GR}{3} \end{aligned}$$

where the negative sign indicates that the field points inward.

Add the y components and simplify to obtain the y component of the resultant field:

$$\begin{aligned} g_y &= g_{1y} + g_{2y} \\ &= -\frac{4\pi\rho_0 Gy}{3} + \frac{4\pi\rho_0 Gy}{3} = 0 \end{aligned}$$

Express $\vec{g}$ in vector form:

$$\vec{g} = g_x\hat{i} + g_y\hat{j} = \boxed{\left(-\frac{2\pi\rho_0 GR}{3}\right)\hat{i} + 0\hat{j}}$$

The magnitude of $\vec{g}$ is:

$$\left|\vec{g}\right| = \sqrt{g_x^2 + g_y^2} = \boxed{\frac{2\pi\rho_0 GR}{3}}$$

79 ••• A straight, smooth tunnel is dug through a uniform spherical planet of mass density ρ_0. The tunnel passes through the center of the planet and is perpendicular to the planet's axis of rotation, which is fixed in space. The planet

rotates with a constant angular speed ω so objects in the tunnel have no apparent weight. Find the required angular speed of the planet ω.

Picture the Problem The gravitational field will exert an inward radial force on the objects in the tunnel. We can relate this force to the angular speed of the planet by using Newton's second law of motion.

Letting r be the distance from the objects to the center of the planet, use Newton's second law to relate the gravitational force acting on the objects to their angular speed:

$$F_{\text{net}} = F_{\text{g}} = mr\omega^2$$

or

$$mg = mr\omega^2 \Rightarrow \omega = \sqrt{\frac{g}{r}} \qquad (1)$$

Use its definition to express g:

$$g = \frac{F_{\text{g}}}{m}$$

Substitute for F_{g} to obtain:

$$g = \frac{F_{\text{g}}}{m} = \frac{\frac{GMm}{r^2}}{m} = \frac{GM}{r^2}$$

Substituting the product of its density and volume for the mass of planet and simplifying yields:

$$g = \frac{G\rho_0 V}{r^2} = \frac{4\pi\rho_0 r^3 G}{3r^2} = \frac{4\pi\rho_0 rG}{3}$$

Substituting for g in equation (1) and simplifying yields:

$$\omega = \sqrt{\frac{\frac{4\pi\rho_0 rG}{3}}{r}} = \boxed{\sqrt{\frac{4\pi\rho_0 G}{3}}}$$

80 ••• The density of a sphere is given by $\rho(r) = C/r$. The sphere has a radius of 5.0 m and a mass of 1.0×10^{11} kg. (*a*) Determine the constant C. (*b*) Obtain expressions for the gravitational field for the regions (1) $r > 5.0$ m and (2) $r < 5.0$ m.

Picture the Problem Because we're given the mass of the sphere, we can find C by expressing the mass of the sphere in terms of C. We can use its definition to find the gravitational field of the sphere both inside and outside its surface.

(*a*) Express the mass of a differential element of the sphere:

$$dm = \rho\, dV = \rho\left(4\pi r^2 dr\right)$$

Integrate to express the mass of the sphere in terms of C:

$$M = 4\pi C \int_0^{5.0\,\text{m}} r dr = (50\,\text{m}^2)\pi C$$

Solving for C yields:

$$C = \frac{M}{(50\,\text{m}^2)\pi}$$

Substitute numerical values and evaluate C:

$$C = \frac{1.0\times10^{11}\,\text{kg}}{(50\,\text{m}^2)\pi} = 6.37\times10^{8}\,\text{kg/m}^2$$

$$= \boxed{6.4\times10^{8}\,\text{kg/m}^2}$$

(b) Use its definition to express the gravitational field of the sphere at a distance from its center greater than its radius:

$$g = \frac{GM}{r^2}$$

(1) For $r > 5.0$ m:

$$g(r > 5.0\,\text{m}) = \frac{(6.673\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(1.0\times10^{11}\,\text{kg})}{r^2} = \boxed{\frac{6.7\,\text{N}\cdot\text{m}^2/\text{kg}}{r^2}}$$

Use its definition to express the gravitational field of the sphere at a distance from its center less than its radius:

$$g = G\frac{\int_0^r 4\pi r^2 \rho\, dr}{r^2} = G\frac{\int_0^r 4\pi r^2 \frac{C}{r}\, dr}{r^2}$$

$$= G\frac{4\pi C\int_0^r r\, dr}{r^2} = 2\pi GC$$

(2) For $r < 5.0$ m:

$$g(r < 5.0\,\text{m}) = 2\pi(6.673\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(6.37\times10^{8}\,\text{kg/m}^2) = \boxed{0.27\,\text{N/kg}}$$

81 ••• [SSM] A small diameter hole is drilled into the sphere of Problem 80 toward the center of the sphere to a depth of 2.0 m below the sphere's surface. A small mass is dropped from the surface into the hole. Determine the speed of the small mass as it strikes the bottom of the hole.

Picture the Problem We can use conservation of energy to relate the work done by the gravitational field to the speed of the small object as it strikes the bottom of the hole. Because we're given the mass of the sphere, we can find C by expressing the mass of the sphere in terms of C. We can then use the definition of

the gravitational field to find the gravitational field of the sphere inside its surface. The work done by the field equals the negative of the change in the potential energy of the system as the small object falls in the hole.

Use conservation of energy to relate the work done by the gravitational field to the speed of the small object as it strikes the bottom of the hole:

$$K_f - K_i + \Delta U = 0$$

or, because $K_i = 0$ and $W = -\Delta U$,

$$W = \tfrac{1}{2}mv^2 \Rightarrow v = \sqrt{\frac{2W}{m}} \qquad (1)$$

where v is the speed with which the object strikes the bottom of the hole and W is the work done by the gravitational field.

Express the mass of a differential element of the sphere:

$$dm = \rho\, dV = \rho\left(4\pi r^2 dr\right)$$

Integrate to express the mass of the sphere in terms of C:

$$M = 4\pi C \int_0^{5.0\,\text{m}} r dr = \left(50\,\text{m}^2\right)\pi C$$

Solving for C yields:

$$C = \frac{M}{\left(50\,\text{m}^2\right)\pi}$$

Substitute numerical values and evaluate C:

$$C = \frac{1.0\times10^{11}\ \text{kg}}{\left(50\,\text{m}^2\right)\pi} = 6.37\times10^{8}\ \text{kg/m}^2$$

Use its definition to express the gravitational field of the sphere at a distance from its center less than its radius:

$$g = \frac{F_g}{m} = \frac{GM}{r^2} = G\frac{\int_0^r 4\pi r^2 \rho\, dr}{r^2} = G\frac{\int_0^r 4\pi r^2 \frac{C}{r} dr}{r^2} = G\frac{4\pi C\int_0^r r\, dr}{r^2} = 2\pi GC$$

Express the work done on the small object by the gravitational force acting on it:

$$W = -\int_{5.0\,\text{m}}^{3.0\,\text{m}} mgdr = (2\,\text{m})mg$$

Substitute in equation (1) and simplify to obtain:

$$v = \sqrt{\frac{2(2.0\,\text{m})m(2\pi GC)}{m}} = \sqrt{(8.0\,\text{m})\pi GC}$$

Substitute numerical values and evaluate v:

$$v=\sqrt{(8.0\,\text{m})\pi\left(6.673\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(6.37\times10^{8}\,\text{kg/m}^2\right)}=\boxed{1.0\,\text{m/s}}$$

82 ••• As a geologist for a mining company, you are working on a method for determining possible locations of underground ore deposits. Assume that where the company owns land the crust of Earth is 40.0 km thick and has a density of about 3000 kg/m^3. Suppose a spherical deposit of heavy metals with a density of 8000 kg/m^3 and radius of 1000 m was centered 2000 m below the surface. You propose to detect it by determining its affect on the local surface value of g. Find $\Delta g/g$ at the surface directly above this deposit, where Δg is the increase in the gravitational field due to the deposit.

Picture the Problem The spherical deposit of heavy metals will increase the gravitational field at the surface of Earth. We can express this increase in terms of the difference in densities of the deposit and Earth and then form the quotient $\Delta g/g$.

Express Δg due to the spherical deposit:

$$\Delta g=\frac{G\Delta M}{r^2}\qquad(1)$$

Express the mass of the spherical deposit:

$$M=\Delta\rho V=\Delta\rho\left(\tfrac{4}{3}\pi R^3\right)=\tfrac{4}{3}\pi\,\Delta\rho\,R^3$$

Substitute in equation (1):

$$\Delta g=\frac{\frac{4}{3}G\pi\,\Delta\rho\,R^3}{r^2}$$

Express $\Delta g/g$:

$$\frac{\Delta g}{g}=\frac{\dfrac{\frac{4}{3}G\pi\,\Delta\rho\,R^3}{r^2}}{g}=\frac{\frac{4}{3}G\pi\,\Delta\rho\,R^3}{gr^2}$$

Substitute numerical values and evaluate $\Delta g/g$:

$$\frac{\Delta g}{g}=\frac{\frac{4}{3}\pi\left(6.673\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(5000\,\text{kg/m}^3\right)(1000\,\text{m})^3}{(9.81\,\text{N/kg})(2000\,\text{m})^2}=\boxed{3.56\times10^{-5}}$$

83 ••• **[SSM]** Two identical spherical cavities are made in a lead sphere of radius R. The cavities each have a radius $R/2$. They touch the outside surface of the sphere and its center as in Figure 11-28. The mass of a solid uniform lead sphere of radius R is M. Find the force of attraction on a point particle of mass m located at a distance d from the center of the lead sphere.

Picture the Problem The force of attraction of the small sphere of mass m to the lead sphere of mass M is the sum of the forces due to the solid sphere ($\vec{F}_S$) and the cavities ($\vec{F}_C$) of negative mass.

Express the force of attraction:

$$\vec{F} = \vec{F}_S + \vec{F}_C \quad (1)$$

Use the law of gravity to express the force due to the solid sphere:

$$\vec{F}_S = -\frac{GMm}{d^2}\hat{i}$$

Express the magnitude of the force acting on the small sphere due to one cavity:

$$F_C = \frac{GM'm}{d^2 + \left(\frac{R}{2}\right)^2}$$

where M' is the negative mass of a cavity.

Relate the negative mass of a cavity to the mass of the sphere before hollowing:

$$M' = -\rho V = -\rho\left[\tfrac{4}{3}\pi\left(\frac{R}{2}\right)^3\right] = -\tfrac{1}{8}\left(\tfrac{4}{3}\pi\rho R^3\right) = -\tfrac{1}{8}M$$

Letting θ be the angle between the x axis and the line joining the center of the small sphere to the center of either cavity, use the law of gravity to express the force due to the two cavities:

$$\vec{F}_C = 2\frac{GMm}{8\left(d^2 + \frac{R^2}{4}\right)}\cos\theta\,\hat{i}$$

because, by symmetry, the y components add to zero.

Use the figure to express $\cos\theta$:

$$\cos\theta = \frac{d}{\sqrt{d^2 + \frac{R^2}{4}}}$$

Substitute for $\cos\theta$ and simplify to obtain:

$$\vec{F}_C = \frac{GMm}{4\left(d^2 + \frac{R^2}{4}\right)}\frac{d}{\sqrt{d^2 + \frac{R^2}{4}}}\hat{i} = \frac{GMmd}{4\left(d^2 + \frac{R^2}{4}\right)^{3/2}}\hat{i}$$

Substitute in equation (1) and simplify:

$$\vec{F} = -\frac{GMm}{d^2}\hat{i} + \frac{GMmd}{4\left(d^2 + \frac{R^2}{4}\right)^{3/2}}\hat{i}$$

$$= \boxed{-\frac{GMm}{d^2}\left[1 - \frac{\frac{d^3}{4}}{\left\{d^2 + \frac{R^2}{4}\right\}^{3/2}}\right]\hat{i}}$$

84 ••• A globular cluster is a roughly spherical collection of up to millions of stars bound together by the force of gravity. Astronomers can measure the velocities of stars in the cluster to study its composition and to get an idea of the mass distribution within the cluster. Assuming that all of the stars have about the same mass and are distributed uniformly within the cluster, show that the mean speed of a star in a circular orbit around the center of the cluster should increase linearly with its distance from the center.

Picture the Problem Let R be the size of the cluster, and N the total number of stars in it. We can apply Newton's law of gravity and the second law of motion to relate the net force (which depends on the number of stars $N(r)$ in a sphere whose radius is equal to the distance between the star of interest and the center of the cluster) acting on a star at a distance r from the center of the cluster to its speed. We can use the definition of density, in conjunction with the assumption of uniform distribution of the starts within the cluster, to find $N(r)$ and, ultimately, express the orbital speed v of a star in terms of the total mass of the cluster.

Using Newton's law of gravity and second law, express the force acting on a star at a distance r from the center of the cluster:

$$F(r) = \frac{GN(r)M^2}{r^2} = M\frac{v^2}{r} \qquad (1)$$

where $N(r)$ is the number of stars within a distance r of the center of the cluster and M is the mass of an individual star.

Using the uniform distribution assumption and the definition of density, relate the number of stars $N(r)$ within a distance r of the center of the cluster to the total number N of stars in the cluster:

$$\rho = \frac{N(r)M}{\frac{4}{3}\pi r^3} = \frac{NM}{\frac{4}{3}\pi R^3} \Rightarrow N(r) = N\frac{r^3}{R^3}$$

Substitute for $N(r)$ in equation (1) to obtain:

$$\frac{GNM^2}{r^2}\frac{r^3}{R^3} = M\frac{v^2}{r}$$

Solving for v yields:

$$v = r\sqrt{\frac{GNM}{R^3}} \Rightarrow v \propto r$$

The mean speed v of a star in a circular orbit about the center of the cluster increases linearly with distance r from the center.

General Problems

85 • The mean distance of Pluto from the Sun is 39.5 AU. Calculate the period of Pluto′s orbital motion.

Picture the Problem We can use Kepler's third law to relate Pluto's period to its mean distance from the Sun.

Using Kepler's third law, relate the period of Pluto to its mean distance from the Sun:

$$T_{\text{Pluto}}^2 = Cr_{\text{Pluto}}^3 \Rightarrow T_{\text{Pluto}} = \sqrt{Cr_{\text{Pluto}}^3}$$

where $C = \frac{4\pi^2}{GM_{\text{s}}} = 2.973\times10^{-19}\ \text{s}^2/\text{m}^3$.

Substitute numerical values and evaluate T_{Pluto}:

$$T_{\text{Pluto}} = \sqrt{\left(2.973\times10^{-19}\ \text{s}^2/\text{m}^3\right)\left(39.5\,\text{AU}\times\frac{1.50\times10^{11}\ \text{m}}{\text{AU}}\right)^3}$$
$$= 7.864\times10^9\ \text{s}\times\frac{1\,\text{h}}{3600\,\text{s}}\times\frac{1\,\text{d}}{24\,\text{h}}\times\frac{1\,\text{y}}{365.25\,\text{d}} = \boxed{249\,\text{y}}$$

86 • Calculate the mass of Earth using the known values of G, g, and R_{E}.

Picture the Problem Consider an object of mass m at the surface of Earth. We can relate the weight of this object to the gravitational field of Earth and to the mass of Earth.

Using Newton's second law, relate the weight of an object at the surface of Earth to the gravitational force acting on it:

$$w = mg = \frac{GM_{\text{E}}m}{R_{\text{E}}^2} \Rightarrow M_{\text{E}} = \frac{gR_{\text{E}}^2}{G}$$

Substitute numerical values and evaluate M_{E}:

$$M_{\text{E}} = \frac{(9.81\,\text{N/kg})(6.37\times10^6\,\text{m})^2}{6.673\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2} = \boxed{5.97\times10^{24}\,\text{kg}}$$

87 •• The force exerted by Earth on a particle of mass m a distance r ($r > R_{\text{E}}$) from the center of Earth has the magnitude mgR_{E}^2/r^2, where $g = GM_{\text{E}}/R_{\text{E}}^2$. (*a*) Calculate the work you must do to move the particle from distance r_1 to distance r_2. (*b*) Show that when $r_1 = R_{\text{E}}$ and $r_2 = R_{\text{E}} + h$, the result can be written as $W = mgR_{\text{E}}^2\left[(1/R_{\text{E}}) - 1/(R_{\text{E}}+h)\right]$. (*c*) Show that when $h \ll R_{\text{E}}$, the work is given approximately by $W = mgh$.

Picture the Problem The work you must do against gravity to move the particle from a distance r_1 to r_2 is the negative of the change in the particle's gravitational potential energy.

(*a*) Relate the work you must do to the change in the gravitational potential energy of Earth-particle system:

$$W = -\Delta U = -\int_{r_1}^{r_2}\vec{F}_{\text{g}}\cdot d\vec{r} = -\int_{r_1}^{r_2}F_{\text{g}}dr(\cos180°) = \int_{r_1}^{r_2}F_{\text{g}}dr$$

Substitute for F_{g} and evaluate the integral to obtain:

$$W = GM_{\text{E}}m\int_{r_1}^{r_2}\frac{dr}{r^2} = -GM_{\text{E}}m\left(\frac{1}{r_2}-\frac{1}{r_1}\right) = \boxed{GM_{\text{E}}m\left(\frac{1}{r_1}-\frac{1}{r_2}\right)}$$

(*b*) Substitute gR_{E}^2 for GM_{E}, R_{E} for r_1, and $R_{\text{E}} + h$ for r_2 to obtain:

$$W = \boxed{mgR_{\text{E}}^2\left(\frac{1}{R_{\text{E}}}-\frac{1}{R_{\text{E}}+h}\right)} \quad (1)$$

(c) Rewrite equation (1) with a common denominator and simplify to obtain:

$$W = mgR_E^2\left(\frac{R_E + h - R_E}{R_E(R_E + h)}\right) = mgh\left(\frac{R_E}{R_E + h}\right) = mgh\left(\frac{1}{1+\dfrac{h}{R_E}}\right) \approx \boxed{mgh}$$

provided $h << R_E$.

88 •• The average density of the moon is $\rho = 3340\ \mathrm{kg/m^3}$. Find the minimum possible period T of a spacecraft orbiting the moon.

Picture the Problem Let m represent the mass of the spacecraft. From Kepler's third law we know that its period will be a minimum when it is in orbit just above the surface of the moon. We'll use Newton's second law to relate the angular speed of the spacecraft to the gravitational force acting on it.

Relate the period of the spacecraft to its angular speed:

$$T = \frac{2\pi}{\omega} \qquad (1)$$

Using Newton's second law, relate the gravitational force acting on the spacecraft when it is in orbit at the surface of the moon to the angular speed of the spacecraft:

$$\sum F_{\text{radial}} = \frac{GM_M m}{R_M^2} = mR_M\omega^2$$

Solving for ω and simplifying yields:

$$\omega = \sqrt{\frac{GM_M}{R_M^3}} = \sqrt{\frac{G\left(\frac{4}{3}\pi\rho R_M^3\right)}{R_M^3}} = \sqrt{\tfrac{4}{3}G\pi\rho}$$

Substitute for ω in equation (1) and simplify to obtain:

$$T_{\min} = \frac{2\pi}{\sqrt{\frac{4}{3}G\pi\rho}} = \sqrt{\frac{3\pi}{\rho G}}$$

Substitute numerical values and evaluate $T_{\min}$:

$$T_{\min} = \sqrt{\frac{3\pi}{\left(6.673\times10^{-11}\ \mathrm{N\cdot m^2/kg^2}\right)\left(3340\ \mathrm{kg/m^3}\right)}} = 6503\ \mathrm{s} = \boxed{1\ \mathrm{h}\ 48\ \mathrm{min}}$$

89 •• **[SSM]** A *neutron star* is a highly condensed remnant of a massive star in the last phase of its evolution. It is composed of neutrons (hence the name) because the star's gravitational force causes electrons and protons to "coalesce" into the neutrons. Suppose at the end of its current phase, the Sun collapsed into a neutron star (it can't in actuality because it does not have enough mass) of radius 12.0 km, without losing any mass in the process. (*a*) Calculate the ratio of the gravitational acceleration at the surface of the Sun following its collapse compared to its value at the surface of the Sun today. (*b*) Calculate the ratio of the escape speed from the surface of the neutron-Sun to its value today.

Picture the Problem We can apply Newton's second law and the law of gravity to an object of mass *m* at the surface of the Sun and the neutron-Sun to find the ratio of the gravitational accelerations at their surfaces. Similarly, we can express the ratio of the corresponding expressions for the escape speeds from the two suns to determine their ratio.

(*a*) Express the gravitational force acting on an object of mass *m* at the surface of the Sun:

$$F_g = ma_g = \frac{GM_{Sun}m}{R_{Sun}^2}$$

Solving for a_g yields:

$$a_g = \frac{GM_{Sun}}{R_{Sun}^2} \qquad (1)$$

The gravitational force acting on an object of mass *m* at the surface of a neutron-Sun is:

$$F_g = ma'_g = \frac{GM_{neutron\text{-}Sun}m}{R_{neutron\text{-}Sun}^2}$$

Solving for a'_g yields:

$$a'_g = \frac{GM_{neutron\text{-}Sun}}{R_{neutron\text{-}Sun}^2} \qquad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{a'_g}{a_g} = \frac{\dfrac{GM_{neutron\text{-}Sun}}{R_{neutron\text{-}Sun}^2}}{\dfrac{GM_{Sun}}{R_{Sun}^2}} = \frac{\dfrac{M_{neutron\text{-}Sun}}{R_{neutron\text{-}Sun}^2}}{\dfrac{M_{Sun}}{R_{Sun}^2}}$$

Because $M_{neutron\text{-}Sun} = M_{Sun}$:

$$\frac{a'_g}{a_g} = \frac{R_{Sun}^2}{R_{neutron\text{-}Sun}^2}$$

Substitute numerical values and evaluate the ratio a'_g/a_g:

$$\frac{a'_g}{a_g} = \left(\frac{6.96\times10^8\ \text{m}}{12.0\times10^3\ \text{m}}\right)^2 = \boxed{3.36\times10^9}$$

(*b*) The escape speed from the neutron-Sun is given by:

$$v'_e = \sqrt{\frac{GM_{\text{neutron-Sun}}}{R_{\text{neutron-Sun}}}}$$

The escape speed from the Sun is given by:

$$v_e = \sqrt{\frac{GM_{\text{Sun}}}{R_{\text{Sun}}}}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{v'_e}{v_e} = \sqrt{\frac{R_{\text{Sun}}}{R_{\text{neutron-Sun}}}}$$

Substitute numerical values and evaluate v'_e/v_e:

$$\frac{v'_e}{v_e} = \sqrt{\frac{6.96\times10^8\ \text{m}}{12.0\times10^3\ \text{m}}} = \boxed{241}$$

90 •• Suppose the Sun could collapse into a neutron star of radius 12.0 km, as in Problem 89. Your research team is in charge of sending a probe from Earth to study the transformed Sun, and the probe needs to end up in a circular orbit 4500 km from the neutron-Sun's center. (*a*) Calculate the orbital speed of the probe. (*b*) Later on, plans call for construction of a permanent spaceport in that same orbit. To transport equipment and supplies, scientists on Earth need you to determine the escape speed for rockets launched from the spaceport (relative to the spaceport) in the direction of the spaceport's orbital velocity at takeoff time. What is that speed, and how does it compare to the escape speed at the surface of Earth?

Picture the Problem We can apply Newton's law law to the probe orbiting the Sun to determine its orbital speed. Using the escape-speed equation will allow us to find the escape speed for rockets launched from the spaceport.

(*a*) Apply Newton's second law to the probe of mass *m* in orbit about the Sun:

$$\sum F_{\text{radial}} = \frac{GmM_{\text{Sun}}}{r^2} = m\frac{v_{\text{orbital}}^2}{r}$$

where *r* is the orbital radius.

Solving for v_{orbital} yields:

$$v_{\text{orbital}} = \sqrt{\frac{GM_{\text{Sun}}}{r}}$$

Substitute numerical values and evaluate v_{orbital}:

$$v_{\text{orbital}} = \sqrt{\frac{\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(1.99\times10^{30}\ \text{kg}\right)}{4.50\times10^6\ \text{m}}} = 5.432\times10^6\ \text{m/s}$$

$$= \boxed{5.43\times10^6\ \text{m/s}}$$

(*b*) The escape speed (relative to the spaceport) for rockets launched from the spaceport is given by:

$$v_{\substack{\text{rel to}\\\text{spaceport}}} = v_e - v_{\text{orbital}} \quad (1)$$

The escape speed at a distance r from the center of the neutron-Sun is given by:

$$v_e = \sqrt{\frac{2GM_{\text{neutron-Sun}}}{r}} = \sqrt{2}\sqrt{\frac{GM_{\text{neutron-Sun}}}{r}} = \sqrt{2}v_{\text{orbital}}$$

Substituting for v_e in equation (1) yields:

$$v_{\substack{\text{rel to}\\\text{spaceport}}} = \sqrt{2}v_{\text{orbital}} - v_{\text{orbital}} = \left(\sqrt{2}-1\right)v_{\text{orbital}}$$

Substitute numerical values and evaluate $v_{\substack{\text{rel to}\\\text{spaceport}}}$:

$$v_{\substack{\text{rel to}\\\text{spaceport}}} = \left(\sqrt{2}-1\right)\left(5.431\times10^{6}\ \text{m/s}\right) = \boxed{2.25\times10^{6}\ \text{m/s}}$$

Express the ratio of $v_{\substack{\text{rel to}\\\text{spaceport}}}$ to $v_{\text{e,Earth}}$:

$$\frac{v_{\substack{\text{rel to}\\\text{spaceport}}}}{v_{\text{e,Earth}}} = \frac{2.25\times10^{6}\ \text{m/s}}{11.2\ \text{km/s}} \approx \boxed{201}$$

91 •• A satellite is circling the moon (radius 1700 km) close to the surface at a speed *v*. A projectile is launched from the moon vertically up at the same initial speed *v*. How high will it rise?

Picture the Problem We can use conservation of energy to establish a relationship between the height h to which the projectile will rise and its initial speed. The application of Newton's second law will relate the orbital speed, which is equal to the initial speed of the projectile, to the mass and radius of the moon.

Use conservation of energy to relate the initial energies of the projectile to its final energy:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = 0$,

$$-\tfrac{1}{2}mv^2 - \frac{GM_{\text{moon}}m}{R_{\text{moon}}+h} + \frac{GM_{\text{moon}}m}{R_{\text{moon}}} = 0$$

Solving for h yields:

$$h = R_M\left(\frac{1}{1-\dfrac{v^2R_{\text{moon}}}{2GM_{\text{moon}}}} - 1\right) \quad (1)$$

Use Newton's second law to relate the orbital speed of the satellite to the gravitational force acting on it:

$$\sum F_{\text{radial}} = \frac{GM_{\text{M}}m}{R_{\text{M}}^2} = m\frac{v^2}{R_{\text{M}}}$$

Solve for v^2 to obtain:

$$v^2 = \frac{GM_{\text{M}}}{R_{\text{M}}}$$

Substitute for v^2 in equation (1) and simplify to obtain:

$$h = R_{\text{M}}\left(\frac{1}{1-\frac{1}{2}} - 1\right) = R_{\text{M}} = \boxed{1.70\,\text{Mm}}$$

92 •• *Black holes* are objects whose gravitational field is so strong that not even light can escape. One way of thinking about this is to consider a spherical object whose density is so large that the escape speed at its surface is greater than the speed of light c. If a star's radius is smaller than a value called the *Schwarzchild radius* R_{S}, then the star will be a black hole, that is, light originating from its surface cannot escape. (a) For a non-rotating black hole, the Schwarzchild radius depends only upon the mass of the black hole. Show that it is related to that mass M by $R_{\text{S}} = 2GM/c^2$. (b) Calculate the value of the Schwarzchild radius for a black hole whose mass is ten solar masses.

Picture the Problem We can use the escape-speed equation, with $v_{\text{e}} = c$, to derive the expression for the Schwarzchild radius of a non-rotating black hole.

(a) The escape speed at a distance r from the center of a spherical object of mass M is given by:

$$v_{\text{e}} = \sqrt{\frac{2GM}{r}}$$

Setting $v_{\text{e}} = c$ yields:

$$c = \sqrt{\frac{2GM}{R_{\text{S}}}} \Rightarrow R_{\text{S}} = \boxed{\frac{2GM}{c^2}}$$

(b) For a black hole whose mass is ten solar masses:

$$R_{\text{S}} = \frac{2G(10M_{\text{Sun}})}{c^2} = \frac{20GM_{\text{Sun}}}{c^2}$$

Substitute numerical values and evaluate R_{S}:

$$R_{\text{S}} = \frac{20(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\ \text{kg})}{(2.998\times10^{8}\ \text{m/s})^2} = \boxed{29.5\,\text{km}}$$

93 •• In a binary star system, two stars follow circular orbits about their common center of mass. If the stars have masses m_1 and m_2 and are separated by a distance *r,* show that the period of rotation is related to *r* by $T^2 = \dfrac{4\pi^2 r^3}{G(m_1 + m_2)}$.

Picture the Problem Let the origin of our coordinate system be at the center of mass of the binary star system and let the distances of the stars from their center of mass be r_1 and r_2. The period of rotation is related to the angular speed of the star system and we can use Newton's second law of motion to relate this speed to the separation of the stars.

Relate the square of the period of the motion of the stars to their angular speed:

$$T^2 = \frac{4\pi^2}{\omega^2} \qquad (1)$$

Using Newton's second law, relate the gravitational force acting on the star whose mass is m_2 to the angular speed of the system:

$$\sum F_{\text{radial}} = \frac{Gm_1 m_2}{(r_1 + r_2)^2} = m_2 r_2 \omega^2$$

Solving for ω^2 yields:

$$\omega^2 = \frac{Gm_1}{r_2 (r_1 + r_2)^2} \qquad (2)$$

From the definition of the center of mass we have:

$$m_1 r_1 = m_2 r_2 \qquad (3)$$

where $r = r_1 + r_2 \qquad (4)$

Eliminate r_1 from equations (3) and (4) and solve for r_2 to obtain:

$$r_2 = \frac{r m_1}{m_1 + m_2}$$

Eliminate r_2 from equations (3) and (4) and solve for r_1 to obtain:

$$r_1 = \frac{r m_2}{m_1 + m_2}$$

Substituting for r_1 and r_2 in equation (2) yields:

$$\omega^2 = \frac{G(m_1 + m_2)}{r^3}$$

Finally, substitute for ω^2 in equation (1) and simplify:

$$T^2 = \frac{4\pi^2}{\dfrac{G(m_1 + m_2)}{r^3}} = \boxed{\frac{4\pi^2 r^3}{G(m_1 + m_2)}}$$

94 •• Two particles of masses m_1 and m_2 are released from rest at a large separation distance. Find their speeds v_1 and v_2 when their separation distance is r. The initial separation distance is given as large, but large is a relative term. Relative to what distance is it large?

Picture the Problem Because the two-particle system has zero initial energy and zero initial linear momentum; we can use energy and momentum conservation to obtain simultaneous equations in the variables r, v_1 and v_2. We'll assume that initial separation distance of the particles and their final separation *r is large compared to the size of the particles* so that we can treat them as though they are point particles.

Use conservation of energy to relate the speeds of the particles when their separation distance is r:

$$E_\mathrm{i} = E_\mathrm{f}$$

or

$$0 = \tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2 - \frac{Gm_1m_2}{r} \quad (1)$$

Use conservation of linear momentum to obtain a second relationship between the speeds of the particles and their masses:

$$p_\mathrm{i} = p_\mathrm{f}$$

or

$$0 = m_1v_1 + m_2v_2 \quad (2)$$

Solve equation (2) for v_1 and substitute in equation (1) to obtain:

$$v_2^2\left(m_2 + \frac{m_2^2}{m_1}\right) = \frac{2Gm_1m_2}{r} \quad (3)$$

Solve equation (3) for v_2:

$$v_2 = \boxed{\sqrt{\frac{2Gm_1^2}{r(m_1 + m_2)}}}$$

Solve equation (2) for v_1 and substitute for v_2 to obtain:

$$v_1 = \boxed{\sqrt{\frac{2Gm_2^2}{r(m_1 + m_2)}}}$$

95 •• [SSM] Uranus, the seventh planet in the Solar System, was first observed in 1781 by William Herschel. Its orbit was then analyzed in terms of Kepler's Laws. By the 1840s, observations of Uranus clearly indicated that its true orbit was different from the Keplerian calculation by an amount that could not be accounted for by observational uncertainty. The conclusion was that there must be another influence other than the Sun and the known planets lying inside Uranus's orbit. This influence was hypothesized to be due to an eighth planet, whose predicted orbit was described independently in 1845 by two astronomers: John Adams (no relation to the former president of the United States) and Urbain LeVerrier. In September of 1846, John Galle, searching in the sky at the place

predicted by Adams and LeVerrier, made the first observation of Neptune. Uranus and Neptune are in orbit about the Sun with periods of 84.0 and 164.8 years, respectively. To see the effect that Neptune had on Uranus, determine the ratio of the gravitational force between Neptune and Uranus to that between Uranus and the Sun, when Neptune and Uranus are at their closest approach to one another (i.e. when aligned with the Sun). The masses of the Sun, Uranus, and Neptune are 333,000, 14.5 and 17.1 times that of Earth, respectively.

Picture the Problem We can use the law of gravity and Kepler's third law to express the ratio of the gravitational force between Neptune and Uranus to that between Uranus and the Sun, when Neptune and Uranus are at their closest approach to one another.

The ratio of the gravitational force between Neptune and Uranus to that between Uranus and the Sun, when Neptune and Uranus are at their closest approach to one another is given by:

$$\frac{F_{\text{g,N-U}}}{F_{\text{g,U-S}}}=\frac{\dfrac{GM_{\text{N}}M_{\text{U}}}{(r_{\text{N}}-r_{\text{U}})^2}}{\dfrac{GM_{\text{U}}M_{\text{S}}}{r_{\text{U}}^2}}=\frac{M_{\text{N}}r_{\text{U}}^2}{M_{\text{S}}(r_{\text{N}}-r_{\text{U}})^2} \quad (1)$$

Applying Kepler's third law to Uranus yields:

$$T_{\text{U}}^2=Cr_{\text{U}}^3 \quad (2)$$

Applying Kepler's third law to Neptune yields:

$$T_{\text{N}}^2=Cr_{\text{N}}^3 \quad (3)$$

Divide equation (3) by equation (2) to obtain:

$$\frac{T_{\text{N}}^2}{T_{\text{U}}^2}=\frac{Cr_{\text{N}}^3}{Cr_{\text{U}}^3}=\frac{r_{\text{N}}^3}{r_{\text{U}}^3}\Rightarrow r_{\text{N}}=r_{\text{U}}\left(\frac{T_{\text{N}}}{T_{\text{U}}}\right)^{2/3}$$

Substitute for r_{N} in equation (1) to obtain:

$$\frac{F_{\text{g,N-U}}}{F_{\text{g,U-S}}}=\frac{M_{\text{N}}r_{\text{U}}^2}{M_{\text{S}}\left(r_{\text{U}}\left(\frac{T_{\text{N}}}{T_{\text{U}}}\right)^{2/3}-r_{\text{U}}\right)^2}$$

Simplifying this expression yields:

$$\frac{F_{\text{g,N-U}}}{F_{\text{g,U-S}}}=\frac{M_{\text{N}}}{M_{\text{S}}\left(\left(\frac{T_{\text{N}}}{T_{\text{U}}}\right)^{2/3}-1\right)^2}$$

Because $M_N = 17.1M_E$ and $M_S = 333{,}000M_E$:

$$\frac{F_{g,N\text{-}U}}{F_{g,U\text{-}S}} = \frac{17.1M_E}{3.33\times10^5 M_E\left(\left(\dfrac{T_N}{T_U}\right)^{2/3}-1\right)^2} = \frac{17.1}{3.33\times10^5\left(\left(\dfrac{T_N}{T_U}\right)^{2/3}-1\right)^2}$$

Substitute numerical values and evaluate $\dfrac{F_{g,N\text{-}U}}{F_{g,U\text{-}S}}$:

$$\frac{F_{g,N\text{-}U}}{F_{g,U\text{-}S}} = \frac{17.1}{3.33\times10^5\left(\left(\dfrac{164.8\text{ y}}{84.0\text{ y}}\right)^{2/3}-1\right)^2} \approx 2\times10^{-4}$$

Because this ratio is so small, during the time at which Neptune is closest to Uranus, the force exerted on Uranus by Neptune is much less than the force exerted on Uranus by the Sun.

96 •• It is believed that there is a ″super-massive″ black hole at the center of our galaxy. One datum that leads to this conclusion is the important recent observation of stellar motion in the vicinity of the galactic center. If one such star moves in an elliptical orbit with a period of 15.2 years and has a semi-major axis of 5.5 light-days (the distance light travels in 5.5 days), what is the mass around which the star moves in its Keplerian orbit?

Picture the Problem We can apply Kepler’s third law to the orbital motion of the star to find the effective mass around which it is moving.

Using Kepler’s third law, relate the orbital period of the star to the semi-major axis of its orbit:

$$T^2 = \frac{4\pi^2}{GM}a^3 \Rightarrow M = \frac{4\pi^2 a^3}{GT^2}$$

where M is the mass around which the star moves in its Keplerian orbit.

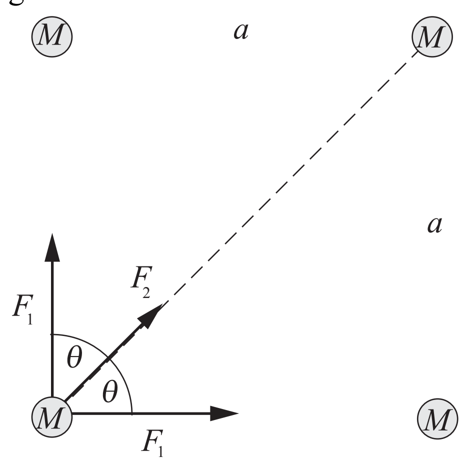
Substitute numerical values and evaluate M:

$$M = \frac{4\pi^2\left(5.5\ \text{d}\times\frac{86400\ \text{s}}{\text{d}}\times 2.998\times10^8\ \text{m/s}\right)^3}{\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(15.2\ \text{y}\times\frac{3.156\times10^7\ \text{s}}{\text{y}}\right)^2} = 7.434\times10^{36}\ \text{kg}$$

$$= 7.434\times10^{36}\ \text{kg}\times\frac{1\,M_{\text{Sun}}}{1.99\times10^{30}\ \text{kg}} = \boxed{3.7\times10^6\ M_{\text{Sun}}}$$

97 •• [SSM] Four identical planets are arranged in a square as shown in Figure 11-29. If the mass of each planet is M and the edge length of the square is a, what must be their speed if they are to orbit their common center under the influence of their mutual attraction?

Picture the Problem Note that, due to the symmetrical arrangement of the planets, each experiences the same centripetal force. We can apply Newton's second law to any of the four planets to relate its orbital speed to this net (centripetal) force acting on it.



Applying $\sum \vec{F}_{\text{radial}} = m\vec{a}_{\text{radial}}$ to one of the planets gives:

$$F_c = 2F_1\cos\theta + F_2$$

Substituting for F_1, F_2, and θ and simplifying yields:

$$F_c = \frac{2GM^2}{a^2}\cos 45° + \frac{GM^2}{\left(\sqrt{2}a\right)^2} = \frac{2GM^2}{a^2}\frac{1}{\sqrt{2}} + \frac{GM^2}{2a^2} = \frac{GM^2}{a^2}\left(\sqrt{2}+\frac{1}{2}\right)$$

Because $F_c = \dfrac{Mv^2}{a/\sqrt{2}} = \dfrac{\sqrt{2}Mv^2}{a}$

$$\frac{\sqrt{2}Mv^2}{a} = \frac{GM^2}{a^2}\left(\sqrt{2}+\frac{1}{2}\right)$$

Solve for v to obtain:

$$v = \sqrt{\frac{GM}{a}\left(1+\frac{1}{2\sqrt{2}}\right)} = \boxed{1.16\sqrt{\frac{GM}{a}}}$$

98 •• A hole is drilled from the surface of Earth to its center as in Figure 11-30. Ignore Earth's rotation and any effects due to air resistance, and model Earth as a uniform sphere. (*a*) How much work is required to lift a particle of mass *m* from the center of Earth to Earth's surface? (*b*) If the particle is dropped from rest at the surface of Earth, what is its speed when it reaches the center of Earth? (*c*) What is the escape speed for a particle projected from the center of Earth? Express your answers in terms of *m, g,* and R_E.

Picture the Problem Let *r* represent the separation of the particle from the center of Earth and assume a uniform density for Earth. The work required to lift the particle from the center of Earth to its surface is the line integral of the gravitational force function. This function can be found from the law of gravity and by relating the mass of Earth between the particle and the center of Earth to Earth's mass. We can use the work-kinetic energy theorem to find the speed with which the particle, when released from the surface of Earth, will strike the center of Earth. Finally, the energy required for the particle to escape Earth from the center of Earth is the sum of the energy required to get it to the surface of Earth and the kinetic energy it must have to escape from the surface of Earth.

(*a*) Express the work required to lift the particle from the center of Earth to Earth's surface:

$$W = \int_0^R \vec{F}\cdot d\vec{r} = -\int_0^R \vec{F}_g \cdot d\vec{r} = \int_0^{R_E} F_g dr \quad (1)$$

where F_g is the gravitational force acting on the particle.

Using the law of gravity, express the force acting on the particle as a function of its distance from the center of Earth:

$$F_g = \frac{GmM}{r^2} \quad (2)$$

where M is the mass of a sphere whose radius is r.

Express the ratio of M to M_E and simplify to obtain:

$$\frac{M}{M_E} = \frac{\rho\left(\frac{4}{3}\pi r^3\right)}{\rho\left(\frac{4}{3}\pi R_E^3\right)} = \frac{r^3}{R_E^3} \Rightarrow M = M_E\frac{r^3}{R_E^3}$$

Substitute for M in equation (2) to obtain:

$$F_g = \frac{GmM_E}{R_E^3}r = \frac{mgR_E^2}{R_E^3}r = \frac{mg}{R_E}r$$

Substitute for F_g in equation (1) and evaluate the integral:

$$W = \frac{mg}{R_E}\int_0^{R_E} r\,dr = \boxed{\tfrac{1}{2}gmR_E}$$

(*b*) Use the work-kinetic energy theorem to relate the kinetic energy of the particle as it reaches the center of Earth to the work done on it in moving it to the surface of Earth:

$$W = \Delta K = \tfrac{1}{2}mv^2$$

Substituting for W yields:

$$\tfrac{1}{2}gmR_E = \tfrac{1}{2}mv^2 \Rightarrow v = \boxed{\sqrt{gR_E}}$$

(*c*) Express the total energy required for the particle to escape when projected from the center of Earth:

$$E_{esc} = W + \tfrac{1}{2}mv_e^2 = \tfrac{1}{2}mv_{esc}^2$$

where v_e is the escape speed from the surface of Earth.

Substituting for W yields:

$$\tfrac{1}{2}gmR_E + \tfrac{1}{2}mv_e^2 = \tfrac{1}{2}mv_{esc}^2$$

or, simplifying,

$$gR_E + v_e^2 = v_{esc}^2$$

Because $v_e^2 = \dfrac{2GM}{R_E}$:

$$gR_E + \frac{2GM}{R_E} = v_{esc}^2 \qquad (3)$$

Apply Newton's second law to an object of mass m at the surface of Earth to obtain:

$$mg = \frac{GMm}{R_E^2} \Rightarrow \frac{GM}{R_E} = gR_E$$

Substitute for GM/R_E in equation (3) to obtain:

$$gR_E + 2gR_E = v_{esc}^2 \Rightarrow v_{esc} = \boxed{\sqrt{3gR_E}}$$

Remarks: This escape speed is approximately 122% of the escape speed from the surface of Earth.

99 •• A thick spherical shell of mass M and uniform density has an inner radius R_1 and an outer radius R_2. Find the gravitational field g_r as a function of r for $0 < r < \infty$. Sketch a graph of g_r versus r.

Picture the Problem We need to find the gravitational field in three regions: $r < R_1$, $R_1 < r < R_2$, and $r > R_2$.

For $r < R_1$: $$g(r < R_1) = \boxed{0}$$

For $r > R_2$, $g(r)$ is the field due to the thick spherical shell of mass M centered at the origin: $$g(r > R_2) = \boxed{\frac{GM}{r^2}}$$

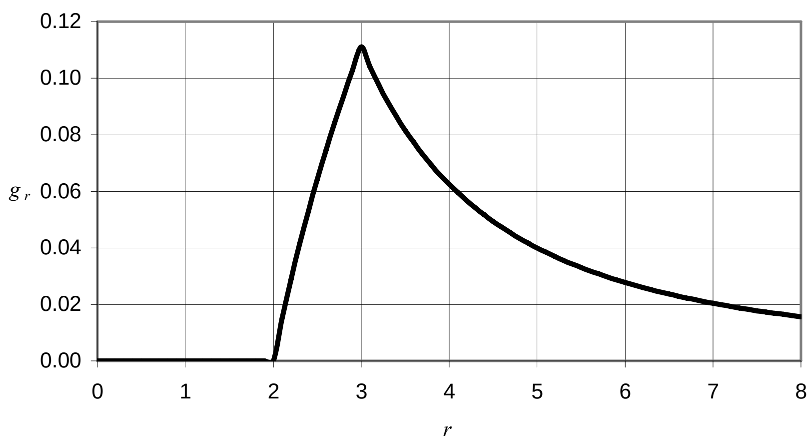
For $R_1 < r < R_2$, $g(r)$ is determined by the mass within the shell of radius r: $$g(R_1 < r < R_2) = \frac{Gm}{r^2} \qquad (1)$$
where $m = \frac{4}{3}\pi\rho\left(r^3 - R_1^3\right) \qquad (2)$

Express the density of the spherical shell: $$\rho = \frac{M}{V} = \frac{M}{\frac{4}{3}\pi\left(R_2^3 - R_1^3\right)}$$

Substitute for ρ in equation (2) and simplify to obtain: $$m = \frac{M\left(r^3 - R_1^3\right)}{R_2^3 - R_1^3}$$

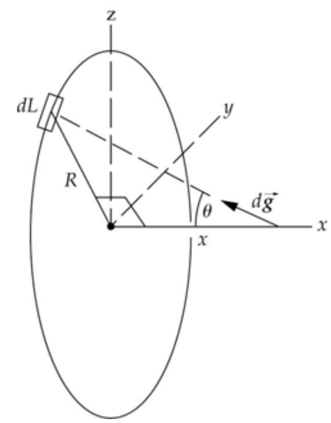
Substitute for m in equation (1) to obtain: $$g_r = \boxed{\frac{GM\left(r^3 - R_1^3\right)}{r^2\left(R_2^3 - R_1^3\right)}}$$

A graph of g_r with $R_1 = 2$, $R_2 = 3$, and $GM = 1$ follows:



100 •• (*a*) A thin uniform ring of mass M and radius R lies in the $x = 0$ plane and is centered at the origin. Sketch a plot of the gravitational field g_x versus x for all points on the x axis. (*b*) At what point, or points, on the axis is the magnitude of g_x a maximum?

Picture the Problem A ring of radius R is shown to the right. Choose a coordinate system in which the origin is at the center of the ring and x axis is as shown. An element of length dL and mass dm is responsible for the field dg at a distance x from the center of the ring. We can express the x component of dg and then integrate over the circumference of the ring to find the total field as a function of x.



(a) Express the differential gravitational field at a distance x from the center of the ring in terms of the mass of an elemental segment of length dL:

$$dg = \frac{Gdm}{R^2 + x^2}$$

Relate the mass of the element to its length:

$$dm = \lambda\, dL$$

where λ is the linear density of the ring.

Substitute for dm to obtain:

$$dg = \frac{G\lambda\, dL}{R^2 + x^2}$$

By symmetry, the y and z components of g vanish. The x component of dg is:

$$dg_x = dg\cos\theta = \frac{G\lambda\, dL}{R^2 + x^2}\cos\theta$$

Refer to the figure to obtain:

$$\cos\theta = \frac{x}{\sqrt{R^2 + x^2}}$$

Substituting for $\cos\theta$ yields:

$$dg_x = \frac{G\lambda\, dL}{R^2 + x^2}\frac{x}{\sqrt{R^2 + x^2}} = \frac{G\lambda\, xdL}{\left(R^2 + x^2\right)^{3/2}}$$

Because $\lambda = \dfrac{M}{2\pi R}$:

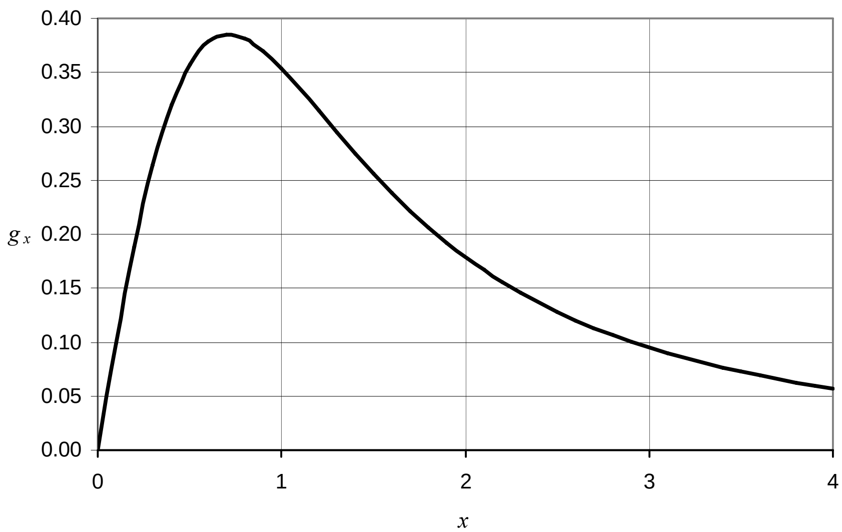
$$dg_x = \frac{GM\, xdL}{2\pi R\left(R^2 + x^2\right)^{3/2}}$$

Integrate to find g_x:

$$g_x = \frac{GM\,x}{2\pi R\left(R^2 + x^2\right)^{3/2}} \int_0^{2\pi R} dL$$

$$= \boxed{\frac{GM}{\left(R^2 + x^2\right)^{3/2}}\,x}$$

A graph of g_x follows. The curve is normalized with $R = 1$ and $GM = 1$.



(b) Differentiate $g(x)$ with respect to x and set the derivative equal to zero to identify extreme values:

$$\frac{dg}{dx} = GM\left[\frac{\left(x^2 + R^2\right)^{3/2} - x\left(\frac{3}{2}\right)\left(x^2 + R^2\right)^{1/2}(2x)}{\left(R^2 + x^2\right)^3}\right] = 0 \text{ for extrema}$$

Simplify to obtain:

$$\left(x^2 + R^2\right)^{3/2} - 3x^2\left(x^2 + R^2\right)^{1/2} = 0$$

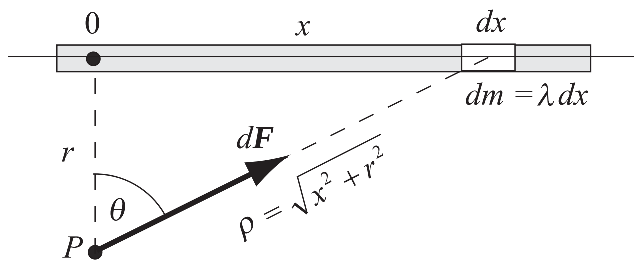
Solving for x yields:

$$x = \boxed{\pm\frac{R}{\sqrt{2}}}$$

Because the curve is concave downward, we can conclude that this result corresponds to a maximum. Note that this result agrees with our graphical maximum.

101 ••• Find the magnitude of the gravitational field a distance r from an infinitely long uniform thin rod whose mass per unit length is λ.

Picture the Problem The diagram shows a segment of the wire of length dx and mass $dm = \lambda dx$ at a distance x from the origin of our coordinate system. We can find the magnitude of the gravitational field at a distance r from the wire from the resultant gravitational force acting on a particle of mass m located at point P and then integrating over the length of the wire.



The magnitude of the gravitational field at P is given by:

$$g = \frac{F}{m}$$

Express the gravitational force acting on a particle of mass m at a distance r from the wire due to the segment of the wire of length dx:

$$F = 2\int_0^{90^\circ} \frac{Gm\,dm\cos\theta}{\rho^2}$$

Substituting for F and dm gives:

$$g = 2\int_0^{90^\circ} \frac{G\lambda dx\cos\theta}{\rho^2}$$

Because $\tan\theta = \frac{x}{r}$:

$$dx = r\sec^2\theta d\theta = \frac{r d\theta}{\cos^2\theta}$$

Note that $\rho = r/\cos\theta$ and substitute for dx and ρ in the expression for x and simplify to obtain:

$$g = 2\int_0^{90^\circ} \frac{G\lambda r d\theta\cos\theta}{\cos^2\theta\left(\frac{r^2}{\cos^2\theta}\right)}$$

$$= \frac{2G\lambda}{r}\int_0^{90^\circ}\cos\theta d\theta = \boxed{\frac{2G\lambda}{r}}$$

102 ••• One question in early planetary science was whether each of the rings of Saturn were solid or were, instead, composed of individual chunks, each in its own orbit. The issue could be resolved by an observation in which astronomers would measure the speed of the inner and outer portions of the ring. If the inner portion of the ring moved more slowly than the outer portion, then the ring was solid; if the opposite was true, then it was actually composed of separate chunks. Let us see how this results from a theoretical viewpoint. Let the radial

width of a given ring (there are many) be Δr, the average distance of that ring from the center of Saturn be represented by R, and the average speed of that ring be v_{avg}. (*a*) If the ring is solid, show that the *difference* in speed between its outermost and innermost portions, Δv, is given by the approximate expression $\Delta v = v_{\text{out}} - v_{\text{in}} \approx v_{\text{avg}} \dfrac{\Delta r}{R}$. Here, v_{out} is the speed of the outermost portion of the ring, and v_{in} is the speed of the innermost portion. (*b*) If, however, the ring is composed of many small chunks, show that $\Delta v \approx -\frac{1}{2}\left(v_{\text{avg}}\,\Delta r/R\right)$. (Assume that $\Delta r << R$.)

Picture the Problem We can use the relationship between the angular speed of an orbiting object and its tangential velocity to express the speeds v_{in} and v_{out} of the innermost and outermost portions of the ring. In Part (*b*) we can use Newton's law of gravity, in conjunction with Newton's second law, to relate the tangential speed of a chunk of the ring to the gravitational force acting on it. As in Part (*a*), once we know v_{in} and v_{out}, we can express the difference between them to obtain the desired results.

(*a*) The difference between v_{out} and v_{in} is:

$$\Delta v = v_{\text{out}} - v_{\text{in}} \qquad (1)$$

The speed of a point in the ring at the average distance R from the center of Saturn under the assumption that the ring is solid and rotates with an angular speed ω is given by:

$$v(R) = \omega R$$

Express the speeds v_{in} and v_{out} of the innermost and outermost portions of the ring:

$$v_{\text{in}} = \left(R - \tfrac{1}{2}\Delta r\right)\omega$$
and
$$v_{\text{out}} = \left(R + \tfrac{1}{2}\Delta r\right)\omega$$

Substituting for v_{in} and v_{out} in equation (1) and simplifying yields:

$$\Delta v = \left(R + \tfrac{1}{2}\Delta r\right)\omega - \left(R - \tfrac{1}{2}\Delta r\right)\omega$$
$$= \omega\Delta r = \frac{v_{\text{avg}}}{R}\Delta r = \boxed{v_{\text{avg}}\frac{\Delta r}{R}}$$

(*b*) Assume that a chunk of the ring is moving in a circular orbit around the center of Saturn under the force of gravity and apply Newton's second law to obtain:

$$\sum F_{\text{radial}} = \frac{GMm}{R'^2} = m\frac{v^2}{R'} \Rightarrow v = \sqrt{\frac{GM}{R'}}$$
where M is the mass of Saturn and R' the distance from its center.

Express v_{out} by substituting for $R+\frac{1}{2}\Delta r$ for R' and simplifying:

$$v_{out}=\sqrt{\frac{GM}{R+\frac{1}{2}\Delta r}}=\sqrt{\frac{GM}{R\left(1+\frac{1}{2}\frac{\Delta r}{R}\right)}}$$

$$=\sqrt{\frac{GM}{R}}\left(1+\frac{1}{2}\frac{\Delta r}{R}\right)^{-1/2}$$

Expanding $\left(1+\frac{1}{2}\frac{\Delta r}{R}\right)^{-1/2}$ binomially, discarding higher-order terms, and simplifying yields:

$$v_{out}=\sqrt{\frac{GM}{R}}\left(1-\frac{1}{2}\left(\frac{1}{2}\frac{\Delta r}{R}\right)\right.$$
$$\left.+\text{higher order terms}\right)$$

$$\approx\sqrt{\frac{GM}{R}}\left(1-\frac{1}{4}\frac{\Delta r}{R}\right)$$

Proceed similarly to obtain, for v_{in}:

$$v_{in}\approx\sqrt{\frac{GM}{R}}\left(1+\frac{1}{4}\frac{\Delta r}{R}\right)$$

Express the difference between v_{out} and v_{in} and simplify to obtain:

$$\Delta v=v_{out}-v_{in}\approx\sqrt{\frac{GM}{R}}\left(1-\frac{1}{4}\frac{\Delta r}{R}\right)-\sqrt{\frac{GM}{R}}\left(1+\frac{1}{4}\frac{\Delta r}{R}\right)=\sqrt{\frac{GM}{R}}\left(-\frac{1}{2}\frac{\Delta r}{R}\right)$$

Because $v_{avg}=\sqrt{\frac{GM}{R}}$:

$$\Delta v\approx\boxed{-\frac{1}{2}\left(v_{avg}\frac{\Delta r}{R}\right)}$$

103 ••• [SSM] In this problem you are to find the gravitational potential energy of the thin rod in Example 11-8 and a point particle of mass m_0 that is on the x axis at $x = x_0$. (*a*) Show that the potential energy shared by an element of the rod of mass dm (shown in Figure 11-14) and the point particle of mass m_0 located at $x_0\geq\frac{1}{2}L$ is given by

$$dU=-\frac{Gm_0dm}{x_0-x_s}=-\frac{GMm_0}{L(x_0-x_s)}dx_s$$

where $U = 0$ at $x_0 = \infty$. (*b*) Integrate your result for Part (*a*) over the length of the rod to find the total potential energy for the system. Generalize your function $U(x_0)$ to any place on the x axis in the region $x > L/2$ by replacing x_0 by a general coordinate x and write it as $U(x)$. (*c*) Compute the force on m_0 at a general point x using $F_x = –dU/dx$ and compare your result with m_0g, where g is the field at x_0 calculated in Example 11-8.

Picture the Problem Let $U = 0$ at $x = \infty$. The potential energy of an element of the stick dm and the point mass m_0 is given by the definition of gravitational potential energy: $dU=-Gm_0dm/r$ where r is the separation of dm and m_0.

(*a*) Express the potential energy of the masses m_0 and dm:

$$dU = -\frac{Gm_0 dm}{x_0 - x_s}$$

The mass dm is proportional to the size of the element dx_s:

$$dm = \lambda\, dx_s$$

where $\lambda = \frac{M}{L}$.

Substitute for dm and λ to express dU in terms of x_s:

$$dU = -\frac{Gm_0 \lambda\, dx_s}{x_0 - x_s} = \boxed{-\frac{GMm_0\, dx_s}{L(x_0 - x_s)}}$$

(*b*) Integrate dU to find the total potential energy of the system:

$$U = -\frac{GMm_0}{L}\int_{-L/2}^{L/2}\frac{dx_s}{x_0 - x_s} = \frac{GMm_0}{L}\left[\ln\left(x_0 - \frac{L}{2}\right) - \ln\left(x_0 + \frac{L}{2}\right)\right]$$

$$= \boxed{-\frac{GMm_0}{L}\ln\left(\frac{x_0 + L/2}{x_0 - L/2}\right)}$$

(*c*) Because x_0 is a general point along the x axis:

$$F(x_0) = -\frac{dU}{dx_0} = \frac{GMm_0}{L}\left[\frac{1}{x_0 + \frac{L}{2}} - \frac{1}{x_0 - \frac{L}{2}}\right]$$

Further simplification yields:

$$F(x_0) = -\frac{Gmm_0}{x^2 - L^2/4}$$

This answer and the answer given in Example 11-8 are the same.

104 ••• A uniform sphere of mass M is located near a thin, uniform rod of mass m and length L as in Figure 11-31. Find the gravitational force of attraction exerted by the sphere on the rod.

Picture the Problem Choose a mass element dm of the rod of thickness dx at a distance x from the origin. All such elements of the rod experience a gravitational force dF due to presence of the sphere centered at the origin. We can find the total gravitational force of attraction experienced by the rod by integrating dF from $x = a$ to $x = a + L$.

Express the gravitational force dF acting on the element of the rod of mass dm:

$$dF = \frac{GMdm}{x^2}$$

Express dm in terms of the mass m and length L of the rod:

$$dm = \frac{m}{L}dx$$

Substitute for dm to obtain:

$$dF = \frac{GMm}{L}\frac{dx}{x^2}$$

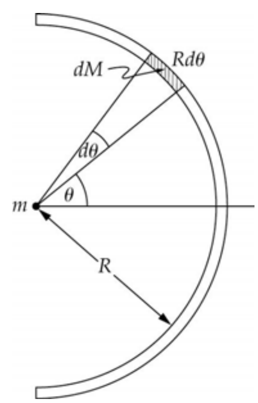
Integrate dF from $x = a$ to $x = a + L$ to find the total gravitational force acting on the rod:

$$F = \frac{GMm}{L}\int_a^{a+L} x^{-2}dx = -\frac{GMm}{L}\left[\frac{1}{x}\right]_a^{a+L}$$

$$= \boxed{\frac{GMm}{a(a+L)}}$$

105 ••• A thin uniform 20-kg rod with a length equal to 5.0 m is bent into a semicircle. What is the gravitational force exerted by the rod on a 0.10-kg point mass located at the center of curvature of the circular arc?

Picture the Problem The semicircular rod is shown in the figure. We'll use an element of length $Rd\theta = (L/\pi)d\theta$ whose mass dM is $(M/\pi)d\theta$. By symmetry, $F_y = 0$. We'll first find dF_x and then integrate over θ from $-\pi/2$ to $\pi/2$.



Express dF_x:

$$dF_x = \frac{GmdM}{R^2} = \frac{GMm}{\pi\left(\frac{L}{\pi}\right)^2}d\theta\cos\theta$$

Integrate dF_x over θ from $-\pi/2$ to $\pi/2$:

$$F_x = \frac{\pi\, GMm}{L^2}\int_{-\pi/2}^{\pi/2}\cos\theta\, d\theta = \frac{2\pi\, GMm}{L^2}$$

Substitute numerical values and evaluate F_x:

$$F_x = \frac{2\pi\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)(20\,\text{kg})(0.10\,\text{kg})}{(5.0\,\text{m})^2} = \boxed{34\,\text{pN}}$$

106 ••• Both the Sun and the moon exert gravitational forces on the oceans of Earth, causing tides. (*a*) Show that the ratio of the force exerted on a point particle on the surface of Earth by the Sun to that exerted by the moon is $M_s r_m^2 / M_m r_s^2$. Here M_s and M_m represent the masses of the Sun and moon and r_s and r_m are the distances of the particle from Earth to the Sun and Earth to the moon, respectively. Evaluate this ratio numerically. (*b*) Even though the Sun exerts a much greater force on the oceans than does the moon, the moon has a greater effect on the tides because it is the *difference* in the force from one side of Earth to the other that is important. Differentiate the expression $F = G\, m_1 m_2/r^2$ to calculate the change in F due to a small change in r. Show that $dF/F = (-2\ dr)/r$. (*c*) The oceanic *tidal bulge* (that is, the elongation of the liquid water of the oceans causing two opposite high and two opposite low spots) is caused by the difference in gravitational force on the oceans from one side of Earth to the other. Show that for a small difference in distance compared to the average distance, the ratio of the differential gravitational force exerted by the Sun to the differential gravitational force exerted by the moon on Earth's oceans is given by $\Delta F_s / \Delta F_m \approx \left(M_s r_m^3\right) / \left(M_m r_s^3\right)$. Calculate this ratio. What is your conclusion? Which object, the moon or the Sun, is the main cause of the tidal stretching of the oceans on Earth?

Picture the Problem We can begin by expressing the forces exerted by the Sun and the moon on a body of water of mass *m* and taking the ratio of these forces. In (*b*) we'll simply follow the given directions and in (*c*) we can approximate differential quantities with finite quantities to establish the given ratio.

(*a*) Express the force exerted by the sun on a body of water of mass *m*:

$$F_S = \frac{GM_S m}{r_S^2}$$

Express the force exerted by the moon on a body of water of mass *m*:

$$F_m = \frac{GM_m m}{r_m^2}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{F_S}{F_m} = \boxed{\frac{M_S r_m^2}{M_m r_S^2}}$$

Substitute numerical values and evaluate this ratio:

$$\frac{F_S}{F_m} = \frac{\left(1.99\times10^{30}\ \text{kg}\right)\left(3.84\times10^{8}\ \text{m}\right)^2}{\left(7.36\times10^{22}\ \text{kg}\right)\left(1.50\times10^{11}\ \text{m}\right)^2} = \boxed{177}$$

(*b*) Find $\dfrac{dF}{dr}$:

$$\frac{dF}{dr} = -\frac{2Gm_1 m_2}{r^3} = -2\frac{F}{r}$$

Solve for the ratio $\frac{dF}{F}$:

$$\frac{dF}{F} = \boxed{-2\frac{dr}{r}}$$

(*c*) Express the change in force ΔF for a small change in distance Δr:

$$\Delta F = -2\frac{F}{r}\Delta r$$

Express ΔF_S:

$$\Delta F_S = -2\frac{\frac{GmM_S}{r_S^2}}{r_S}\Delta r_S = -2\frac{GmM_S}{r_S^3}\Delta r_S$$

Express ΔF_m:

$$\Delta F_m = -2\frac{GmM_m}{r_m^3}\Delta r_m$$

Divide the first of these equations by the second and simplify:

$$\frac{\Delta F_S}{\Delta F_m} = \frac{\frac{M_S}{r_S^3}\Delta r_S}{\frac{M_m}{r_m^3}\Delta r_m} = \frac{M_S r_m^3}{M_m r_S^3}\frac{\Delta r_S}{\Delta r_m}$$

Because $\frac{\Delta r_S}{\Delta r_m} = 1$:

$$\frac{\Delta F_S}{\Delta F_m} = \boxed{\frac{M_S r_m^3}{M_m r_S^3}}$$

Substitute numerical values and evaluate this ratio:

$$\frac{\Delta F_S}{\Delta F_m} = \frac{(1.99\times10^{30}\text{ kg})(3.84\times10^{8}\text{ m})^3}{(7.36\times10^{22}\text{ kg})(1.50\times10^{11}\text{ m})^3} = \boxed{0.454}$$

Because the ratio of the forces is less than one, the moon is the main cause of the tidal stretching of the oceans on Earth.

107 ••• United Federation Starship *Excelsior* is dropping two small robotic probes towards the surface of a neutron star for exploration. The mass of the star is the same as that of the Sun, but the star's diameter is only 10 km. The robotic probes are linked together by a 1.0-m-long steel cord (which includes communication lines between the two probes), and are dropped vertically (that is, one always above the other). The ship hovers at rest above the star's surface. As the Chief of Materials Engineering on the ship, you are concerned that the communication between the two probes, a crucial aspect of the mission, will not survive. (*a*) Outline your briefing session to the mission commander and explain the existence of a "stretching force" that will try to pull the robots apart as they fall toward the planet. (See Problem 106 for hints.) (*b*) Assume that the cord in use has a breaking tension of 25 kN and that the robots each have a mass of

1.0 kg. How close will the robots be to the surface of the star before the cord breaks?

Picture the Problem Let M_{NS} be the mass of the neutron star and m the mass of each robot. We can use Newton's law of gravity to express the difference in the tidal-like forces acting on the coupled robots. Expanding the expression for the force on the robot further from the neutron star binomially will lead us to an expression for the distance at which the breaking tension in the connecting cord will be exceeded.

(*a*) The gravitational force is greater on the lower robot, so if it were not for the cable its acceleration would be greater than that of the upper robot and they would separate. In opposing this separation the cable is stressed.

(*b*) Letting the separation of the two robots be Δr, and the distance from the center of the star to the lower robot be r, use Newton's law of gravity to express the difference in the forces acting on the robots:

$$F_{\text{tide}} = \frac{GM_{NS}m}{r^2} - \frac{GM_{NS}m}{(r+\Delta r)^2}$$

$$= GM_{NS}m\left[\frac{1}{r^2} - \frac{1}{r^2\left(1+\frac{\Delta r}{r}\right)^2}\right]$$

$$= \frac{GM_{NS}m}{r^2}\left[1-\left(1+\frac{\Delta r}{r}\right)^{-2}\right]$$

Expand the expression in the square brackets binomially and simplify to obtain:

$$1-\left(1+\frac{\Delta r}{r}\right)^{-2} \approx 1-\left(1-2\frac{\Delta r}{r}\right)$$

$$= 2\frac{\Delta r}{r}$$

Substituting yields:

$$F_{\text{tide}} \approx \frac{2GM_{NS}m}{r^3}\Delta r$$

Letting F_B be the breaking tension of the cord, substitute for F_{tide} and solve for the value of r corresponding to the breaking strain being exceeded:

$$r = \sqrt[3]{\frac{2GM_{NS}m}{F_B}\Delta r}$$

Substitute numerical values and evaluate r:

$$r = \sqrt[3]{\frac{2(6.673\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\,\text{kg})(1.0\,\text{kg})}{25\,\text{kN}}(1.0\,\text{m})} = \boxed{2.2\times10^5\ \text{m}}$$

Chapter 12
Static Equilibrium and Elasticity

Conceptual Problems

1 • **[SSM]** True or false:

(*a*) $\sum_i \vec{F}_i = 0$ is sufficient for static equilibrium to exist.
(*b*) $\sum_i \vec{F}_i = 0$ is necessary for static equilibrium to exist.
(*c*) In static equilibrium, the net torque about any point is zero.
(*d*) An object in equilibrium cannot be moving.

(*a*) False. The conditions $\sum \vec{F} = 0$ and $\sum \vec{\tau} = 0$ must be satisfied.

(*b*) True. The necessary and sufficient conditions for static equilibrium are $\sum \vec{F} = 0$ and $\sum \vec{\tau} = 0$.

(*c*) True. The conditions $\sum \vec{F} = 0$ and $\sum \vec{\tau} = 0$ must be satisfied.

(*d*) False. An object can be moving with constant speed (translational or rotational) when the conditions $\sum \vec{F} = 0$ and $\sum \vec{\tau} = 0$ are satisfied.

2 • True or false:

(*a*) The center of gravity is always at the geometric center of a body.
(*b*) The center of gravity must be located inside an object.
(*c*) The center of gravity of a baton is located between the two ends.
(*d*) The torque produced by the force of gravity about the center of gravity is always zero.

(*a*) False. The location of the center of gravity depends on how an object's mass is distributed.

(*b*) False. An example of an object for which the center of gravity is outside the object is a donut.

(*c*) True. The structure of a baton and the definition of the center of gravity guarantee that the center of gravity of a baton is located between the two ends.

(*d*) True. Because the force of gravity acting on an object acts through the center of gravity of the object, its lever (or moment) arm is always zero.

3 • The horizontal bar in Figure 12-27 will remain horizontal if (a) $L_1 = L_2$ and $R_1 = R_2$, (b) $M_1R_1 = M_2R_2$, (c) $M_2R_1 = R_2M_1$, (d) $L_1M_1 = L_2M_2$, (e) $R_1L_1 = R_2L_2$.

Determine the Concept The condition that the bar is in rotational equilibrium is that the net torque acting on it equal zero; i.e., $R_1M_1 - R_2M_2 = 0$. $\boxed{(b)}$ is correct.

4 • Sit in a chair with your back straight. Now try to stand up without leaning forward. Explain why you cannot do it.

Determine the Concept You cannot stand up because your body's center of gravity must be above your feet.

5 • You have a job digging holes for posts to support signs for a Louisiana restaurant (called Mosca's). Explain why the higher above the ground a sign is mounted, the farther the posts should extend into the ground.

Determine the Concept The higher the sign, the greater the torque about the horizontal axis through the lowest extremes of the posts for a given wind speed. In addition, the deeper the post holes the greater the maximum opposing torque about the same axis for a given consistency of the dirt. Thus, higher signs require deeper holes for the signposts.

6 • A father (mass M) and his son, (mass m) begin walking out towards opposite ends of a balanced see-saw. As they walk, the see-saw stays exactly horizontal. What can be said about the relationship between the father's speed V and the son's speed v?

Determine the Concept The question is about a situation in which an object is in static equilibrium. Both the father and son are walking outward from the center of the see-saw, which always remains in equilibrium. In order for this to happen, at any time, the net torque about any point (let's say, the pivot point at the center of the see-saw) must be zero. We can denote the father's position as X, and the son's position as x, and choose the origin of coordinates to be at the pivot point. At each moment, the see-saw exerts normal forces on the son and his father equal to their respective weights, mg and Mg. By Newton's third law, the father exerts a downward force equal in magnitude to the normal force, and the son exerts a downward force equal in magnitude to the normal force acting on him.

Apply $\sum\tau_{\text{pivot point}} = 0$ to the see-saw (assume that the father walks to the left and that counterclockwise torques are positive):

$$MgX - mgx = 0 \quad (1)$$

Express the distance both the father and his son walk as a function of time:

$X = V\Delta t$ and $x = v\Delta t$

Substitute for X and x in equation (1) to obtain:

$$MgV\Delta t - mgv\Delta t = 0 \Rightarrow V = \boxed{\frac{m}{M}v}$$

Remarks: The father's speed is less than the son's speed by a factor of *m*/*M*.

7 • Travel mugs that people might set on the dashboards of their cars are often made with broad bases and relatively narrow mouths. Why would travel mugs be designed with this shape, rather than have the roughly cylindrical shape that mugs normally have?

Determine the Concept The main reason this is done is to lower the center of gravity of the mug. The lower the center of gravity the more stable the mug is.

8 •• The sailors in the photo are using a technique called ″hiking out″. What purpose does positioning themselves in this way serve? If the wind were stronger, what would they need to do in order to keep their craft stable?

Determine the Concept Dynamically the boats are in equilibrium along their line of motion, but in the plane of their sail and the sailors, they are in static equilibrium. The torque on the boat, applied by the wind acting on the sail, has a tendency to tip the boat. The rudder counteracts that tendency to some degree, but in particularly strong winds, when the boat is sailing at particular angles with respect to the wind, the sailors need to ″hike out″ to apply some torque (due to the gravitational force of Earth on the sailors) by leaning outward on the beam of the boat. If the wind strengthens, they need to extend their bodies further over the side and may need to get into a contraption called a ″trapeze″ that enables the sailor to have his or her entire body outside the boat.

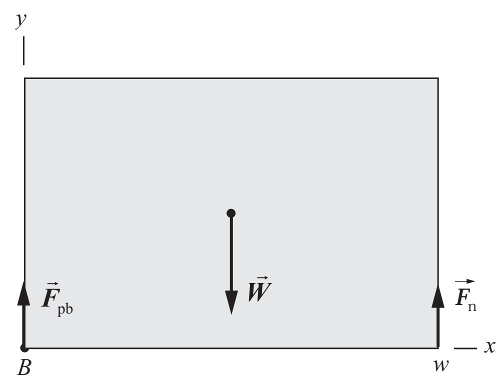
9 •• **[SSM]** An aluminum wire and a steel wire of the same length L and diameter D are joined end-to-end to form a wire of length $2L$. One end of the wire is then fastened to the ceiling and an object of mass M is attached to the other end. Neglecting the mass of the wires, which of the following statements is true? (*a*) The aluminum portion will stretch by the same amount as the steel portion. (*b*) The tensions in the aluminum portion and the steel portion are equal. (*c*) The tension in the aluminum portion is greater than that in the steel portion. (*d*) None of the above

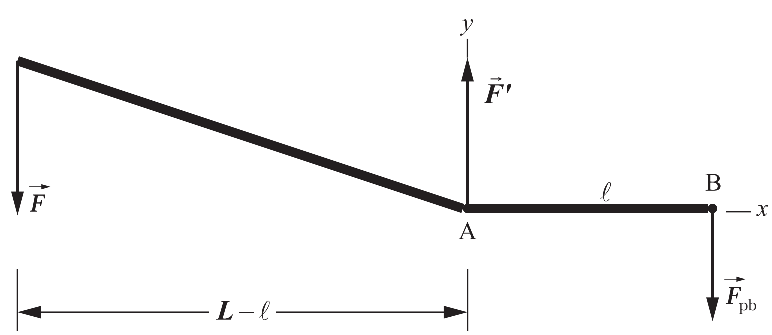
Determine the Concept We know that equal lengths of aluminum and steel wire of the same diameter will stretch different amounts when subjected to the same tension. Also, because we are neglecting the mass of the wires, the tension in them is independent of which one is closer to the roof and depends only on Mg. $\boxed{(b)}$ is correct.

Estimation and Approximation

10 •• A large crate weighing 4500 N rests on four 12-cm-high blocks on a horizontal surface (Figure 12-28). The crate is 2.0 m long, 1.2 m high and 1.2 m deep. You are asked to lift one end of the crate using a long steel pry bar. The fulcrum on the pry bar is 10 cm from the end that lifts the crate. Estimate the length of the bar you will need to lift the end of the crate.

Picture the Problem The diagram to the right shows the forces acting on the crate as it is being lifted at its left end. Note that when the crowbar lifts the crate, only half the weight of the crate is supported by the bar. Choose the coordinate system shown and let the subscript ″pb″ refer to the pry bar. The diagram below shows the forces acting on the pry bar as it is being used to lift the end of the crate.





Assume that the maximum force F you can apply is 500 N (about 110 lb). Let ℓ be the distance between the points of contact of the steel bar with the floor and the crate, and let L be the total length of the bar. Lacking information regarding the bend in pry bar at the fulcrum, we'll assume that it is small enough to be negligible. We can apply the condition for rotational equilibrium to the pry bar and a condition for translational equilibrium to the crate when its left end is on the verge of lifting.

Apply $\sum F_y = 0$ to the crate: $F_{\text{pb}} - W + F_{\text{n}} = 0$ (1)

Apply $\sum \vec{\tau} = 0$ to the crate about an axis through point B and perpendicular to the plane of the page to obtain: $wF_{\text{n}} - \frac{1}{2}wW = 0 \Rightarrow F_{\text{n}} = \frac{1}{2}W$ as noted in **Picture the Problem**.

Solve equation (1) for F_{pb} and substitute for F_{n} to obtain: $F_{\text{pb}} = W - \frac{1}{2}W = \frac{1}{2}W$

Apply $\sum \vec{\tau} = 0$ to the pry bar about an axis through point A and perpendicular to the plane of the page to obtain:

$$F(L-\ell) - \ell F_{\text{pb}} = 0 \Rightarrow L = \ell\left(1 + \frac{F_{\text{pb}}}{F}\right)$$

Substitute for F_{pb} to obtain:

$$L = \ell\left(1 + \frac{W}{2F}\right)$$

Substitute numerical values and evaluate L:

$$L = (0.10\,\text{m})\left(1 + \frac{4500\,\text{N}}{2(500\,\text{N})}\right) = \boxed{55\,\text{cm}}$$

11 •• **[SSM]** Consider an atomic model for Young's modulus. Assume that a large number of atoms are arranged in a cubic array, with each atom at a corner of a cube and each atom at a distance *a* from its six nearest neighbors. Imagine that each atom is attached to its 6 nearest neighbors by little springs each with force constant *k*. (*a*) Show that this material, if stretched, will have a Young's modulus $Y = k/a$. (*b*) Using Table 12-1 and assuming that $a \approx 1.0$ nm, estimate a typical value for the "atomic force constant" *k* in a metal.

Picture the Problem We can derive this expression by imagining that we pull on an area *A* of the given material, expressing the force each spring will experience, finding the fractional change in length of the springs, and substituting in the definition of Young's modulus.

(*a*) The definition of Young's modulus is:

$$Y = \frac{F/A}{\Delta L/L} \quad (1)$$

Express the elongation ΔL of each spring:

$$\Delta L = \frac{F_{\text{s}}}{k} \quad (2)$$

The force F_s each spring will experience as a result of a force F acting on the area A is:

$$F_s = \frac{F}{N}$$

Express the number of springs N in the area A:

$$N = \frac{A}{a^2}$$

Substituting for N yields:

$$F_s = \frac{Fa^2}{A}$$

Substitute F_s in equation (2) to obtain, for the extension of one spring:

$$\Delta L = \frac{Fa^2}{kA}$$

Assuming that the springs extend/compress linearly, the fractional extension of the springs is:

$$\frac{\Delta L_{\text{tot}}}{L} = \frac{\Delta L}{a} = \frac{1}{a}\frac{Fa^2}{kA} = \frac{Fa}{kA}$$

Substitute in equation (1) and simplify to obtain:

$$Y = \frac{\frac{F}{A}}{\frac{Fa}{kA}} = \boxed{\frac{k}{a}}$$

(*b*) From our result in Part (*a*):

$$k = Ya$$

From Table 12-1:

$$Y = 200\,\text{GN/m}^2 = 2.00\times10^{11}\ \text{N/m}^2$$

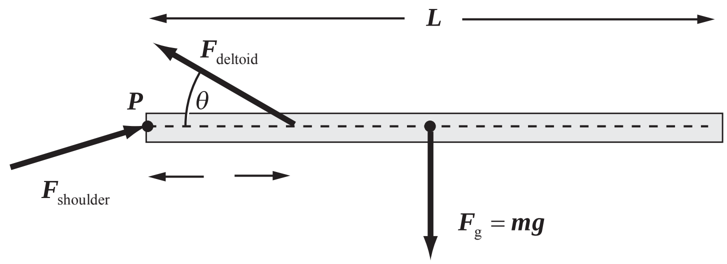
Substitute numerical values and evaluate k:

$$k = \left(2.00\times10^{11}\ \text{N/m}^2\right)\left(1.0\times10^{-9}\ \text{m}\right) = \boxed{2.0\,\text{N/cm}}$$

12 •• By considering the torques about the centers of the ball joints in your shoulders, estimate the force your deltoid muscles (those muscles on top of your shoulder) must exert on your upper arm, in order to keep your arm held out and extended at shoulder level. Then, estimate the force they must exert when you hold a 10-lb weight out to the side at arm's length.

Picture the Problem A model of your arm is shown in the pictorial representation. Your shoulder joint is at point P and the force the deltoid muscles exert on your extended arm $\vec{F}_{\text{deltoid}}$ is shown acting at an angle θ with the horizontal. The weight of your arm is the gravitational force $\vec{F}_g = m\vec{g}$ exerted by Earth through the center of gravity of your arm. We can use the condition for rotational equilibrium to estimate the forces exerted by your deltoid muscles. Note that, because its moment

arm is zero, the torque due to $\vec{F}_{\text{shoulder}}$ about an axis through point P and perpendicular to the page is zero.



Apply $\sum \tau_P = 0$ to your extended arm:

$$F_{\text{deltoid}}\ell\sin\theta - \tfrac{1}{2}mgL = 0 \qquad (1)$$

Solving for F_{deltoid} yields:

$$F_{\text{deltoid}} = \frac{mgL}{2\ell\sin\theta}$$

Assuming that $\ell \approx 20$ cm, $L \approx 60$ cm, $mg \approx 10$ lb, and $\theta \approx 10°$, substitute numerical values and evaluate F_{deltoid}:

$$F_{\text{deltoid}} = \frac{(10\text{ lb})(60\text{ cm})}{2(20\text{ cm})\sin 10°} \approx \boxed{86\text{ lb}}$$

If you hold a 10-lb weight at the end of your arm, equation (1) becomes:

$$F'_{\text{deltoid}}\ell\sin\theta - \tfrac{1}{2}mgL - m'gL = 0$$

where m' is the mass of the 10-lb weight.

Solving for F_{deltoid} yields:

$$F'_{\text{deltoid}} = \frac{mgL + 2m'gL}{2\ell\sin\theta}$$

Substitute numerical values and evaluate F'_{deltoid}:

$$F_{\text{deltoid}} = \frac{(10\text{ lb})(60\text{ cm}) + 2(10\text{ lb})(60\text{ cm})}{2(20\text{ cm})\sin 10°} \approx \boxed{260\text{ lb}}$$

Conditions for Equilibrium

13 • Your crutch is pressed against the sidewalk with a force $\vec{F}_{\text{c}}$ along its own direction, as shown in Figure 12-29. This force is balanced by the normal force $\vec{F}_{\text{n}}$ and a frictional force $\vec{f}_{\text{s}}$. (*a*) Show that when the force of friction is at its maximum value, the coefficient of friction is related to the angle θ by $\mu_{\text{s}} = \tan\theta$. (*b*) Explain how this result applies to the forces on your foot when you are not using a crutch. (*c*) Why is it advantageous to take short steps when walking on slippery surfaces?

Picture the Problem Choose a coordinate system in which upward is the $+y$ direction and to the right is the $+x$ direction and use the conditions for translational equilibrium.

(*a*) Apply $\sum \vec{F} = 0$ to the forces acting on the tip of the crutch:

$$\sum F_x = -f_s + F_c \sin\theta = 0 \qquad (1)$$

and

$$\sum F_y = F_n - F_c \cos\theta = 0 \qquad (2)$$

Solve equation (2) for F_n and assuming that $f_s = f_{s,max}$, obtain:

$$f_s = f_{s,max} = \mu_s F_n = \mu_s F_c \cos\theta$$

Substitute in equation (1) and solve for μ_s:

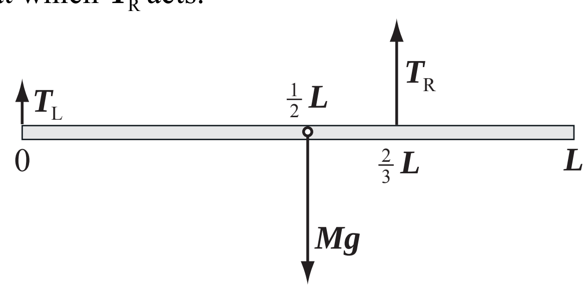
$$\mu_s = \boxed{\tan\theta}$$

(*b*) Taking long strides requires a large coefficient of static friction because θ is large for long strides.

(*c*) If μ_s is small, that is, there is ice on the surface, θ must be small to avoid slipping.

14 •• A thin uniform rod of mass M is suspended horizontally by two vertical wires. One wire is at the left end of the rod, and the other wire is 2/3 of the length of the rod from the left end. (*a*) Determine the tension in each wire. (*b*) An object is now hung by a string attached to the right end of the rod. When this happens, it is noticed that the rod remains horizontal but the tension in the wire on the left vanishes. Determine the mass of the object.

Picture the Problem The pictorial representation shows the thin rod with the forces described in Part (*a*) acting on it. We can apply $\sum \vec{\tau}_0 = 0$ to the rod to find the forces T_L and T_R. The simplest way to determine the mass m of the object suspended from the rod in (*b*) is to apply the condition for rotational equilibrium a second time, but this time with respect to an axis perpendicular to the page and through the point at which $\vec{T}_R$ acts.



(a) Apply $\sum \vec{\tau}_0 = 0$ to the rod: $\frac{2}{3}LT_R - \frac{1}{2}LMg = 0 \Rightarrow T_R = \boxed{\frac{3}{4}Mg}$

Apply $\sum \vec{F}_{\text{vertical}} = 0$ to the rod: $T_L - Mg + T_R = 0$

Substitute for T_R to obtain: $T_L - Mg + \frac{3}{4}Mg = 0 \Rightarrow T_L = \boxed{\frac{1}{4}Mg}$

(b) With an object of mass m suspended from the right end of the rod and $T_L = 0$, applying $\sum \vec{\tau} = 0$ about an axis perpendicular to the page and through the point at which $\vec{T}_R$ acts yields:

$$\left(\tfrac{2}{3} - \tfrac{1}{2}\right)LMg - \left(1 - \tfrac{2}{3}\right)Lmg = 0$$

Solving for m yields: $m = \boxed{\frac{1}{2}M}$

The Center of Gravity

15 • An automobile has 58 percent of its weight on the front wheels. The front and back wheels on each side are separated by 2.0 m. Where is the center of gravity located?

Picture the Problem Let the weight of the automobile be w. Choose a coordinate system in which the origin is at the point of contact of the front wheels with the ground and the positive x axis includes the point of contact of the rear wheels with the ground. Apply the definition of the center of gravity to find its location.

Use the definition of the center of gravity to obtain:

$$\begin{aligned} x_{cg}W &= \sum_i w_i x_i \\ &= 0.58w(0) + 0.42w(2.0\,\text{m}) \\ &= (0.84\,\text{m})w \end{aligned}$$

Because $W = w$: $x_{cg}w = (0.84\,\text{m})w \Rightarrow \boldsymbol{x}_{cg} = \boxed{84\,\text{cm}}$

Static Equilibrium

16 • Figure 12-30 shows a lever of negligible mass with a vertical force F_{app} being applied to lift a load F. The *mechanical advantage* of the lever is defined as $M = F/F_{\text{app, min}}$, where $F_{\text{app, min}}$ is the smallest force necessary to lift the load F. Show that for this simple lever system, $M = x/X$, where x is the moment arm (distance to the pivot) for the applied force and X is the moment arm for the load.

Picture the Problem We can use the given definition of the mechanical advantage of a lever and the condition for rotational equilibrium to show that $M = x/X$.

Express the definition of mechanical advantage for a lever:

$$M = \frac{F}{F_{\text{app, min}}} \tag{1}$$

Apply the condition for rotational equilibrium to the lever:

$$\sum \tau_{\text{fulcrum}} = xF_{\text{app, min}} - XF = 0$$

Solve for the ratio of F to $F_{\text{app, min}}$ to obtain:

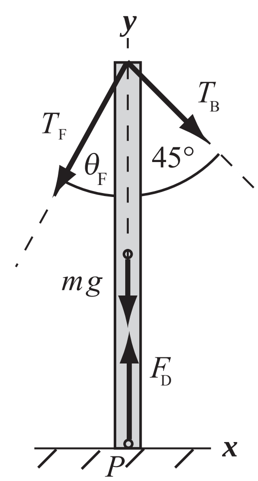
$$\frac{F}{F_{\text{app, min}}} = \frac{x}{X}$$

Substitute for $F/F_{\text{app, min}}$ in equation (1) to obtain:

$$M = \boxed{\frac{x}{X}}$$

17 • **[SSM]** Figure 12-31 shows a 25-foot sailboat. The mast is a uniform 120-kg pole that is supported on the deck and held fore and aft by wires as shown. The tension in the *forestay* (wire leading to the bow) is 1000 N. Determine the tension in the *backstay* (wire leading aft) and the normal force that the deck exerts on the mast. (Assume that the frictional force the deck exerts on the mast to be negligible.)

Picture the Problem The force diagram shows the forces acting on the mast. Let the origin of the coordinate system be at the foot of the mast with the $+x$ direction to the right and the $+y$ direction upward. Because the mast is in equilibrium, we can apply the conditions for translational and rotational equilibrium to find the tension in the backstay, T_B, and the normal force, F_D, that the deck exerts on the mast.



Apply $\sum \vec{\tau} = 0$ to the mast about an axis through point P:

$$(4.88\,\text{m})(1000\,\text{N})\sin\theta_F - (4.88\,\text{m})T_B \sin 45.0° = 0$$

Solve for T_B to obtain:

$$T_B = \frac{(1000\,\text{N})\sin\theta_F}{\sin 45.0°} \tag{1}$$

Find θ_F, the angle of the forestay with the vertical:

$$\theta_F = \tan^{-1}\left(\frac{2.74\,\text{m}}{4.88\,\text{m}}\right) = 29.3°$$

Substitute numerical values in equation (1) and evaluate T_B:

$$T_B = \frac{(1000\,\text{N})\sin 29.3°}{\sin 45.0°} = \boxed{692\,\text{N}}$$

Apply the condition for translational equilibrium in the y direction to the mast:

$$\sum F_y = F_D - T_F \cos\theta_F - T_B \cos 45° - mg = 0$$

Solving for F_D yields:

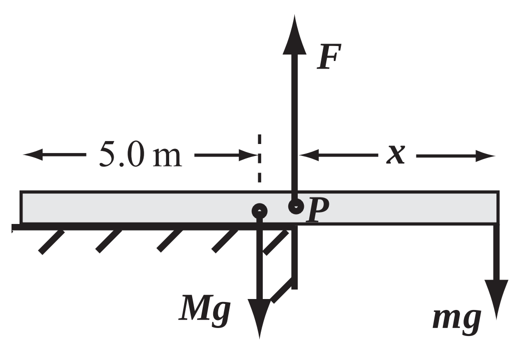
$$F_D = T_F \cos\theta_F + T_B \cos 45° + mg$$

Substitute numerical values and evaluate F_D:

$$F_D = (1000\text{ N})\cos 29.3° + (692\text{ N})\cos 45° + (120\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{2.54\,\text{kN}}$$

18 •• A uniform 10.0-m beam of mass 300 kg extends over a ledge as in Figure 12-32. The beam is not attached, but simply rests on the surface. A 60.0-kg student intends to position the beam so that he can walk to the end of it. What is the maximum distance the beam can extend past the end of the ledge and still allow him to perform this feat?

Picture the Problem The diagram shows $M\vec{g}$, the weight of the beam, $m\vec{g}$, the weight of the student, and the force the ledge exerts $\vec{F}$, acting on the beam. Because the beam is in equilibrium, we can apply the condition for rotational equilibrium to the beam to find the location of the pivot point P that will allow the student to walk to the end of the beam.



Apply $\sum \vec{\tau} = 0$ about an axis through the pivot point P:

$$Mg(5.0\,\text{m} - x) - mgx = 0$$

Solving for x yields:

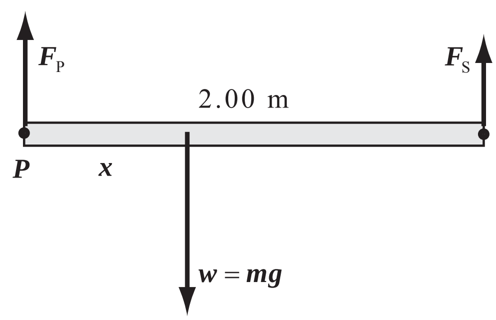
$$x = \frac{5.0M}{M+m}$$

Substitute numerical values and evaluate x:

$$x = \frac{(5.0\text{ m})(300\,\text{kg})}{300\,\text{kg} + 60.0\,\text{kg}} = \boxed{4.2\,\text{m}}$$

19 •• **[SSM]** A *gravity board* is a convenient and quick way to determine the location of the center of gravity of a person. It consists of a horizontal board supported by a fulcrum at one end and a scale at the other end. To demonstrate this in class, your physics professor calls on you to lie horizontally on the board with the top of your head directly above the fulcrum point as shown in Figure 12-33. The scale is 2.00 m from the fulcrum. In preparation for this experiment, you had accurately weighed yourself and determined your mass to be 70.0 kg. When you are at rest on the gravity board, the scale advances 250 N beyond its reading when the board is there by itself. Use this data to determine the location of your center of gravity relative to your feet.

Picture the Problem The diagram shows $\vec{w}$, the weight of the student, $\vec{F}_P$, the force exerted by the board at the pivot, and $\vec{F}_s$, the force exerted by the scale, acting on the student. Because the student is in equilibrium, we can apply the condition for rotational equilibrium to the student to find the location of his center of gravity.



Apply $\sum \vec{\tau} = 0$ about an axis through the pivot point *P*:

$$F_s(2.00\,\text{m}) - wx = 0$$

Solving for *x* yields:

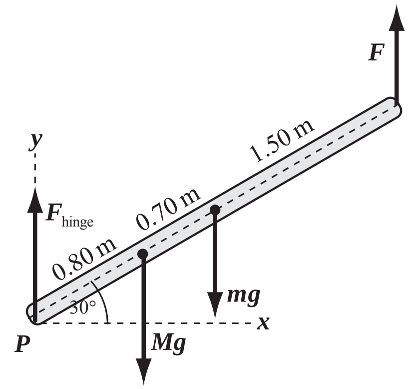
$$x = \frac{(2.00\,\text{m})F_s}{w}$$

Substitute numerical values and evaluate *x*:

$$x = \frac{(2.00\,\text{m})(250\,\text{N})}{(70.0\,\text{kg})(9.81\,\text{m/s}^2)} = \boxed{0.728\,\text{m}}$$

20 •• A stationary 3.0-m board of mass 5.0 kg is hinged at one end. A force $\vec{F}$ is applied vertically at the other end, and the board makes at 30° angle with the horizontal. A 60-kg block rests on the board 80 cm from the hinge as shown in Figure 12-34. (*a*) Find the magnitude of the force $\vec{F}$. (*b*) Find the force exerted by the hinge. (*c*) Find the magnitude of the force $\vec{F}$, as well as the force exerted by the hinge, if $\vec{F}$ is exerted, instead, at right angles to the board.

Picture the Problem The diagram shows $m\vec{g}$, the weight of the board, $\vec{F}_{\text{hinge}}$, the force exerted by the hinge, $M\vec{g}$, the weight of the block, and $\vec{F}$, the force acting vertically at the right end of the board. Because the board is in equilibrium, we can apply the condition for rotational equilibrium to it to find the magnitude of $\vec{F}$.



(a) Apply $\sum \vec{\tau} = 0$ about an axis through the hinge to obtain:

$$F[(3.0\,\text{m})\cos 30°] - mg[(1.50\,\text{m})\cos 30°] - Mg[(0.80\,\text{m})\cos 30°] = 0$$

Solving for F yields:

$$F = \frac{m(1.50\,\text{m}) + M(0.80\,\text{m})}{3.0\,\text{m}} g$$

Substitute numerical values and evaluate F:

$$F = \frac{(5.0\,\text{kg})(1.50\,\text{m}) + (60\,\text{kg})(0.80\,\text{m})}{3.0\,\text{m}}(9.81\,\text{m/s}^2) = 181\,\text{N} = \boxed{0.181\,\text{kN}}$$

Apply $\sum F_y = 0$ to the board to obtain:

$$F_{\text{hinge}} - Mg - mg + F = 0$$

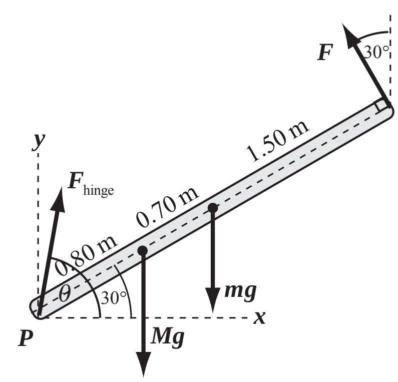
Solving for F_{hinge} yields:

$$F_{\text{hinge}} = Mg + mg - F = (M + m)g - F$$

Substitute numerical values and evaluate F_{hinge}:

$$F_{\text{hinge}} = (60\,\text{kg} + 5.0\,\text{kg})(9.81\,\text{m/s}^2) - 181\,\text{N} = \boxed{0.46\,\text{kN}}$$

(c) The force diagram showing the force $\vec{F}$ acting at right angles to the board is shown to the right:



Apply $\sum \vec{\tau} = 0$ about the hinge:

$$F(3.0\,\text{m}) - mg[(1.5\,\text{m})\cos 30°] - Mg[(0.80\,\text{m})\cos 30°] = 0$$

Solving for F yields:

$$F = \frac{m(1.5\,\text{m}) + M(0.80\,\text{m})}{3.0\,\text{m}} g\cos 30°$$

Substitute numerical values and evaluate F:

$$F = \frac{(5.0\,\text{kg})(1.5\,\text{m}) + (60\,\text{kg})(0.80\,\text{m})}{3.0\,\text{m}}(9.81\,\text{m/s}^2)\cos 30° = 157\,\text{N} = \boxed{0.16\,\text{kN}}$$

Apply $\sum F_y = 0$ to the board:

$$F_{\text{hinge}} \sin\theta - Mg - mg + F\cos 30° = 0$$

or

$$F_{\text{hinge}} \sin\theta = (M + m)g - F\cos 30° \quad (1)$$

Apply $\sum F_x = 0$ to the board:

$$F_{\text{hinge}} \cos\theta - F\sin 30° = 0$$

or

$$F_{\text{hinge}} \cos\theta = F\sin 30° \quad (2)$$

Divide the first of these equations by the second to obtain:

$$\frac{F_{\text{hinge}} \sin\theta}{F_{\text{hinge}} \cos\theta} = \frac{(M + m)g - F\cos 30°}{F\sin 30°}$$

Solving for θ yields:

$$\theta = \tan^{-1}\left[\frac{(M + m)g - F\cos 30°}{F\sin 30°}\right]$$

Substitute numerical values and evaluate θ:

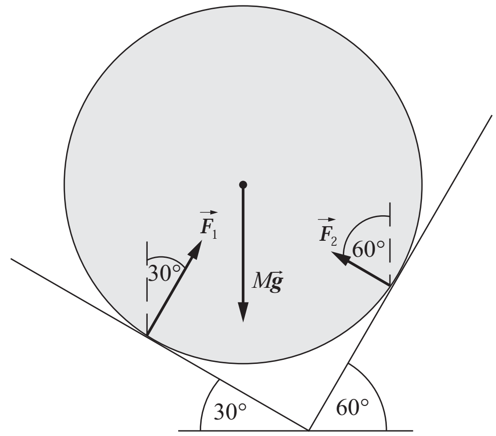
$$\theta = \tan^{-1}\left[\frac{(65\,\text{kg})(9.81\,\text{m/s}^2) - (157\,\text{N})\cos 30°}{(157\,\text{N})\sin 30°}\right] = 81.1°$$

Substitute numerical values in equation (2) and evaluate F_{hinge}:

$$F_{\text{hinge}} = \frac{(157\,\text{N})\sin 30°}{\cos 81.1°} = \boxed{0.51\,\text{kN}}$$

21 •• A cylinder of mass M is supported by a frictionless trough formed by a plane inclined at 30º to the horizontal on the left and one inclined at 60º on the right as shown in Figure 12-35. Find the force exerted by each plane on the cylinder.

Picture the Problem The planes are frictionless; therefore, the force exerted by each plane must be perpendicular to that plane. Let $\vec{F}_1$ be the force exerted by the 30° plane, and let $\vec{F}_2$ be the force exerted by the 60° plane. Choose a coordinate system in which the +*x* direction is to the right and the +*y* direction is upward. Because the cylinder is in equilibrium, we can use the conditions for translational equilibrium to find the magnitudes of $\vec{F}_1$ and $\vec{F}_2$.



Apply $\sum F_x = 0$ to the cylinder: $$F_1 \sin 30° - F_2 \sin 60° = 0 \quad (1)$$

Apply $\sum F_y = 0$ to the cylinder: $$F_1 \cos 30° + F_2 \cos 60° - W = 0 \quad (2)$$

Solve equation (1) for F_1: $$F_1 = \sqrt{3} F_2 \quad (3)$$

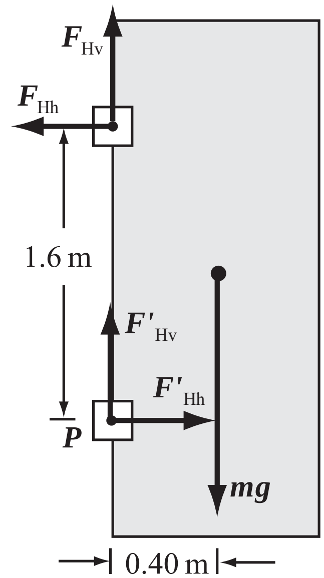
Substituting for F_1 in equation (2) yields: $$\sqrt{3} F_2 \cos 30° + F_2 \cos 60° - W = 0$$

Solving for F_2 gives: $$F_2 = \frac{W}{\sqrt{3}\cos 30° + \cos 60°} = \boxed{\tfrac{1}{2}W}$$

Substitute for F_2 in equation (3) to obtain: $$F_1 = \sqrt{3}\left(\tfrac{1}{2}W\right) = \boxed{\tfrac{\sqrt{3}}{2}W}$$

22 •• A uniform 18-kg door that is 2.0 m high by 0.80 m wide is hung from two hinges that are 20 cm from the top and 20 cm from the bottom. If each hinge supports half the weight of the door, find the magnitude and direction of the horizontal components of the forces exerted by the two hinges on the door.

Picture the Problem The drawing shows the door and its two supports. The center of gravity of the door is 0.80 m above (and below) the hinge, and 0.40 m from the hinges horizontally. Choose a coordinate system in which the +*x* direction is to the right and the +*y* direction is upward. Denote the horizontal and vertical components of the hinge force by F_{Hh} and F_{Hv}. Because the door is in equilibrium, we can use the conditions for translational and rotational equilibrium to determine the horizontal forces exerted by the hinges.



Apply $\sum\vec{\tau} = 0$ about an axis through the lower hinge:

$$F_{\text{Hh}}(1.6\,\text{m}) - mg(0.40\,\text{m}) = 0$$

Solve for F_{Hh}:

$$F_{\text{Hh}} = \frac{mg(0.40\,\text{m})}{1.6\,\text{m}}$$

Substitute numerical values and evaluate F_{Hh}:

$$F_{\text{Hh}} = \frac{(18\,\text{kg})(9.81\,\text{m/s}^2)(0.40\,\text{m})}{1.6\,\text{m}} = \boxed{44\,\text{N}}$$

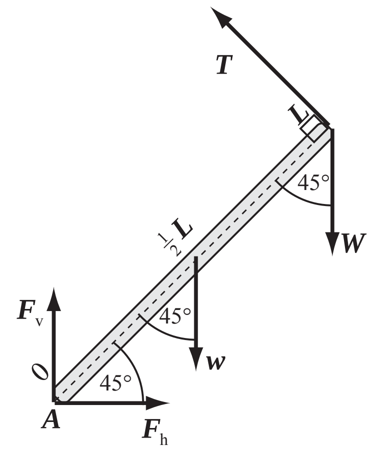
Apply $\sum F_x = 0$ to the door and solve for F'_{Hh}:

$$F'_{\text{Hh}} - F_{\text{Hh}} = 0$$
and
$$F'_{\text{Hh}} = \boxed{44\,\text{N}}$$

Remarks: Note that the upper hinge pulls on the door and the lower hinge pushes on it.

23 •• Find the force exerted on the strut by the hinge at A for the arrangement in Figure 12-36 if (*a*) the strut is weightless, and (*b*) the strut weighs 20 N.

Picture the Problem Let T be the tension in the line attached to the wall and L be the length of the strut. The figure includes w, the weight of the strut, for Part (b). Because the strut is in equilibrium, we can use the conditions for both rotational and translational equilibrium to find the force exerted on the strut by the hinge.



(a) Express the force exerted on the strut at the hinge:

$$\vec{F} = F_h\hat{i} + F_v\hat{j} \qquad (1)$$

Ignoring the weight of the strut, apply $\sum\vec{\tau} = 0$ at the hinge:

$$LT - (L\cos 45°)W = 0$$

Solve for the tension in the line:

$$T = W\cos 45° = (60\,\text{N})\cos 45° = 42.4\,\text{N}$$

Apply $\sum\vec{F} = 0$ to the strut:

$$\sum F_x = F_h - T\cos 45° = 0$$

and

$$\sum F_y = F_v + T\cos 45° - Mg = 0$$

Solve for and evaluate F_h:

$$F_h = T\cos 45° = (42.4\,\text{N})\cos 45° = 30\,\text{N}$$

Solve for and evaluate F_v:

$$F_v = Mg - T\cos 45° = 60\,\text{N} - (42.4\,\text{N})\cos 45° = 30\,\text{N}$$

Substitute in equation (1) to obtain:

$$\vec{F} = \boxed{(30\,\text{N})\hat{i} + (30\,\text{N})\hat{j}}$$

(b) Including the weight of the strut, apply $\sum\vec{\tau} = 0$ at the hinge:

$$LT - (L\cos 45°)W - \left(\frac{L}{2}\cos 45\right)w = 0$$

Solve for the tension in the line:

$$T = (\cos 45°)W + \left(\frac{1}{2}\cos 45°\right)w$$

Substitute numerical values and evaluate T:

$$T = (\cos 45°)(60\,\text{N}) + \left(\frac{1}{2}\cos 45°\right)(20\,\text{N}) = 49.5\,\text{N}$$

Apply $\sum \vec{F} = 0$ to the strut:

$$\sum F_x = F_\text{h} - T\cos 45° = 0$$

and

$$\sum F_y = F_\text{v} + T\cos 45° - W - w = 0$$

Solve for and evaluate F_h:

$$F_\text{h} = T\cos 45° = (49.5\,\text{N})\cos 45° = 35\,\text{N}$$

Solve for and evaluate F_v:

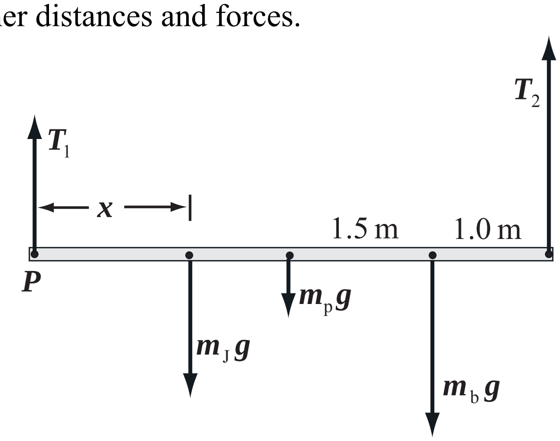
$$F_\text{v} = W + w - T\cos 45° = 60\,\text{N} + 20\,\text{N} - (49.5\,\text{N})\cos 45° = 45\,\text{N}$$

Substitute for F_h and F_v in equation (1) to obtain:

$$\vec{F} = \boxed{(35\,\text{N})\hat{\boldsymbol{i}} + (45\,\text{N})\hat{\boldsymbol{j}}}$$

24 •• Julie has been hired to help paint the trim of a building, but she is not convinced of the safety of the apparatus. A 5.0-m plank is suspended horizontally from the top of the building by ropes attached at each end. Julie knows from previous experience that the ropes being used will break if the tension exceeds 1.0 kN. Her 80-kg boss dismisses Julie's worries and begins painting while standing 1.0 m from the end of the plank. If Julie's mass is 60 kg and the plank has a mass of 20 kg, then over what range of positions can Julie stand to join her boss without causing the ropes to break?

Picture the Problem Note that if Julie is at the far left end of the plank, T_1 and T_2 are less than 1.0 kN. Let x be the distance of Julie from T_1. Because the plank is in equilibrium, we can apply the condition for rotational equilibrium to relate the distance x to the other distances and forces.



Apply $\sum\vec{\tau} = 0$ about an axis through the left end of the plank:

$$(5.0\,\text{m})T_2 - (4.0\,\text{m})m_\text{b}g - (2.5\,\text{m})m_\text{p}g - m_\text{J}gx = 0$$

Solving for x yields:

$$x = \frac{(5.0\,\text{m})T_2}{m_\text{J}g} - \frac{(4.0\,\text{m})m_\text{b}}{m_\text{J}} - \frac{(2.5\,\text{m})m_\text{p}}{m_\text{J}}$$

Substitute numerical values and simplify to obtain:

$$\boldsymbol{x} = \left(8.495\times10^{-3}\,\frac{\text{m}}{\text{N}}\right)\boldsymbol{T}_2 - 6.17\text{ m}$$

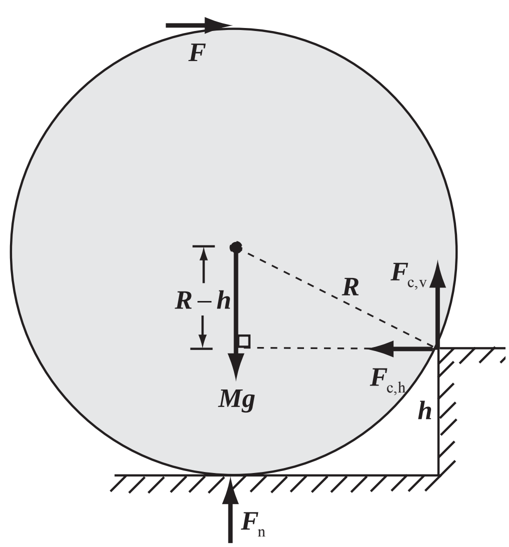
Set $T_2 = 1.0$ kN and evaluate x:

$$\boldsymbol{x} = \left(8.495\times10^{-3}\,\frac{\text{m}}{\text{N}}\right)(1.0\,\text{kN}) - 6.17\text{ m} = 2.3\,\text{m}$$

and Julie is safe provided $\boxed{\boldsymbol{x} < 2.3\,\text{m.}}$

25 •• **[SSM]** A cylinder of mass M and radius R rolls against a step of height h as shown in Figure 12-37. When a horizontal force of magnitude F is applied to the top of the cylinder, the cylinder remains at rest. (a) Find an expression for the normal force exerted by the floor on the cylinder. (b) Find an expression for the horizontal force exerted by the edge of the step on the cylinder. (c) Find an expression for the vertical component of the force exerted by the edge of the step on the cylinder.

Picture the Problem The figure to the right shows the forces acting on the cylinder. Choose a coordinate system in which the $+x$ direction is to the right and the $+y$ direction is upward. Because the cylinder is in equilibrium, we can apply the conditions for translational and rotational equilibrium to find F_n and the horizontal and vertical components of the force the corner of the step exerts on the cylinder.



(a) Apply $\sum\vec{\tau} = 0$ to the cylinder about the step's corner:

$$Mg\ell - F_\text{n}\ell - F(2R - h) = 0$$

Solving for F_n yields:

$$F_n = Mg - \frac{F(2R-h)}{\ell}$$

Express ℓ as a function of R and h:

$$\ell = \sqrt{R^2 - (R-h)^2} = \sqrt{2Rh - h^2}$$

Substitute for ℓ in the expression for F_n and simplify to obtain:

$$F_n = Mg - \frac{F(2R-h)}{\sqrt{2Rh-h^2}} = \boxed{Mg - F\sqrt{\frac{2R-h}{h}}}$$

(*b*) Apply $\sum F_x = 0$ to the cylinder:

$$-F_{c,h} + F = 0$$

Solve for $F_{c,h}$:

$$F_{c,h} = \boxed{F}$$

(*c*) Apply $\sum F_y = 0$ to the cylinder:

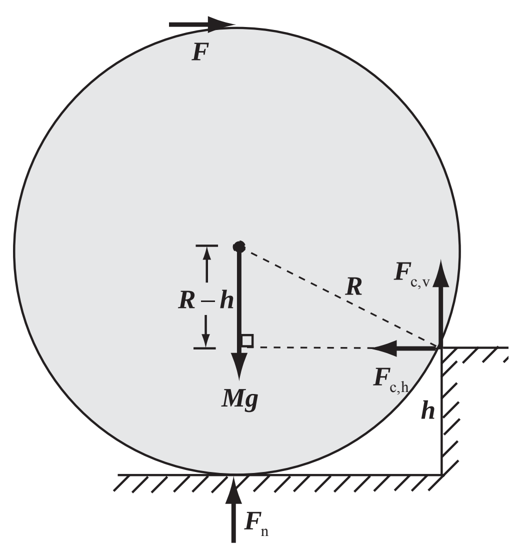
$$F_n - Mg + F_{c,v} = 0 \Rightarrow F_{c,v} = Mg - F_n$$

Substitute the result from Part (*a*) and simplify to obtain:

$$F_{c,v} = Mg - \left\{Mg - F\sqrt{\frac{2R-h}{h}}\right\} = \boxed{F\sqrt{\frac{2R-h}{h}}}$$

26 •• For the cylinder in Problem 25, find an expression for the minimum magnitude of the horizontal force $\vec{F}$ that will roll the cylinder over the step if the cylinder does not slide on the edge.

Picture the Problem The figure to the right shows the forces acting on the cylinder. Because the cylinder is in equilibrium, we can use the condition for rotational equilibrium to express F_n in terms of F. Because, to roll over the step, the cylinder must lift off the floor, we can set $F_n = 0$ in our expression relating F_n and F and solve for F.



Apply $\sum \vec{\tau} = 0$ about the step's corner:

$$Mg\ell - F_\text{n}\ell - F(2R - h) = 0$$

Solve for F_n:

$$F_\text{n} = Mg - \frac{F(2R-h)}{\ell}$$

Express ℓ as a function of R and h:

$$\ell = \sqrt{R^2 - (R-h)^2} = \sqrt{2Rh - h^2}$$

Substitute for ℓ in the expression for F_n and simplify to obtain:

$$F_\text{n} = Mg - \frac{F(2R-h)}{\sqrt{2Rh - h^2}} = Mg - F\sqrt{\frac{2R-h}{h}}$$

To roll over the step, the cylinder must lift off the floor. That is, $F_\text{n} = 0$:

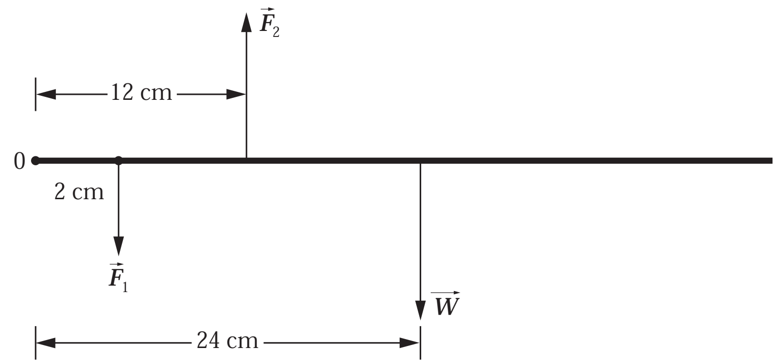
$$0 = Mg - F\sqrt{\frac{2R-h}{h}}$$

Solving for F yields:

$$F = \boxed{Mg\sqrt{\frac{h}{2R-h}}}$$

27 •• Figure 12-38 shows a hand holding an epee, a weapon used in the sport of fencing which you are taking as a physical education elective. The center of mass of your epee is 24 cm from the pommel (the end of the epee at the grip). You have weighed it so you know that the epee's mass is 0.700 kg and its full length is 110 cm. (*a*) At the beginning of a match you hold it straight out in static equilibrium. Find the total force exerted by your hand on the epee. (*b*) Find the torque exerted by your hand on the epee. (*c*) Your hand, being an extended object, actually exerts its force along the length of the epee grip. Model the total force exerted by your hand as two oppositely directed forces whose lines of action are separated by the width of your hand (taken to be 10.0 cm). Find the magnitudes and directions of these two forces.

Picture the Problem The diagram shows the forces F_1 and F_2 that the fencer's hand exerts on the epee. We can use a condition for translational equilibrium to find the upward force the fencer must exert on the epee when it is in equilibrium and the definition of torque to determine the total torque exerted. In Part (*c*) we can use the conditions for translational and rotational equilibrium to obtain two equations in F_1 and F_2 that we can solve simultaneously. In Part (*d*) we can apply Newton's second law in rotational form and the condition for translational equilibrium to obtain two equations in F_1 and F_2 that, again, we can solve simultaneously.



(a) Letting the upward force exerted by the fencer's hand be F, apply $\sum F_y = 0$ to the epee to obtain:

$F - W = 0$
and
$F = W = mg$

Substitute numerical values and evaluate F:

$$F = (0.700\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{6.87\,\text{N}}$$

(b) The torque due to the weight about the left end of the epee is equal in magnitude but opposite in direction to the torque exerted by your hand on the epee:

$$\tau = \ell w$$

Substitute numerical values and evaluate τ:

$$\tau = (0.24\,\text{m})(6.87\,\text{N}) = 1.65\,\text{N}\cdot\text{m} = \boxed{1.7\,\text{N}\cdot\text{m}}$$

(c) Apply $\sum F_y = 0$ to the epee to obtain:

$$-F_1 + F_2 - 6.87\,\text{N} = 0 \qquad (1)$$

Apply $\sum \vec{\tau}_0 = 0$ to obtain:

$$-(0.020\,\text{m})F_1 + (0.12\,\text{m})F_2 - 1.65\,\text{N}\cdot\text{m} = 0 \qquad (2)$$

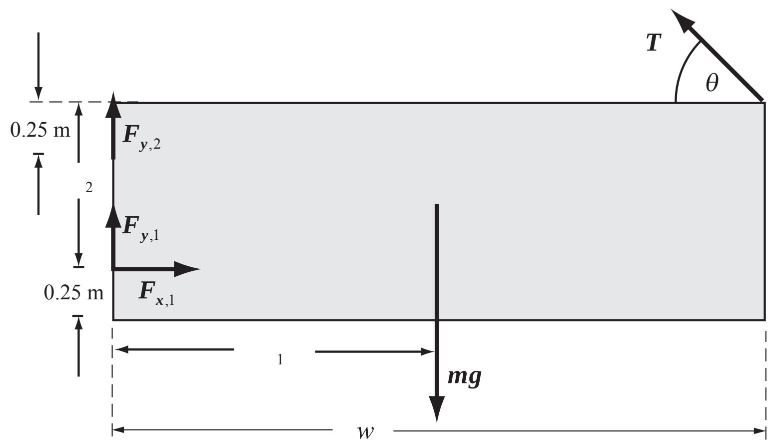
Solve equations (1) and (2) simultaneously to obtain:

$$F_1 = \boxed{8.3\,\text{N}} \text{ and } F_2 = \boxed{15\,\text{N}}.$$

Remarks: Note that the force nearest the butt of the epee is directed downward and the force nearest the hand guard is directed upward.

28 •• A large gate weighing 200 N is supported by hinges at the top and bottom and is further supported by a wire as shown in Figure 12-39. (a) What must be the tension in the wire for the force on the upper hinge to have no horizontal component? (b) What is the horizontal force on the lower hinge? (c) What are the vertical forces on the hinges?

Picture the Problem In the force diagram, the forces exerted by the hinges are $\vec{F}_{y,2}$, $\vec{F}_{y,1}$, and $\vec{F}_{x,1}$ where the subscript 1 refers to the lower hinge. Because the gate is in equilibrium, we can apply the conditions for translational and rotational equilibrium to find the tension in the wire and the forces at the hinges.



(*a*) Apply $\sum\vec{\tau} = 0$ about an axis through the lower hinge and perpendicular to the plane of the page:

$$wT\sin\theta + \ell_2 T\cos\theta - \ell_1 mg = 0$$

Solving for T yields:

$$T = \frac{\ell_1 mg}{w\sin\theta + \ell_2\cos\theta}$$

From Figure 12-39:

$$\theta = \tan^{-1}\left(\frac{1.50\ \text{m}}{3.00\ \text{m}}\right) = 26.57°$$

Substitute numerical values and evaluate T:

$$T = \frac{(1.50\,\text{m})(200\,\text{N})}{(3.00\,\text{m})\sin 26.57° + (0.75\,\text{m})\cos 26.57°} = 149.1\,\text{N} = \boxed{149\ \text{N}}$$

(*b*) Apply $\sum F_x = 0$ to the gate:

$$F_{x,1} - T\cos\theta = 0 \Rightarrow F_{x,1} = T\cos\theta$$

Substitute numerical values and evaluate $F_{x,1}$:

$$F_{x,1} = (149.1\,\text{N})\cos 26.57°$$
$$= 133.4\ \text{N} = \boxed{133\,\text{N}}$$

(*c*) Apply $\sum F_y = 0$ to the gate:

$$F_{y,1} + F_{y,2} + T\sin\theta - mg = 0$$

Because $F_{y,1}$ and $F_{y,2}$ cannot be determined independently, solve for their sum:

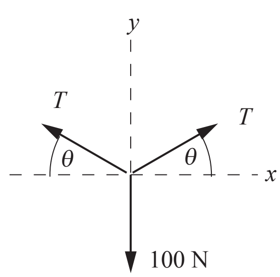
$$F_{y,1} + F_{y,2} = mg - T\sin\theta$$

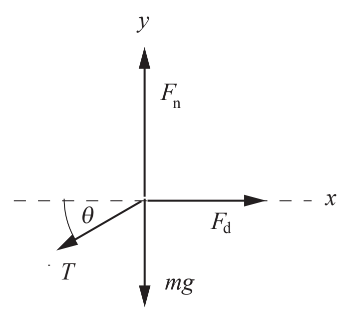
Substitute numerical values and evaluate $F_{y,1} + F_{y,2}$:

$$F_{y,1} + F_{y,2} = 200\text{ N} - (149.1\text{ N})\sin 26.57° = \boxed{133\text{ N}}$$

29 •• On a camping trip, you moor your boat at the end of a dock in a river that is rapidly flowing to the right. The boat is anchored to the dock by a chain 5.0 m long, as shown in Figure 12-40. A 100-N weight is suspended from the center in the chain. This will allow the tension in the chain to change as the force of the current which pulls the boat away from the dock and to the right varies. The drag force by the water on the boat depends on the speed of the water. You decide to apply the principles of statics you learned in physics class. (Ignore the weight of the chain.) The drag force on the boat is 50 N. (*a*) What is the tension in the chain? (*b*) How far is the boat from the dock? (*c*) The maximum tension the chain can sustain is 500 N. What is the minimum water drag force on the boat would snap the chain?

Picture the Problem The free-body diagram shown to the left below is for the weight and the diagram to the right is for the boat. Because both are in equilibrium under the influences of the forces acting on them, we can apply a condition for translational equilibrium to find the tension in the chain.





(*a*) Apply $\sum F_x = 0$ to the boat:

$$F_d - T\cos\theta = 0 \Rightarrow T = \frac{F_d}{\cos\theta}$$

Apply $\sum F_y = 0$ to the weight:

$$2T\sin\theta - 100\text{ N} = 0 \qquad (1)$$

Substitute for T to obtain:

$$2F_d \tan\theta - 100\text{ N} = 0$$

Solve for θ to obtain:

$$\theta = \tan^{-1}\left[\frac{100\text{ N}}{2F_d}\right]$$

Substitute for F_d and evaluate θ:

$$\theta = \tan^{-1}\left[\frac{100\,\text{N}}{2(50\,\text{N})}\right] = 45°$$

Solve equation (1) for T:

$$T = \frac{100\,\text{N}}{2\sin\theta}$$

Substitute for θ and evaluate T:

$$T = \frac{100\,\text{N}}{2\sin 45°} = 70.7\,\text{N} = \boxed{71\,\text{N}}$$

(b) Relate the distance d of the boat from the dock to the angle θ the chain makes with the horizontal:

$$\cos\theta = \frac{\frac{1}{2}d}{\frac{1}{2}L} = \frac{d}{L} \Rightarrow d = L\cos\theta$$

Substitute numerical values and evaluate d:

$$d = (5.0\,\text{m})\cos 45° = \boxed{3.5\,\text{m}}$$

(c) Relate the resultant tension in the chain to the vertical component of the tension F_v and the maximum drag force exerted on the boat by the water $F_{d,max}$:

$$F_v^2 + F_{d,max}^2 = (500\,\text{N})^2$$

Solve for $F_{d,max}$:

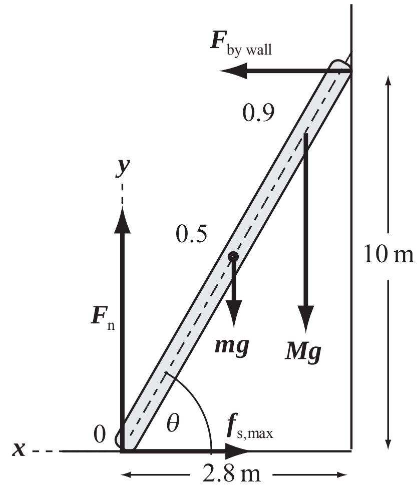
$$F_{d,max} = \sqrt{(500\,\text{N})^2 - F_v^2}$$

Because the vertical component of the tension is 50 N:

$$F_{d,max} = \sqrt{(500\,\text{N})^2 - (50\,\text{N})^2} = \boxed{0.50\,\text{kN}}$$

30 •• Romeo takes a uniform 10-m ladder and leans it against the smooth (frictionless) wall of the Capulet residence. The ladder's mass is 22 kg and the bottom rests on the ground 2.8 m from the wall. When Romeo, whose mass is 70 kg, gets 90 percent of the way to the top, the ladder begins to slip. What is the coefficient of static friction between the ground and the ladder?

Picture the Problem The ladder and the forces acting on it at the critical moment of slipping are shown in the diagram. Use the coordinate system shown. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Using its definition, express μ_s:

$$\mu_s = \frac{f_{s,max}}{F_n} \qquad (1)$$

Apply $\sum \vec{\tau} = 0$ about the bottom of the ladder:

$$[0.9\ell\cos\theta]Mg + [0.5\ell\cos\theta]mg - [\ell\sin\theta]F_W = 0$$

Solving for F_W yields:

$$F_W = \frac{(0.9M + 0.5m)g\cos\theta}{\sin\theta}$$

Find the angle θ:

$$\theta = \cos^{-1}\left(\frac{2.8\,\text{m}}{10\,\text{m}}\right) = 73.74°$$

Substitute numerical values and evaluate F_W:

$$F_W = \frac{[0.9(70\,\text{kg}) + 0.5(22\,\text{kg})](9.81\,\text{m/s}^2)\cos 73.74°}{\sin 73.74°} = 211.7\,\text{N}$$

Apply $\sum F_x = 0$ to the ladder and solve for $f_{s,max}$:

$$F_W - f_{s,max} = 0$$

and

$$f_{s,max} = F_W = 211.7\,\text{N}$$

Apply $\sum F_y = 0$ to the ladder:

$$F_n - Mg - mg = 0 \Rightarrow F_n = (M + m)g$$

Substitute numerical values and evaluate F_n:

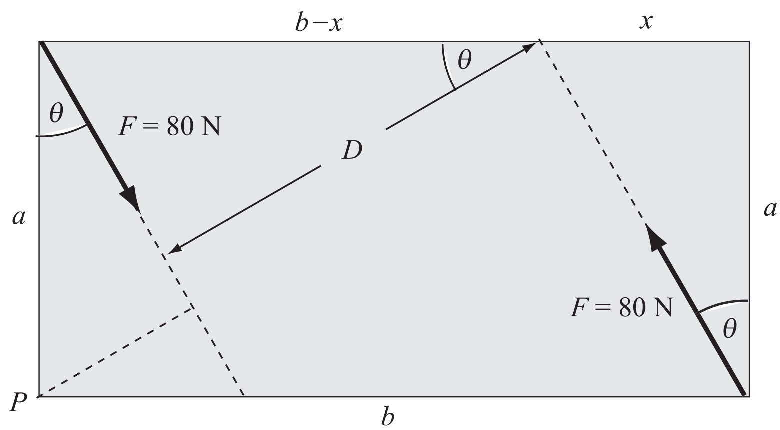
$$F_n = (70\,\text{kg} + 22\,\text{kg})(9.81\,\text{m/s}^2) = 902.5\,\text{N}$$

Substitute numerical values in equation (1) and evaluate μ_s:

$$\mu_s = \frac{211.7\,\text{N}}{902.5\,\text{N}} = \boxed{0.23}$$

31 •• [SSM] Two 80-N forces are applied to opposite corners of a rectangular plate as shown in Figure 12-41. (*a*) Find the torque produced by this couple using Equation 12-6. (*b*) Show that the result is the same as if you determine the torque about the lower left-hand corner.

Picture the Problem The forces shown in the figure constitute a couple and will cause the plate to experience a counterclockwise angular acceleration. The couple equation is $\tau = FD$. The following diagram shows the geometric relationships between the variables in terms of a generalized angle θ.



(*a*) The couple equation is: $\tau = FD$ (1)

From the diagram, D is given by: $D = (b - x)\cos\theta$ (2)

Again, referring to the diagram: $x = a\tan\theta$

Substituting for x in equation (2) and simplifying yields:

$$D = (b - a\tan\theta)\cos\theta$$
$$= b\cos\theta - a\sin\theta$$

Substituting for D in equation (1) yields: $\tau = F(b\cos\theta - a\sin\theta)$ (3)

Substitute numerical values and evaluate τ:

$$\tau = (80\,\text{N})(b\cos 30° - a\sin 30°)$$
$$= \boxed{(69\,\text{N})b - (40\,\text{N})a}$$

(*b*) Letting the counterclockwise direction be the positive direction, sum the torques about an axis normal to the plane of the rectangle and passing through point *P*:

$$\tau = F(\ell + D) - F\ell$$

Substituting for *D* yields:

$$\tau = F(\ell + b\cos\theta - a\sin\theta) - F\ell$$
$$= \boxed{F(b\cos\theta - a\sin\theta)}$$

in agreement with equation (3).

32 •• A uniform cube of side *a* and mass *M* rests on a horizontal surface. A horizontal force $\vec{F}$ is applied to the top of the cube as in Figure 12-42. This force is not sufficient to move or tip the cube. (*a*) Show that the force of static friction exerted by the surface and the applied force constitute a couple, and find the torque exerted by the couple. (*b*) The torque exerted by the couple is balanced by the torque exerted by the couple consisting of the normal force on the cube and the gravitational force on the cube. Use this fact to find the effective point of application of the normal force when $F = Mg/3$. (*c*) Find the greatest magnitude of $\vec{F}$ for which the cube will not tip (Assuming the cube does not slip.).

Picture the Problem We can use the condition for translational equilibrium and the definition of a couple to show that the force of static friction exerted by the surface and the applied force constitute a couple. We can use the definition of torque to find the torque exerted by the couple. We can use our result from (*b*) to find the effective point of application of the normal force when $F = Mg/3$ and the condition for rotational equilibrium to find the greatest magnitude of $\vec{F}$ for which the cube will not tip.

(*a*) Apply $\sum \vec{F}_x = 0$ to the stationary cube:

$$\vec{F} + \vec{f}_s = 0 \Rightarrow \vec{F} = -\vec{f}_s$$

Because $\vec{F} = -\vec{f}_s$, this pair of equal, parallel, and oppositely directed forces constitute a couple.

The torque of the couple is:

$$\tau_{\text{couple}} = \boxed{Fa}$$

(*b*) Let x equal the distance from the point of application of F_n to the center of the cube. Now, $F_n = Mg$, so applying $\sum \vec{\tau} = 0$ to the cube yields:

$$Mgx - Fa = 0 \Rightarrow x = \frac{Fa}{Mg} \qquad (1)$$

Substituting for F and simplifying yields:

$$x = \frac{\frac{Mg}{3}a}{Mg} = \boxed{\frac{a}{3}}$$

(*c*) Solve equation (1) for F:

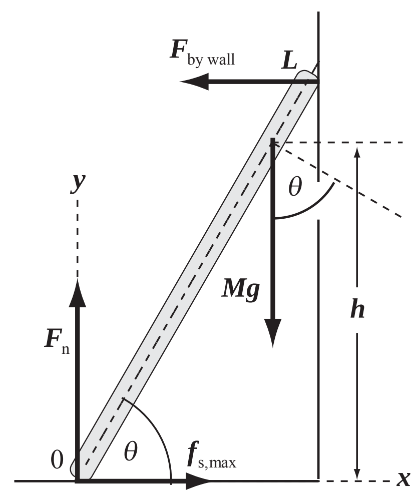
$$F = \frac{Mgx}{a}$$

Noting that $x_{max} = a/2$, express the condition that the cube will tip:

$$F > \frac{Mgx_{max}}{a} = \frac{Mg\frac{a}{2}}{a} = \boxed{\frac{Mg}{2}}$$

33 •• **[SSM]** A ladder of negligible mass and of length L leans against a slick wall making an angle of θ with the horizontal floor. The coefficient of friction between the ladder and the floor is μ_s. A man climbs the ladder. What height h can he reach before the ladder slips?

Picture the Problem Let the mass of the man be M. The ladder and the forces acting on it are shown in the diagram. Because the wall is slick, the force the wall exerts on the ladder must be horizontal. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium to it.



Apply $\sum F_y = 0$ to the ladder and solve for F_n:

$$F_n - Mg = 0 \Rightarrow F_n = Mg$$

Apply $\sum F_x = 0$ to the ladder and solve for $f_{s,max}$:

$$f_{s,max} - F_W = 0 \Rightarrow f_{s,max} = F_W$$

Apply $\sum \vec{\tau} = 0$ about the bottom of the ladder to obtain:

$$Mg\ell\cos\theta - F_W L\sin\theta = 0$$

Solving for ℓ and simplifying yields:

$$\ell = \frac{F_W L\sin\theta}{Mg\cos\theta} = \frac{f_{s,max}L}{Mg}\tan\theta$$
$$= \frac{\mu_s F_n L}{Mg}\tan\theta = \mu_s L\tan\theta$$

Referring to the figure, relate ℓ to h:

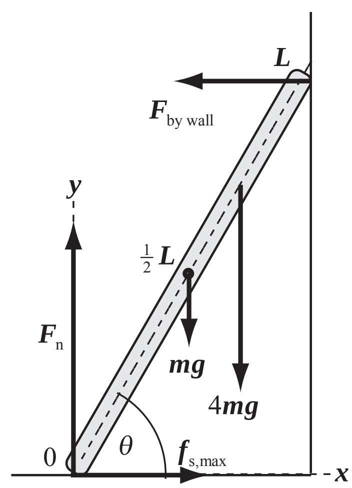
$$h = \ell\sin\theta$$

Substituting for ℓ yields:

$$h = \boxed{\mu_s L\tan\theta\sin\theta}$$

34 •• A uniform ladder of length L and mass m leans against a frictionless vertical wall, making an angle of 60º with the horizontal. The coefficient of static friction between the ladder and the ground is 0.45. If your mass is four times that of the ladder, how high can you climb before the ladder begins to slip?

Picture the Problem The ladder and the forces acting on it are shown in the drawing. Choose a coordinate system in which the $+x$ direction is to the right and the $+y$ direction is upward. Because the wall is smooth, the force the wall exerts on the ladder must be horizontal. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Apply $\sum F_y = 0$ to the ladder and solve for F_n:

$$F_n - mg - 4mg = 0 \Rightarrow F_n = 5mg$$

Apply $\sum F_x = 0$ to the ladder and solve for $f_{s,max}$:

$$F_W - f_{s,max} = 0 \Rightarrow f_{s,max} = F_W$$

Apply $\sum \vec{\tau} = 0$ about an axis through the bottom of the ladder:

$$mg\frac{L}{2}\cos\theta + 4mg\ell\cos\theta - F_W L\sin\theta = 0$$

Substitute for F_W and $f_{s,max}$ and solve for ℓ:

$$\ell = \frac{5\mu_s mgL\sin\theta - \frac{1}{2}mgL\cos\theta}{4mg\cos\theta}$$

Simplify to obtain:

$$\ell = \left(\frac{5\mu_s}{4}\tan\theta - \frac{1}{8}\right)L$$

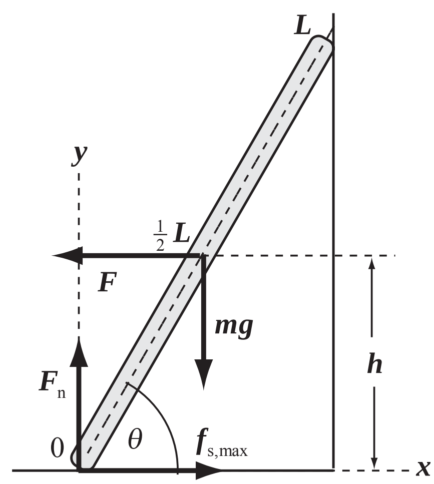
Substitute numerical values to obtain:

$$\ell = \left(\frac{5(0.45)}{4}\tan 60° - \frac{1}{8}\right)L = \boxed{0.85L}$$

That is, you can climb about 85% of the way to the top of the ladder before it begins to slip.

35 •• A ladder of mass m and length L leans against a frictionless vertical wall, so that it makes an angle θ with the horizontal. The center of mass of the ladder is a height h above the floor. A force F directed directly away from the wall pulls on the ladder at its midpoint. Find the minimum coefficient of static friction μ_s for which the top end of the ladder will separate from the wall before the lower end begins to slip.

Picture the Problem The ladder and the forces acting on it are shown in the figure. Because the ladder is separating from the wall, the force the wall exerts on the ladder is zero. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



To find the force required to pull the ladder away from the wall, apply $\sum\vec{\tau} = 0$ about an axis through the bottom of the ladder:

$$F\left(\tfrac{1}{2}L\sin\theta\right) - mg\left(\tfrac{1}{2}L\cos\theta\right) = 0$$

or, because $\frac{1}{2}L\cos\theta = \dfrac{h}{\tan\theta}$,

$$\tfrac{1}{2}LF\sin\theta - \frac{mgh}{\tan\theta} = 0$$

Solving for F yields:

$$F = \frac{2mgh}{L\tan\theta\sin\theta} \quad (1)$$

Apply $\sum F_x = 0$ to the ladder:

$$f_{s,max} - F = 0 \Rightarrow F = f_{s,max} = \mu_s F_n \quad (2)$$

Apply $\sum F_y = 0$ to the ladder: $F_n - mg = 0 \Rightarrow F_n = mg$

Equate equations (1) and (2) and substitute for F_n to obtain:

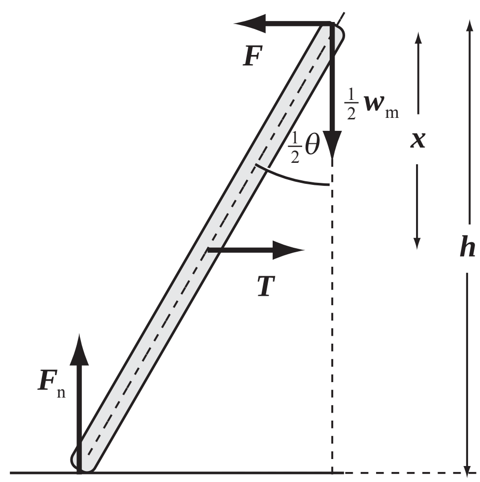
$$\mu_s mg = \frac{2mgh}{L\tan\theta\sin\theta}$$

Solving for μ_s yields:

$$\mu_s = \boxed{\frac{2h}{L\tan\theta\sin\theta}}$$

36 •• A 900-N man sits on top of a stepladder of negligible mass that rests on a frictionless floor as in Figure 12-43. There is a cross brace halfway up the ladder. The angle at the apex is θ = 30º. (*a*) What is the force exerted by the floor on each leg of the ladder? (*b*) Find the tension in the cross brace. (*c*) If the cross brace is moved down toward the bottom of the ladder (maintaining the same angle θ), will its tension be the same, greater, or less than when it was in its higher position? Explain your answer.

Picture the Problem Assume that half the man's weight acts on each side of the ladder. The force exerted by the frictionless floor must be vertical. D is the separation between the legs at the bottom and x is the distance of the cross brace from the apex. Because each leg of the ladder is in equilibrium, we can apply the condition for rotational equilibrium to the right leg to relate the tension in the cross brace to its distance from the apex.



(*a*) By symmetry, each leg carries half the total weight, and the force on each leg is $F_n = \frac{1}{2}w = \boxed{450\ \text{N}}$.

(*b*) Consider one of the ladder's legs and apply $\sum\vec{\tau} = 0$ about the apex:

$$F_n\frac{D}{2} - Tx = 0 \Rightarrow T = \frac{F_n D}{2x}$$

Using trigonometry, relate h and θ through the tangent function:

$$\tan\tfrac{1}{2}\theta = \frac{\frac{1}{2}D}{h} \Rightarrow D = 2h\tan\tfrac{1}{2}\theta$$

Substitute for D in the expression for T and simplify to obtain:

$$T = \frac{2F_n h\tan\frac{1}{2}\theta}{2x} = \frac{F_n h\tan\frac{1}{2}\theta}{x}$$

Substitute for F_n and simplify to obtain:

$$T = \frac{wh\tan\frac{1}{2}\theta}{2x} \quad (1)$$

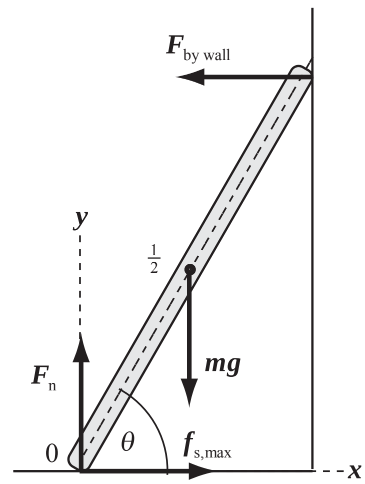
Substitute numerical values and evaluate T:

$$T = \frac{(900\,\text{N})(4.0\,\text{m})\tan 15°}{2(2.0\,\text{m})} = \boxed{0.24\,\text{kN}}$$

(c) From equation (1) we can see that T is inversely proportional to x. Hence, if the brace is moved lower, T will decrease.

37 •• A uniform ladder rests against a frictionless vertical wall. The coefficient of static friction between the ladder and the floor is 0.30. What is the smallest angle between the ladder and the horizontal such that the ladder will not slip?

Picture the Problem The figure shows the forces acting on the ladder. Because the wall is frictionless, the force the wall exerts on the ladder is perpendicular to the wall. Because the ladder is on the verge of slipping, the static friction force is $f_{s,max}$. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Apply $\sum F_x = 0$ to the ladder:

$$f_{s,max} - F_W = 0 \Rightarrow F_W = f_{s,max} = \mu_s F_n$$

Apply $\sum F_y = 0$ to the ladder:

$$F_n - mg = 0 \Rightarrow F_n = mg$$

Apply $\sum \vec{\tau} = 0$ about an axis through the bottom of the ladder:

$$mg\left(\tfrac{1}{2}\ell\cos\theta\right) - F_W(\ell\sin\theta) = 0$$

Substitute for F_W and F_n and simplify to obtain:

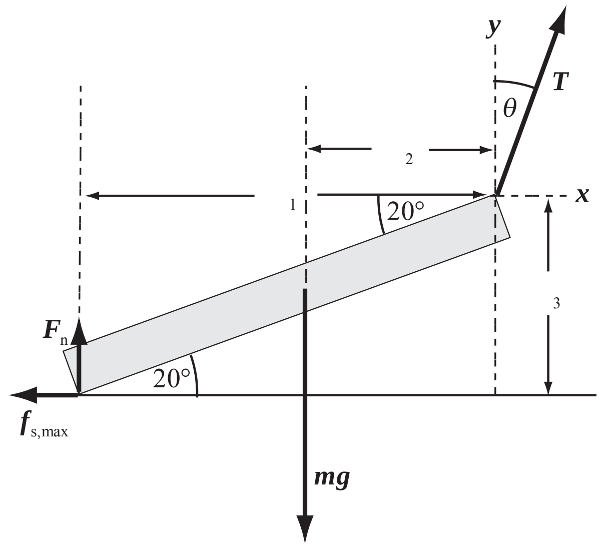
$$\tfrac{1}{2}\cos\theta - \mu_s\sin\theta = 0 \Rightarrow \theta = \tan^{-1}\left(\frac{1}{2\mu_s}\right)$$

Substitute the numerical value of μ_s and evaluate θ:

$$\theta = \tan^{-1}\left[\frac{1}{2(0.30)}\right] = \boxed{59°}$$

38 ••• A uniform log with a mass of 100 kg, a length of 4.0 m, and a radius of 12 cm is held in an inclined position, as shown in Figure 12-44. The coefficient of static friction between the log and the horizontal surface is 0.60. The log is on the verge of slipping to the right. Find the tension in the support wire and the angle the wire makes with the vertical wall.

Picture the Problem Let T = the tension in the wire; F_n = the normal force of the surface; and $f_{s,max} = \mu_s F_n$ the maximum force of static friction. Because the log is in equilibrium, we can apply the conditions for translational and rotational equilibrium to find the tension in the support wire and the angle the wire makes with the vertical wall.



Apply $\sum F_x = 0$ to the log:

$$T\sin\theta - f_{s,max} = 0$$

or

$$T\sin\theta = f_{s,max} = \mu_s F_n \qquad (1)$$

Apply $\sum F_y = 0$ to the log:

$$T\cos\theta + F_n - mg = 0$$

or

$$T\cos\theta = mg - F_n \qquad (2)$$

Divide equation (1) by equation (2) to obtain:

$$\frac{T\sin\theta}{T\cos\theta} = \frac{\mu_s F_n}{mg - F_n}$$

Solving for θ yields:

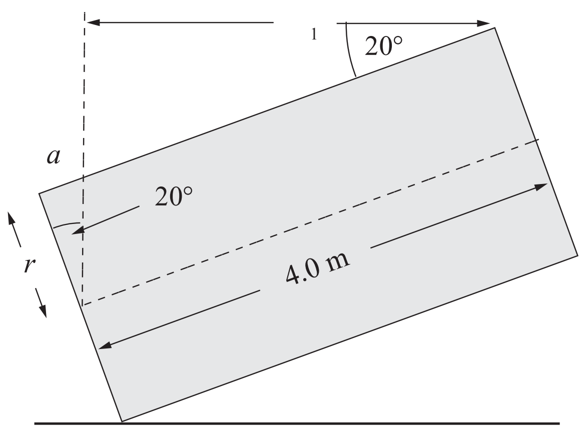
$$\theta = \tan^{-1}\left(\frac{\mu_s}{\frac{mg}{F_n} - 1}\right) \qquad (3)$$

Apply $\sum \vec{\tau} = 0$ about an axis through the origin: $\ell_2 mg - \ell_1 F_n - \ell_3 \mu_s F_n = 0$

Solve for F_n to obtain:

$$F_n = \frac{\ell_2 mg}{\ell_1 + \ell_3 \mu_s} \qquad (4)$$

Use the following diagram, in which the scale of the log has been modified to show important details, to show that $\ell_1 = 4.0\,\text{m} - a = [4.0\,\text{m} - r\tan 20°]\cos 20°$:



Substitute numerical values and evaluate ℓ_1:

$$\ell_1 = [4.0\,\text{m} - (0.12\,\text{m})\tan 20°]\cos 20° = 3.718\,\text{m}$$

Proceed similarly to show that ℓ_2 is given by:

$$\ell_2 = \left(4.0\,\text{m} - \tfrac{1}{2} r\tan 20°\right)\cos 20°$$

Substitute numerical values and evaluate ℓ_2:

$$\ell_2 = [2.0\,\text{m} - (0.06\,\text{m})\tan 20°]\cos 20° = 1.859\,\text{m}$$

Proceed as in the determination of the expression for ℓ_2 to show that ℓ_3 is given by:

$$\ell_3 = r\cos 20° + (4.0\,\text{m} - r\tan 20°)\sin 20°$$

Substitute numerical values and evaluate ℓ_3:

$$\ell_3 = (0.12\,\text{m})\cos 20° + [4.0\,\text{m} - (0.12\,\text{m})\tan 20°]\sin 20° = 1.466\,\text{m}$$

Substitute numerical values in equation (4) and evaluate F_n:

$$F_n = \frac{(1.859)(100\,\text{kg})(9.81\,\text{m/s}^2)}{3.718+(1.466)(0.60)} = 396.7\,\text{N}$$

Substitute numerical values in equation (3) and evaluate θ:

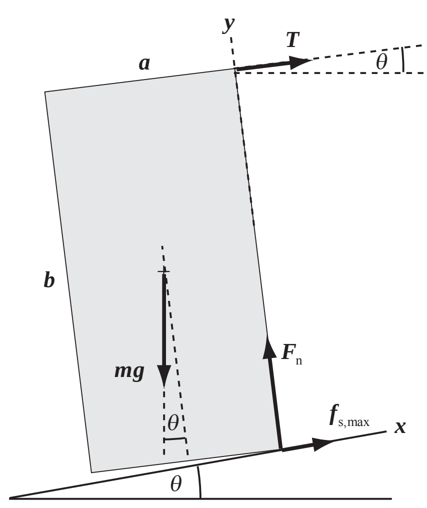
$$\theta = \tan^{-1}\left[\frac{0.60}{\frac{(100\,\text{kg})(9.81\,\text{m/s}^2)}{396.7\,\text{N}}-1}\right] = 22.16° = \boxed{22°}$$

Substitute numerical values in equation (1) and evaluate T:

$$T = \frac{(0.60)(396.7\,\text{N})}{\sin 22.16°} = \boxed{0.63\,\text{kN}}$$

39 ••• [SSM] A tall, uniform, rectangular block sits on an inclined plane as shown in Figure 12-45. A cord is attached to the top of the block to prevent it from falling down the incline. What is the maximum angle θ for which the block will not slide on the incline? Assume the block has a height-to-width ratio, b/a, of 4.0 and the coefficient of static friction between it and the incline is $\mu_s = 0.80$.

Picture the Problem Consider what happens just as θ increases beyond θ_{max}. Because the top of the block is fixed by the cord, the block will in fact rotate with only the lower right edge of the block remaining in contact with the plane. It follows that just prior to this slipping, F_n and $f_s = \mu_s F_n$ act at the lower right edge of the block. Choose a coordinate system in which up the incline is the $+x$ direction and the direction of $\vec{F}_n$ is the $+y$ direction. Because the block is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Apply $\sum F_x = 0$ to the block: $T + \mu_s F_n - mg\sin\theta = 0$ (1)

Apply $\sum F_y = 0$ to the block: $F_n - mg\cos\theta = 0$ (2)

Apply $\sum\vec{\tau} = 0$ about an axis through the lower right edge of the block: $\frac{1}{2}a(mg\cos\theta)+\frac{1}{2}b(mg\sin\theta)-bT=0$ (3)

Eliminate F_n between equations (1) and (2) and solve for T: $T = mg(\sin\theta - \mu_s\cos\theta)$

Substitute for T in equation (3):

$$\frac{1}{2}a(mg\cos\theta)+\frac{1}{2}b(mg\sin\theta) - b[mg(\sin\theta-\mu_s\cos\theta)]=0$$

Substitute $4a$ for b:

$$\frac{1}{2}a(mg\cos\theta)+\frac{1}{2}(4.0a)(mg\sin\theta) - (4.0a)[mg(\sin\theta-\mu_s\cos\theta)]=0$$

Simplify to obtain: $(1+8\mu_s)\cos\theta - 4\sin\theta = 0$

Solving for θ yields:

$$\theta = \tan^{-1}\left[\frac{1+8\mu_s}{4}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left[\frac{1+(8.0)(0.80)}{4.0}\right] = \boxed{62°}$$

Stress and Strain

40 • A 50-kg ball is suspended from a steel wire of length 5.0 m and radius 2.0 mm. By how much does the wire stretch?

Picture the Problem L is the unstretched length of the wire, F is the force acting on it, and A is its cross-sectional area. The stretch in the wire ΔL is related to Young's modulus by $Y = (F/A)/(\Delta L/L)$. We can use Table 12-1 to find the numerical value of Young's modulus for steel.

Find the amount the wire is stretched from Young's modulus:

$$Y = \frac{F/A}{\Delta L/L} \Rightarrow \Delta L = \frac{FL}{YA}$$

Substitute for F and A to obtain:

$$\Delta L = \frac{mgL}{Y\pi r^2}$$

Substitute numerical values and evaluate ΔL:

$$\Delta L = \frac{(50\,\text{kg})(9.81\,\text{m/s}^2)(5.0\,\text{m})}{(200\,\text{GN/m}^2)(\pi)(2.0\times10^{-3}\,\text{m})^2} = \boxed{0.98\,\text{mm}}$$

41 • **[SSM]** Copper has a tensile strength of about 3.0×10^8 N/m^2. (*a*) What is the maximum load that can be hung from a copper wire of diameter 0.42 mm? (*b*) If half this maximum load is hung from the copper wire, by what percentage of its length will it stretch?

Picture the Problem L is the unstretched length of the wire, F is the force acting on it, and A is its cross-sectional area. The stretch in the wire ΔL is related to Young's modulus by $Y = \text{stress/strain} = (F/A)/(\Delta L/L)$.

(*a*) Express the maximum load in terms of the wire's tensile strength:

$$F_{\text{max}} = \text{tensile strength} \times A = \text{tensile strength} \times \pi r^2$$

Substitute numerical values and evaluate F_{max}:

$$F_{\text{max}} = (3.0\times10^8\,\text{N/m}^2)\pi(0.21\times10^{-3}\,\text{m})^2 = 41.6\,\text{N} = \boxed{42\,\text{N}}$$

(*b*) Using the definition of Young's modulus, express the fractional change in length of the copper wire:

$$\frac{\Delta L}{L} = \frac{F}{AY} = \frac{\frac{1}{2}F_{\text{max}}}{AY}$$

Substitute numerical values and evaluate $\frac{\Delta L}{L}$:

$$\frac{\Delta L}{L} = \frac{\frac{1}{2}(41.6\,\text{N})}{\pi(0.21\,\text{mm})^2(1.10\times10^{11}\,\text{N/m}^2)} = \boxed{0.14\%}$$

42 • A 4.0-kg mass is supported by a steel wire of diameter 0.60 mm and length 1.2 m. How much will the wire stretch under this load?

Picture the Problem L is the unstretched length of the wire, F is the force acting on it, and A is its cross-sectional area. The stretch in the wire ΔL is related to Young's modulus by $Y = (F/A)/(\Delta L/L)$. We can use Table 12-1 to find the numerical value of Young's modulus for steel.

Relate the amount the wire is stretched to Young's modulus:

$$Y = \frac{F/A}{\Delta L/L} \Rightarrow \Delta L = \frac{FL}{YA}$$

Substitute for F and A to obtain:

$$\Delta L = \frac{mgL}{Y\pi r^2}$$

Substitute numerical values and evaluate ΔL:

$$\Delta L = \frac{(4.0\,\text{kg})(9.81\,\text{m/s}^2)(1.2\,\text{m})}{2\pi\times10^{11}\,\text{N/m}^2\,(0.30\times10^{-3}\,\text{m})^2} = \boxed{0.83\,\text{mm}}$$

43 • **[SSM]** As a runner's foot pushes off on the ground, the shearing force acting on an 8.0-mm-thick sole is shown in Figure 12-46. If the force of 25 N is distributed over an area of 15 cm^2, find the angle of shear θ, given that the shear modulus of the sole is 1.9×10^5 N/m^2.

Picture the Problem The shear stress, defined as the ratio of the shearing force to the area over which it is applied, is related to the shear strain through the definition of the shear modulus; $M_\text{s} = \dfrac{\text{shear stress}}{\text{shear strain}} = \dfrac{F_\text{s}/A}{\tan\theta}$.

Using the definition of shear modulus, relate the angle of shear, θ to the shear force and shear modulus:

$$\tan\theta = \frac{F_\text{s}}{M_\text{s}A} \Rightarrow \theta = \tan^{-1}\left(\frac{F_\text{s}}{M_\text{s}A}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left[\frac{25\,\text{N}}{(1.9\times10^5\,\text{N/m}^2)(15\times10^{-4}\,\text{m}^2)}\right] = \boxed{5.0^\circ}$$

44 •• A steel wire of length 1.50 m and diameter 1.00 mm is joined to an aluminum wire of identical dimensions to make a composite wire of length 3.00 m. Find the resulting change in the length of this composite wire if an object with a mass of 5.00 kg is hung vertically from one of its ends. (Neglect any effects the masses of the two wires have on the changes in their lengths.)

Picture the Problem The stretch in the wire ΔL is related to Young's modulus by $Y = (F/A)/(\Delta L/L)$, where L is the unstretched length of the wire, F is the force acting on it, and A is the cross-sectional area of the wire. The change in length of the composite wire is the sum of the changes in length of the steel and aluminum wires.

The change in length of the composite wire ΔL is the sum of the changes in length of the two wires:

$$\Delta L = \Delta L_\text{steel} + \Delta L_\text{Al}$$

Using the defining equation for Young's modulus, substitute for ΔL_{steel} and ΔL_{Al} in equation (1) and simplify to obtain:

$$\Delta L = \frac{F}{A}\frac{L_{\text{steel}}}{Y_{\text{steel}}} + \frac{F}{A}\frac{L_{\text{Al}}}{Y_{\text{Al}}} = \frac{F}{A}\left(\frac{L_{\text{steel}}}{Y_{\text{steel}}} + \frac{L_{\text{Al}}}{Y_{\text{Al}}}\right)$$

Substitute numerical values and evaluate ΔL:

$$\Delta L = \frac{(5.00\,\text{kg})(9.81\,\text{m/s}^2)}{\pi(0.500\times10^{-3}\,\text{m})^2}\left(\frac{1.50\,\text{m}}{2.00\times10^{11}\ \text{N/m}^2} + \frac{1.50\,\text{m}}{0.700\times10^{11}\ \text{N/m}^2}\right)$$
$$= 1.81\times10^{-3}\,\text{m} = \boxed{1.81\,\text{mm}}$$

45 •• [SSM] Equal but opposite forces of magnitude F are applied to both ends of a thin wire of length L and cross-sectional area A. Show that if the wire is modeled as a spring, the force constant k is given by $k = AY/L$ and the potential energy stored in the wire is $U = \frac{1}{2}F\Delta L$, where Y is Young's modulus and ΔL is the amount the wire has stretched.

Picture the Problem We can use Hooke's law and Young's modulus to show that, if the wire is considered to be a spring, the force constant k is given by $k = AY/L$. By treating the wire as a spring we can show the energy stored in the wire is $U = \frac{1}{2}F\Delta L$.

Express the relationship between the stretching force, the force constant, and the elongation of a spring:

$$F = k\Delta L \Rightarrow k = \frac{F}{\Delta L}$$

Using the definition of Young's modulus, express the ratio of the stretching force to the elongation of the wire:

$$\frac{F}{\Delta L} = \frac{AY}{L} \qquad (1)$$

Equate these two expressions for $F/\Delta L$ to obtain:

$$k = \boxed{\frac{AY}{L}}$$

Treating the wire as a spring, express its stored energy:

$$U = \tfrac{1}{2}k(\Delta L)^2 = \tfrac{1}{2}\frac{AY}{L}(\Delta L)^2 = \tfrac{1}{2}\left(\frac{AY\Delta L}{L}\right)\Delta L$$

Solving equation (1) for F yields:

$$F = \frac{AY\Delta L}{L}$$

Substitute for F in the expression for U to obtain:

$$U = \boxed{\tfrac{1}{2}F\Delta L}$$

46 •• The steel E string of a violin is under a tension of 53.0 N. The diameter of the string is 0.200 mm and the length under tension is 35.0 cm. Find (*a*) the unstretched length of this string and (*b*) the work needed to stretch the string.

Picture the Problem Let L' represent the stretched and L the unstretched length of the wire. The stretch in the wire ΔL is related to Young's modulus by $Y = (F/A)/(\Delta L/L)$, where F is the force acting on it, and A is its cross-sectional area. In Problem 45 we showed that the energy stored in the wire is $U = \frac{1}{2}F\Delta L$, where Y is Young's modulus and ΔL is the amount the wire has stretched.

(*a*) Express the stretched length L' of the wire:

$$L' = L + \Delta L$$

Using the definition of Young's modulus, express ΔL:

$$\Delta L = \frac{LF}{AY}$$

Substitute and simplify:

$$L' = L + \frac{LF}{AY} = L\left(1 + \frac{F}{AY}\right)$$

Solving for L yields:

$$L = \frac{L'}{1 + \dfrac{F}{AY}}$$

Substitute numerical values and evaluate L:

$$L = \frac{0.350\,\text{m}}{1 + \dfrac{53.0\,\text{N}}{\pi\left(0.100\times10^{-3}\,\text{m}\right)^2\left(2.00\times10^{11}\,\text{N/m}^2\right)}} = \boxed{34.7\,\text{cm}}$$

(*b*) From Problem 45, the work done in stretching the wire is:

$$W = \Delta U = \tfrac{1}{2}F\Delta L$$

Substitute numerical values and evaluate W:

$$W = \tfrac{1}{2}(53.0\,\text{N})(0.350\,\text{m} - 0.347\,\text{m}) \approx \boxed{0.08\,\text{J}}$$

47 •• During a materials science experiment on the Young's modulus of rubber, your teaching assistant supplies you and your team with a rubber strip that is rectangular in cross section. She tells you to first measure the cross section dimensions and their values are 3.0 mm × 1.5 mm. The lab write-up calls for the rubber strip to be suspended vertically and various (known) masses attached to it. Your team obtains the following data for the length of the strip as a function of the load (mass) on the end of the strip:

Load, kg	0.0	0.10	0.20	0.30	0.40	0.50
Length, cm	5.0	5.6	6.2	6.9	7.8	8.8

(*a*) Use a **spreadsheet** or **graphing calculator** to find Young's modulus for the rubber strip over this range of loads. *Hint: It is probably best to plot F/A versus ΔL/L. Why?*
(*b*) Find the energy stored in the strip when the load is 0.15 kg. (See Problem 45.)
(*c*) Find the energy stored in the strip when the load is 0.30 kg. Is it twice as much as your answer to Part (*b*)? Explain.

Picture the Problem We can use the definition of Young's modulus and your team's data to plot a graph whose slope is Young's modulus for the rubber strip over the given range of loads. Because the rubber strip stretches linearly for loads less than or equal to 0.20 kg, we can use linear interpolation in Part (*b*) to find the length of the rubber strip for a load of 0.15 kg. We can then use the result of Problem 45 to find the energy stored in the when the load is 0.15 kg. In Part (*c*) we can use the result of Problem 45 and the given length of the strip when its load is 0.30 kg to find the energy stored in the rubber strip.

(*a*) The equation for Young's modulus can be written as:

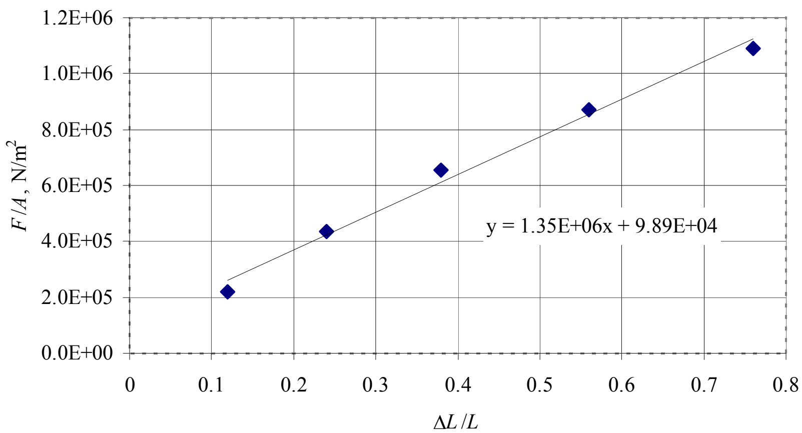
$$\frac{F}{A}=Y\frac{\Delta L}{L}$$

where Y is the slope of a graph of F/A as a function of $\Delta L/L$.

The following table summarizes the quantities, calculated using your team's data, used to plot the graph suggested in the problem statement.

Load	F	F/A	ΔL	$\Delta L/L$	U
(kg)	(N)	(N/m^2)	(m)		(J)
0.10	0.981	21.8×10^5	0.006	0.12	2.9×10^{-3}
0.20	1.962	4.36×10^5	0.012	0.24	12×10^{-3}
0.30	2.943	6.54×10^5	0.019	0.38	28×10^{-3}
0.40	3.924	8.72×10^5	0.028	0.56	55×10^{-3}
0.50	4.905	10.9×10^5	0.038	0.76	93×10^{-3}

A spreadsheet-generated graph of F/A as a function of $\Delta L/L$ follows. The spreadsheet program also plotted the regression line on the graph and added its equation to the graph.



From the regression function shown on the graph:

$$Y = \boxed{1.4\times10^{6}\ \text{N/m}^2}$$

(*b*) From Problem 45:

$$U = \tfrac{1}{2}\Delta LF$$

or, because $F = mg$,

$$U(m) = \tfrac{1}{2}\Delta Lmg$$

Interpolating from the data table we see that the length of the strip when the load on it is 0.15 kg is 5.9 cm. Substitute numerical values and evaluate U(0.15 kg):

$$U(0.15\ \text{kg}) = \tfrac{1}{2}(5.9\ \text{cm} - 5.0\ \text{cm})(0.15\ \text{kg})(9.81\ \text{m/s}^2) = \boxed{7\ \text{mJ}}$$

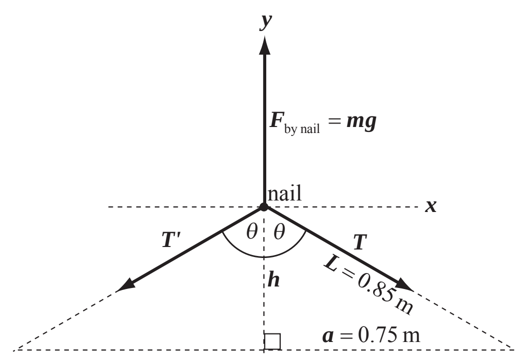
(*c*) Evaluate U(0.30 kg) to obtain:

$$U(0.30\ \text{kg}) = \tfrac{1}{2}(6.9\ \text{cm} - 5.0\ \text{cm})(0.30\ \text{kg})(9.81\ \text{m/s}^2) = \boxed{28\ \text{mJ}}$$

The energy stored in the strip when the load is 0.30 kg is four times as much as the energy stored when the load is 0.15 kg. Although the rubber strip does not stretch linearly (a conclusion you can confirm either graphically or by examining the data table), its stretch is sufficiently linear that, to a good approximation, the energy stored is quadrupled when the load is doubled.

48 •• A large mirror is hung from a nail as shown in Figure 12-47. The supporting steel wire has a diameter of 0.20 mm and an unstretched length of 1.7 m. The distance between the points of support at the top of the mirror's frame is 1.5 m. The mass of the mirror is 2.4 kg. How much will the distance between the nail and the mirror increase due to the stretching of the wire as the mirror is hung?

Picture the Problem The figure shows the forces acting on the wire where it passes over the nail. *m* represents the mass of the mirror and *T* is the tension in the supporting wires. The figure also shows the geometry of the right triangle defined by the support wires and the top of the mirror frame. The distance *a* is fixed by the geometry while *h* and *L* will change as the mirror is suspended from the nail.



Using the Pythagorean theorem, express the relationship between the sides of the right triangle in the diagram:

$$a^2 + h^2 = L^2$$

Express the differential of this equation and approximate differential changes with small changes:

$$2a\Delta a + 2h\Delta h = 2L\Delta L$$

or, because $\Delta a = 0$,

$$h\Delta h = L\Delta L \Rightarrow \Delta h = \frac{L\Delta L}{h}$$

Multiplying the numerator and denominator by L yields:

$$\Delta h = \frac{L^2}{h}\frac{\Delta L}{L} \qquad (1)$$

Solve the equation defining Young's modulus for $\Delta L/L$ to obtain:

$$\frac{\Delta L}{L} = \frac{T}{AY}$$

Substitute for $\Delta L/L$ in equation (1) to obtain:

$$\Delta h = \frac{L^2}{h}\frac{T}{AY} = \frac{L^2}{\sqrt{L^2 - a^2}}\frac{T}{\pi r^2 Y} \qquad (2)$$

where r is the radius of the wire.

Noting that $T = T'$, apply $\sum F_y = 0$ to the wire where it passes over the supporting nail:

$$mg - 2T\cos\theta = 0 \Rightarrow T = \frac{mg}{2\cos\theta}$$

Substituting for T in equation (2) yields:

$$\Delta h = \frac{L^2}{\sqrt{L^2 - a^2}} \frac{mg}{2\pi r^2 Y \cos\theta}$$

Because $\cos\theta = \dfrac{h}{L} = \dfrac{\sqrt{L^2 - a^2}}{L}$:

$$\Delta h = \frac{L^2}{\sqrt{L^2 - a^2}} \frac{mgL}{2\pi r^2 Y \sqrt{L^2 - a^2}} = \frac{mgL^3}{2\pi r^2 Y \left(L^2 - a^2\right)}$$

Substitute numerical values and evaluate Δh:

$$\Delta h = \frac{(2.4\ \text{kg})\left(9.81\ \text{m/s}^2\right)(0.85\ \text{m})^3}{2\pi\left(0.10\times10^{-3}\ \text{m}\right)^2\left(2.00\times10^{11}\ \text{N/m}^2\right)\left[(0.85\ \text{m})^2 - (0.75\ \text{m})^2\right]} = \boxed{7.2\ \text{mm}}$$

49 •• Two masses, M_1 and M_2, are supported by wires that have equal lengths when unstretched. The wire supporting M_1 is an aluminum wire 0.70 mm in diameter, and the one supporting M_2 is a steel wire 0.50 mm in diameter. What is the ratio M_1/M_2 if the two wires stretch by the same amount?

Picture the Problem Let the numeral 1 denote the aluminum wire and the numeral 2 the steel wire. Because their initial lengths and amount they stretch are the same, we can use the definition of Young's modulus to express the change in the lengths of each wire and then equate these expressions to obtain an equation solvable for the ratio M_1/M_2.

Using the definition of Young's modulus, express the change in length of the aluminum wire:

$$\Delta L_1 = \frac{M_1 g L_1}{A_1 Y_{\text{Al}}}$$

Using the definition of Young's modulus, express the change in length of the steel wire:

$$\Delta L_2 = \frac{M_2 g L_2}{A_2 Y_{\text{steel}}}$$

Because the two wires stretch by the same amount, equate ΔL_1 and ΔL_2 and simplify:

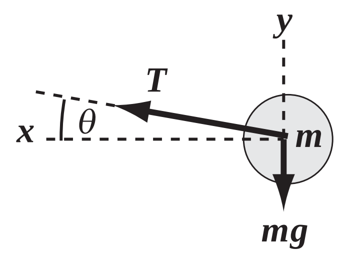
$$\frac{M_1}{A_1 Y_{\text{Al}}} = \frac{M_2}{A_2 Y_{\text{steel}}} \Rightarrow \frac{M_1}{M_2} = \frac{A_1 Y_{\text{Al}}}{A_2 Y_{\text{steel}}}$$

Substitute numerical values and evaluate M_1/M_2:

$$\frac{M_1}{M_2}=\frac{\frac{\pi}{4}(0.70\,\text{mm})^2\left(0.70\times10^{11}\ \text{N/m}^2\right)}{\frac{\pi}{4}(0.50\,\text{mm})^2\left(2.00\times10^{11}\ \text{N/m}^2\right)}=\boxed{0.69}$$

50 •• A 0.50-kg ball is attached to one end of an aluminum wire having a diameter of 1.6 mm and an unstretched length of 0.70 m. The other end of the wire is fixed to the top of a post. The ball rotates about the post in a horizontal plane at a rotational speed such that the angle between the wire and the horizontal is 5.0º. Find the tension in the wire and the increase in its length due to the tension in the wire.

Picture the Problem The free-body diagram shows the forces acting on the ball as it rotates around the post in a horizontal plane. We can apply Newton's second law to find the tension in the wire and use the definition of Young's modulus to find the amount by which the aluminum wire stretches.



Apply $\sum F_y=0$ to the ball:

$$T\sin\theta-mg=0\Rightarrow T=\frac{mg}{\sin\theta}$$

Substitute numerical values and evaluate T:

$$T=\frac{(0.50\,\text{kg})\left(9.81\,\text{m/s}^2\right)}{\sin5.0°}=56.3\ \text{N}=\boxed{56\,\text{N}}$$

Using the definition of Young's modulus, express ΔL:

$$\Delta L=\frac{FL}{AY}$$

Substitute numerical values and evaluate ΔL:

$$\Delta L=\frac{(56.3\,\text{N})(0.70\,\text{m})}{\frac{\pi}{4}\left(1.6\times10^{-3}\ \text{m}\right)^2\left(0.70\times10^{11}\ \text{N/m}^2\right)}=\boxed{0.28\,\text{mm}}$$

51 •• [SSM] An elevator cable is to be made of a new type of composite developed by Acme Laboratories. In the lab, a sample of the cable that is 2.00 m long and has a cross-sectional area of 0.200 mm^2 fails under a load of 1000 N. The actual cable used to support the elevator will be 20.0 m long and have a cross-sectional area of 1.20 mm^2. It will need to support a load of 20,000 N safely. Will it?

Picture the Problem We can use the definition of stress to calculate the failing stress of the cable and the stress on the elevator cable. Note that the failing stress of the composite cable is the same as the failing stress of the test sample.

The stress on the elevator cable is:

$$\text{Stress}_{\text{cable}} = \frac{F}{A} = \frac{20.0\,\text{kN}}{1.20\times10^{-6}\,\text{m}^2} = 1.67\times10^{10}\ \text{N/m}^2$$

The failing stress of the sample is:

$$\text{Stress}_{\text{failing}} = \frac{F}{A} = \frac{1000\,\text{N}}{0.2\times10^{-6}\,\text{m}^2} = 0.500\times10^{10}\ \text{N/m}^2$$

Because $\text{Stress}_{\text{failing}} < \text{Stress}_{\text{cable}}$, the cable will not support the elevator.

52 •• If a material's density remains constant when it is stretched in one direction, then (because its total volume remains constant), its length must decrease in one or both of the other directions. Take a rectangular block of length *x*, width *y*, and depth z, and pull on it so that its new length $x' = x + \Delta x$. If $\Delta x << x$ and $\Delta y/y = \Delta z/z$, show that $\Delta y/y = -\frac{1}{2}\Delta x/x$.

Picture the Problem Let the length of the sides of the rectangle be *x*, *y* and *z*. Then the volume of the rectangle will be $V = xyz$ and we can express the new volume V' resulting from the pulling in the *x* direction and the change in volume ΔV in terms of Δx, Δy, and Δz. Discarding the higher order terms in ΔV and dividing our equation by V and using the given condition that $\Delta y/y = \Delta z/z$ will lead us to the given expression for $\Delta y/y$.

Express the new volume of the rectangular box when its sides change in length by Δx, Δy, and Δz:

$$V' = (x+\Delta x)(y+\Delta y)(z+\Delta z) = xyz + \Delta x(yz) + \Delta y(xz) + \Delta z(xy) + \{z\Delta x\Delta y + y\Delta x\Delta z + x\Delta y\Delta z + \Delta x\Delta y\Delta z\}$$

where the terms in brackets are very small (i.e., second order or higher).

Discard the second order and higher terms to obtain:

$$V' = V + \Delta x(yz) + \Delta y(xz) + \Delta z(xy)$$

or

$$\Delta V = V' - V = \Delta x(yz) + \Delta y(xz) + \Delta z(xy)$$

Because $\Delta V = 0$:

$$\Delta x(yz) = -[\Delta y(xz) + \Delta z(xy)]$$

Divide both sides of this equation by $V = xyz$ to obtain:

$$\frac{\Delta x}{x} = -\left[\frac{\Delta y}{y} + \frac{\Delta z}{z}\right]$$

Because $\Delta y/y = \Delta z/z$, our equation becomes:

$$\frac{\Delta x}{x} = -2\frac{\Delta y}{y} \Rightarrow \frac{\Delta y}{y} = \boxed{-\frac{1}{2}\frac{\Delta x}{x}}$$

53 •• **[SSM]** You are given a wire with a circular cross-section of radius r and a length L. If the wire is made from a material whose density remains constant when it is stretched in one direction, then show that $\Delta r/r = -\frac{1}{2}\Delta L/L$, assuming that $\Delta L << L$. (See Problem 52.)

Picture the Problem We can evaluate the differential of the volume of the wire and, using the assumptions that the volume of the wire does not change under stretching and that the change in its length is small compared to its length, show that $\Delta r/r = -\frac{1}{2}\Delta L/L\,L$.

The volume of the wire is given by:

$$V = \pi r^2 L$$

Evaluate the differential of V to obtain:

$$dV = \pi r^2 dL + 2\pi rLdr$$

Because $dV = 0$:

$$0 = rdL + 2Ldr \Rightarrow \frac{dr}{r} = -\frac{1}{2}\frac{dL}{L}$$

Because $\Delta L << L$, we can approximate the differential changes dr and dL with small changes Δr and ΔL to obtain:

$$\frac{\Delta r}{r} = \boxed{-\frac{1}{2}\frac{\Delta L}{L}}$$

54 ••• For most materials listed in Table 12-1, the tensile strength is two to three orders of magnitude lower than Young's modulus. Consequently, most of these materials will break before their strain exceeds 1 percent. Of man-made materials, nylon has about the greatest extensibility—it can take strains of about 0.2 before breaking. But spider silk beats anything man-made. Certain forms of spider silk can take strains on the order of 10 before breaking! (*a*) If such a thread has a circular cross-section of radius r_0 and unstretched length L_0, find its new radius r when stretched to a length $L = 10L_0$. (Assume that the density of the thread remains

constant as it stretches.) (*b*) If the Young's modulus of the spider thread is Y, calculate the tension needed to break the thread in terms of Y and r_0.

Picture the Problem Because the density of the thread remains constant during the stretching process, we can equate the initial and final volumes to express r_0 in terms of r. We can also use Young's modulus to express the tension needed to break the thread in terms of Y and r_0.

(*a*) Because the volume of the thread is constant during the stretching of the spider's silk:

$$\pi r^2 L = \pi r_0^2 L_0 \Rightarrow r = r_0\sqrt{\frac{L_0}{L}}$$

Substitute for L and simplify to obtain:

$$r = r_0\sqrt{\frac{L_0}{10L_0}} = \boxed{0.316r_0}$$

(*b*) Express Young's modulus in terms of the breaking tension T:

$$Y = \frac{T/A}{\Delta L/L} = \frac{T/\pi r^2}{\Delta L/L} = \frac{10T/\pi r_0^2}{\Delta L/L}$$

Solving for T yields:

$$T = \frac{1}{10}\pi r_0^2 Y\frac{\Delta L}{L}$$

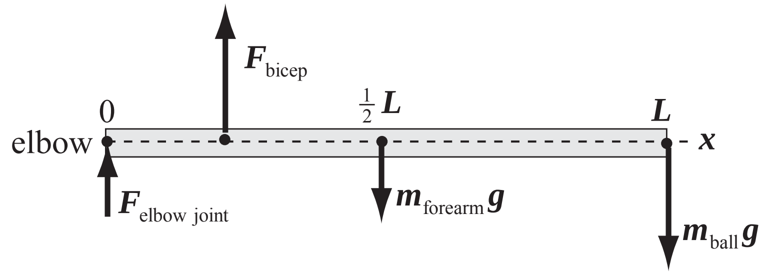
Because $\Delta L/L = 9$:

$$T = \boxed{\frac{9\pi r_0^2 Y}{10}}$$

General Problems

55 • [SSM] A standard bowling ball weighs 16 pounds. You wish to hold a bowling ball in front of you, with the elbow bent at a right angle. Assume that your biceps attaches to your forearm at 2.5 cm out from the elbow joint, and that your biceps muscle pulls vertically upward, that is, it acts at right angles to the forearm. Also assume that the ball is held 38 cm out from the elbow joint. Let the mass of your forearm be 5.0 kg and assume its center of gravity is located 19 cm out from the elbow joint. How much force must your biceps muscle apply to forearm in order to hold out the bowling ball at the desired angle?

Picture the Problem We can model the forearm as a cylinder of length L = 38 cm with the forces shown in the pictorial representation acting on it. Because the forearm is in both translational and rotational equilibrium under the influence of these forces, the forces in the diagram must add (vectorially) to zero and the net torque with respect to any axis must also be zero.



Apply $\sum \vec{\tau} = 0$ about an axis through the elbow and perpendicular to the plane of the diagram:

$$\ell F_{\text{bicep}} - \tfrac{1}{2} L m_{\text{forearm}} g - L m_{\text{ball}} g = 0$$

Solving for F_{bicep} and simplifying yields:

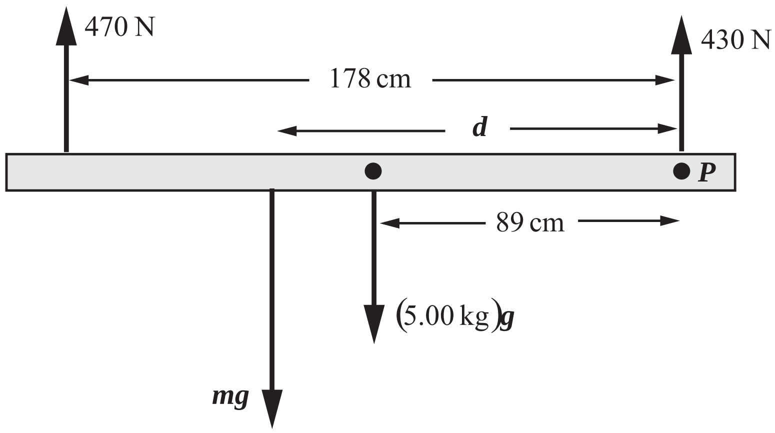
$$F_{\text{bicep}} = \frac{\tfrac{1}{2} L m_{\text{forearm}} g + L m_{\text{ball}} g}{\ell} = \frac{\left(\tfrac{1}{2} m_{\text{forearm}} + m_{\text{ball}}\right) L g}{\ell}$$

Substitute numerical values and evaluate F_{bicep}:

$$F_{\text{bicep}} = \frac{\left(\tfrac{1}{2}(5.0\,\text{kg}) + 16\,\text{lb} \times \dfrac{1\,\text{kg}}{2.205\,\text{lb}}\right)(38\,\text{cm})\left(9.81\,\text{m/s}^2\right)}{2.5\,\text{cm}} = \boxed{1.5\,\text{kN}}$$

56 •• A biology laboratory at your university is studying the location of a person's center of gravity as a function of their body weight. They pay well, and you decide to volunteer. The location of your center of gravity when standing erect is to be determined by having you lie on a uniform board (mass of 5.00 kg, length 2.00 m) supported by two scales as shown in Figure 12-48. If your height is 188 cm and the left scale reads 470 N while the right scale reads 430 N, where is your center of gravity relative to your feet? Assume the scales are both exactly the same distance from the two ends of the board, are separated by 178 cm, and are set to each read zero before you get on the platform.

Picture the Problem Because the you-board system is in equilibrium, we can apply the conditions for translational and rotational equilibrium to relate the forces exerted by the scales to the distance *d*, measured from your feet, to your center of mass and the distance to the center of gravity of the board. The following pictorial representation shows the forces acting on the board. mg represents your weight.



The forces responsible for a counterclockwise torque about an axis through your feet (point *P*) and perpendicular to the page are your weight and the weight of the board. The only force causing a clockwise torque about this axis is the 470 N force exerted by the scale under your head. Apply $\sum\vec{\tau}=0$ about an axis through your feet and perpendicular to the page:

$$m\left(9.81\,\text{m/s}^2\right)d-(5.0\,\text{kg})(0.89\,\text{m})-(1.78\,\text{m})(470\,\text{N})=0$$

where *m* is your mass.

Solve for *d* to obtain:

$$d=\frac{(5.00\,\text{kg})(0.89\,\text{m})+(1.78\,\text{m})(470\,\text{N})}{m\left(9.81\,\text{m/s}^2\right)} \qquad (1)$$

Let upward be the positive *y* direction and apply $\sum F_y=0$ to the plank to obtain:

$$470\,\text{N}+430\,\text{N}-m\left(9.81\,\text{m/s}^2\right)-(5.00\,\text{kg})\left(9.81\,\text{m/s}^2\right)=0$$

Solving for *m* yields: $m=86.74\,\text{kg}$

Substitute numerical values in equation (1) and evaluate *d*:

$$d=\frac{(5.0\,\text{kg})(0.89\,\text{m})+(1.78\,\text{m})(470\,\text{N})}{(86.74\,\text{kg})\left(9.81\,\text{m/s}^2\right)}=\boxed{99\,\text{cm}}$$

57 •• Figure 12-49 shows a mobile consisting of four objects hanging on three rods of negligible mass. Find the values of the unknown masses of the objects if the mobile is to balance. *Hint: Find the mass* m_1 *first*.

Picture the Problem We can apply the balance condition $\sum\vec{\tau}=0$ successively, starting with the lowest part of the mobile, to find the value of each of the unknown weights.

Apply $\sum\vec{\tau}=0$ about an axis through the point of suspension of the lowest part of the mobile:

$$(3.0\,\text{cm})(2.0\,\text{N})-(4.0\,\text{cm})m_1g=0$$

Solving for m_1 yields:

$$m_1=0.1529\,\text{kg}=\boxed{0.15\,\text{kg}}$$

Apply $\sum\vec{\tau}=0$ about an axis through the point of suspension of the middle part of the mobile:

$$(2.0\,\text{cm})m_2g-(4.0\,\text{cm})\left(\frac{2.0\,\text{N}}{g}+0.1529\,\text{kg}\right)g=0$$

Solving for m_2 yields:

$$m_2=0.7136\,\text{kg}=\boxed{0.71\,\text{kg}}$$

Apply $\sum\vec{\tau}=0$ about an axis through the point of suspension of the top part of the mobile:

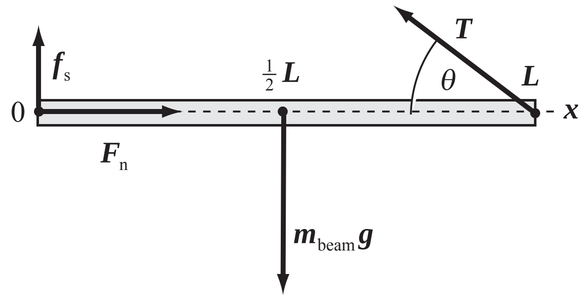
$$(2.0\,\text{cm})(2.0\,\text{N}+(0.7136\,\text{kg})g+(0.1529)g)-(6.0\,\text{cm})m_3g=0$$

Solving for m_3 yields:

$$m_3=0.3568\,\text{kg}=\boxed{0.36\,\text{kg}}$$

58 •• Steel construction beams, with an industry designation of ″W12 × 22,″ have a weight of 22 pounds per foot. A new business in town has hired you to place its sign on a 4.0 m long steel beam of this type. The design calls for the beam to extend outward horizontally from the front brick wall (Figure 12-50). It is to be held in place by a 5.0 m-long steel cable. The cable is attached to one end of the beam and to the wall above the point at which the beam is in contact with the wall. During the initial stage of construction, the beam is *not* to be bolted to the wall, but to be held in place solely by friction. (*a*) What is the minimum coefficient of friction between the beam and the wall for the beam to remain in static equilibrium? (*b*)What is the tension in the cable in this case?

Picture the Problem Because the beam is in both translational and rotational equilibrium under the influence of the forces shown below in the pictorial representation, we can apply $\sum\vec{F}=0$ and $\sum\vec{\tau}=0$ to it to find the coefficient of static friction and the tension in the supporting cable.



(*a*) Apply $\sum\vec{F}=0$ to the beam to obtain:

$$\sum F_x = F_n - T\cos\theta = 0 \quad (1)$$

and

$$\sum F_y = f_s - m_{beam}g + T\sin\theta = 0 \quad (2)$$

The mass of the beam m_{beam} is the product of its linear density λ and length L:

$$m_{beam} = \lambda L$$

Substituting for m_{beam} in equation (2) yields:

$$f_s - \lambda Lg + T\sin\theta = 0 \quad (3)$$

Relate the force of static friction to the normal force exerted by the wall:

$$f_s = \mu_s F_n$$

Substituting for f_s in equation (3) yields:

$$\mu_s F_n - \lambda Lg + T\sin\theta = 0$$

Solve for μ_s to obtain:

$$\mu_s = \frac{\lambda Lg - T\sin\theta}{F_n} \quad (4)$$

Solving equation (1) for F_n yields:

$$F_n = T\cos\theta$$

Substitute for F_n in equation (4) and simplify to obtain:

$$\mu_s = \frac{\lambda Lg - T\sin\theta}{T\cos\theta} = \frac{\lambda Lg}{T\cos\theta} - \tan\theta \quad (5)$$

Apply $\sum\vec{\tau}=0$ to the beam about an axis through the origin and normal to the page to obtain:

$$(T\sin\theta)L - m_{beam}g\left(\tfrac{1}{2}L\right) = 0$$

or

$$(T\sin\theta)L - \lambda Lg\left(\tfrac{1}{2}L\right) = 0$$

Solving for T yields:

$$T = \frac{\lambda L g}{2\sin\theta} \qquad (6)$$

Substitute for T in equation (5) and simplify to obtain:

$$\mu_s = \frac{\lambda L g}{\dfrac{\lambda L g}{2\sin\theta}\cos\theta} - \tan\theta = \tan\theta \qquad (7)$$

From Figure 12-50 we see that:

$$\tan\theta = \frac{3.0\ \text{m}}{4.0\ \text{m}} = \frac{3}{4}$$

Substituting for $\tan\theta$ in equation (7) yields:

$$\mu_s = \boxed{0.75}$$

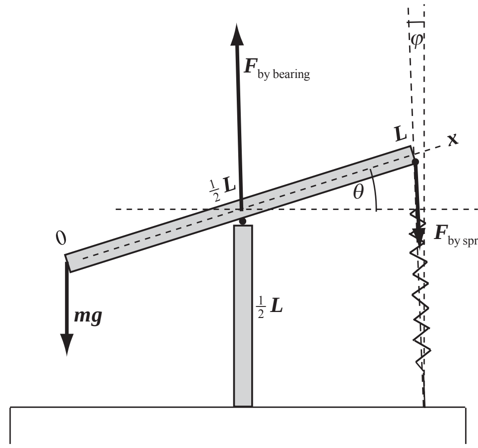
(b) Substitute numerical values in equation (6) and evaluate T:

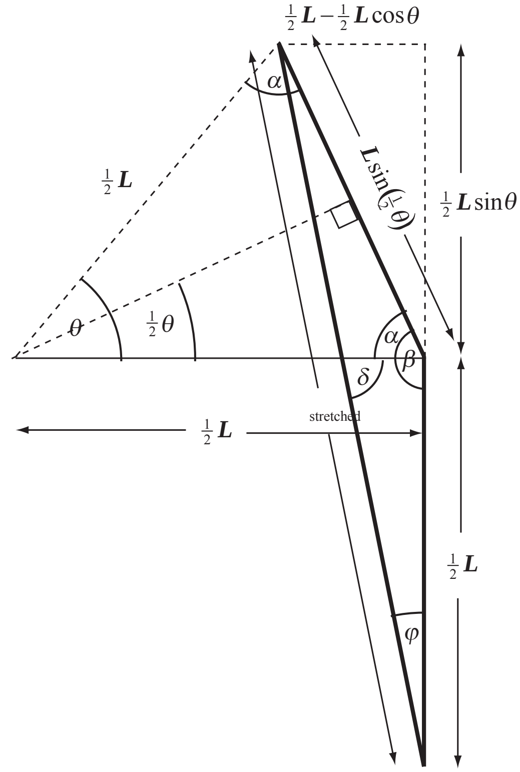
$$T = \frac{\left(22\,\dfrac{\text{lb}}{\text{ft}} \times \dfrac{1\ \text{kg}}{2.205\ \text{lb}} \times \dfrac{3.281\ \text{ft}}{\text{m}}\right)(4.0\ \text{m})\left(9.81\ \text{m/s}^2\right)}{2\sin\left(\tan^{-1}\left(\dfrac{3}{4}\right)\right)} = \boxed{1.1\ \text{kN}}$$

Remarks: 1.1 kN is approximately 240 lb.

59 ••• [SSM] Consider a rigid 2.5-m-long beam (Figure 12-51) that is supported by a fixed 1.25-m-high post through its center and pivots on a frictionless bearing at its center atop the vertical 1.25-m-high post. One end of the beam is connected to the floor by a spring that has a force constant k = 1250 N/m. When the beam is horizontal, the spring is vertical and unstressed. If an object is hung from the opposite end of the beam, the beam settles into an equilibrium position where it makes an angle of 17.5° with the horizontal. What is the mass of the object?

Picture the Problem Because the beam is in rotational equilibrium, we can apply $\sum\vec{\tau} = 0$ to it to determine the mass of the object suspended from its left end.





The pictorial representation directly above shows the forces acting on the beam when it is in static equilibrium. The pictorial representation to the right is an enlarged view of the right end of the beam. We'll use this diagram to determine the length of the stretched spring.

Apply $\sum\vec{\tau}=0$ to the beam about an axis through the bearing point to obtain:

$$mg\left(\tfrac{1}{2}L\cos\theta\right)-F_{\text{by spring}}\left(\tfrac{1}{2}L\sin\varphi\right)=0$$

or, because $F_{\text{by spring}}=k\Delta\ell_{\text{spring}}$,

$$mg\cos\theta-k\Delta\ell_{\text{spring}}\sin\varphi=0 \qquad (1)$$

Use the right-hand diagram above to relate the angles φ and θ:

$$\varphi=\tan^{-1}\left(\frac{\frac{1}{2}L-\frac{1}{2}L\cos\theta}{\frac{1}{2}L+\frac{1}{2}L\sin\theta}\right)=\tan^{-1}\left(\frac{1-\cos\theta}{1+\sin\theta}\right)$$

Substitute for φ in equation (1) to obtain:

$$mg\cos\theta-k\Delta\ell_{\text{spring}}\sin\left(\tan^{-1}\left(\frac{1-\cos\theta}{1+\sin\theta}\right)\right)=0$$

Solve for m to obtain:

$$m=\frac{k\Delta\ell_{\text{spring}}\sin\left(\tan^{-1}\left(\frac{1-\cos\theta}{1+\sin\theta}\right)\right)}{g\cos\theta} \qquad (2)$$

$\Delta\ell_{\text{spring}}$ is given by:

$$\Delta\ell_{\text{spring}} = \ell_{\text{stretched}} - \ell_{\text{unstretched}}$$

or, because $\ell_{\text{unstretched}} = \frac{1}{2}L$,

$$\Delta\ell_{\text{spring}} = \ell_{\text{stretched}} - \tfrac{1}{2}L \qquad (3)$$

To find the value of $\ell_{\text{stretched}}$, refer to the right-hand diagram and note that:

$$2\alpha + \theta = \pi \Rightarrow \alpha = \frac{\pi}{2} - \frac{1}{2}\theta$$

Again, referring to the diagram, relate β to α:

$$\beta = \alpha + \frac{\pi}{2}$$

Substituting for α yields:

$$\beta = \frac{\pi}{2} - \frac{1}{2}\theta + \frac{\pi}{2} = \pi - \frac{1}{2}\theta$$

Apply the law of cosines to the triangle defined with bold sides:

$$\ell^2_{\text{stretched}} = \left(\tfrac{1}{2}L\right)^2 + \left(L\sin\tfrac{1}{2}\theta\right)^2 - 2\left(\tfrac{1}{2}L\right)\left(L\sin\tfrac{1}{2}\theta\right)\cos\left(\pi - \tfrac{1}{2}\theta\right)$$

Use the formula for the cosine of the difference of two angles to obtain:

$$\cos\left(\pi - \tfrac{1}{2}\theta\right) = -\cos\tfrac{1}{2}\theta$$

Substituting for $\cos\left(\pi - \tfrac{1}{2}\theta\right)$ yields:

$$\begin{aligned}\ell^2_{\text{stretched}} &= \left(\tfrac{1}{2}L\right)^2 + \left(L\sin\tfrac{1}{2}\theta\right)^2 + 2\left(\tfrac{1}{2}L\right)\left(L\sin\tfrac{1}{2}\theta\right)\cos\tfrac{1}{2}\theta \\ &= \tfrac{1}{4}L^2 + L^2\sin^2\tfrac{1}{2}\theta + \tfrac{1}{2}L^2\left(2\sin\tfrac{1}{2}\theta\cos\tfrac{1}{2}\theta\right)\end{aligned}$$

Use the trigonometric identities $\sin\theta = 2\sin\frac{1}{2}\theta\cos\frac{1}{2}\theta$ and $\sin^2\frac{1}{2}\theta = \dfrac{1-\cos\theta}{2}$ to obtain:

$$\ell^2_{\text{stretched}} = \tfrac{1}{4}L^2 + L^2\left(\frac{1-\cos\theta}{2}\right) + \tfrac{1}{2}L^2(\sin\theta)$$

Simplifying yields:

$$\ell^2_{\text{stretched}} = \tfrac{1}{4}L^2\left[3 - 2(\cos\theta - \sin\theta)\right]$$

or

$$\ell_{\text{stretched}} = \tfrac{1}{2}L\sqrt{3 - 2(\cos\theta - \sin\theta)}$$

Substituting for $\ell_{\text{stretched}}$ in equation (3) yields:

$$\Delta\ell_{\text{spring}} = \tfrac{1}{2}L\sqrt{3-2(\cos\theta-\sin\theta)} - \tfrac{1}{2}L = \tfrac{1}{2}L\left(\sqrt{3-2(\cos\theta-\sin\theta)}-1\right)$$

Substitute for $\Delta\ell_{\text{spring}}$ in equation (2) to obtain:

$$m = \frac{\tfrac{1}{2}kL\left(\sqrt{3-2(\cos\theta-\sin\theta)}-1\right)\sin\left(\tan^{-1}\left(\frac{1-\cos\theta}{1+\sin\theta}\right)\right)}{g\cos\theta}$$

Substitute numerical values and evaluate m:

$$m = \frac{\tfrac{1}{2}(1250\text{ N/m})(2.5\text{ m})\left(\sqrt{3-2(\cos17.5°-\sin17.5°)}-1\right)\sin\left(\tan^{-1}\left(\frac{1-\cos17.5°}{1+\sin17.5°}\right)\right)}{(9.81\text{ m/s}^2)\cos17.5°}$$

$$= \boxed{1.8\text{ kg}}$$

60 •• A rope and pulley system, called a *block and tackle*, is used to raise an object of mass *M* (Figure 12-52) at constant speed. When the end of the rope moves downward through a distance *L,* the height of the lower pulley is increased by *h*. (*a*) What is the ratio *L*/*h*? (*b*) Assume that the mass of the block and tackle is negligible and that the pulley bearings are frictionless. Show that *FL* = *mgh* by applying the work–energy principle to the block–tackle object.

Picture the Problem We can determine the ratio of *L* to *h* by noting the number of ropes supporting the load whose mass is *M*.

(*a*) Noting that three ropes support the pulley to which the object whose mass is *M* is fastened we can conclude that:

$$\frac{L}{h} = \boxed{3}$$

(*b*) Apply the work-energy principle to the block-tackle object to obtain:

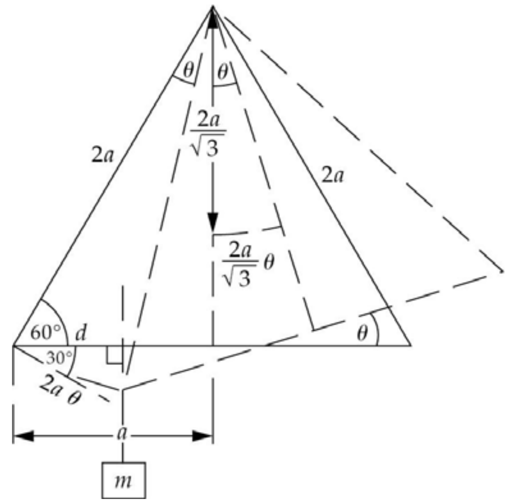
$$W_{\text{ext}} = \Delta E_{\text{system}} = \Delta U_{\text{block-tackle}}$$

or

$$FL = \boxed{mgh}$$

61 •• A plate of mass *M* in the shape of an equilateral triangle is suspended from one corner and a mass *m* is suspended from another of its corners. If the base of the triangle makes an angle of 6.0º with the horizontal, what is the ratio *m*/*M*?

Picture the Problem The figure shows the equilateral triangle without the mass m, and then the same triangle with the mass m and rotated through an angle θ. Let the side length of the triangle to be $2a$. Then the center of mass of the triangle is at a distance of $\dfrac{2a}{\sqrt{3}}$ from each vertex. As the triangle rotates, its center of mass shifts by $\dfrac{2a}{\sqrt{3}}\theta$, for θ << 1. Also, the vertex to which m is attached moves toward the plumb line by the distance $d = 2a\theta \cos 30° = \sqrt{3}a\theta$ (see the drawing).



Apply $\sum \vec{\tau} = 0$ about an axis through the point of suspension:

$$mg\left(a - \sqrt{3}a\theta\right) - Mg\frac{2a}{\sqrt{3}}\theta = 0$$

Solving for m/M yields:

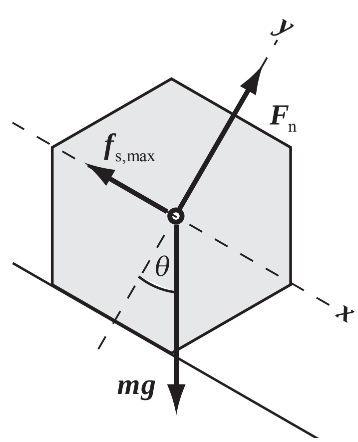
$$\frac{m}{M} = \frac{2\theta}{\sqrt{3}\left(1 - \sqrt{3}\theta\right)}$$

Substitute numerical values and evaluate m/M:

$$\frac{m}{M} = \frac{2(6.0°)\left(\dfrac{\pi\,\text{rad}}{180°}\right)}{\sqrt{3}\left[1 - \sqrt{3}(6.0°)\left(\dfrac{\pi\,\text{rad}}{180°}\right)\right]} = \boxed{0.15}$$

62 •• A standard six-sided pencil is placed on a pad of paper (Figure 12-53) Find the minimum coefficient of static friction μ_s such that, if the pad is inclined, the pencil rolls down the incline rather than sliding.

Picture the Problem If the hexagon is to roll rather than slide, the incline's angle must be such that the center of mass falls just beyond the support base. From the geometry of the hexagon, the critical angle is 30°. The free-body diagram shows the forces acting on the hexagonal pencil when it is on the verge of sliding. We can use Newton's second law to relate the coefficient of static friction to the angle of the incline for which rolling rather than sliding occurs.



Apply $\sum \vec{F} = 0$ to the pencil:

$$\sum F_x = mg\sin\theta - f_{s,max} = 0 \quad (1)$$

and

$$\sum F_y = F_n - mg\cos\theta = 0 \quad (2)$$

Substitute $f_{s,max} = \mu_s F_n$ in equation (1):

$$mg\sin\theta - \mu_s F_n = 0 \quad (3)$$

Divide equation (3) by equation (2) to obtain:

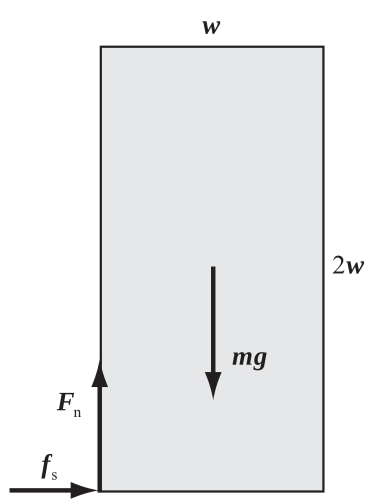
$$\tan\theta = \mu_s$$

Thus, if the pencil is to roll rather than slide when the pad is inclined:

$$\mu_s \geq \tan 30° = \boxed{0.58}$$

63 •• An 8.0-kg box that has a uniform density and is twice as tall as it is wide rests on the floor of a truck. What is the maximum coefficient of static friction between the box and floor so that the box will slide toward the rear of the truck rather than tip when the truck accelerates forward on a level road?

Picture the Problem The box and the forces acting on it are shown in the figure. The force accelerating the box is the static friction force. When the box is about to tip, F_n acts at its edge, as indicated in the drawing. We can use the definition of μ_s and apply the condition for rotational equilibrium in an accelerated frame to relate f_s to the weight of the box and, hence, to the normal force.



Using its definition, express μ_s:

$$\mu_s \geq \frac{f_s}{F_n}$$

Apply $\sum \vec{\tau} = 0$ about an axis through the box's center of mass:

$$wf_s - \tfrac{1}{2}wF_n = 0 \Rightarrow \frac{f_s}{F_n} = \frac{1}{2}$$

Substitute for f_s/F_n to obtain the condition for tipping:

$$\mu_s \geq 0.50$$

Therefore, if the box is to slide:

$$\mu_s < \boxed{0.50}$$

64 •• A balance scale has unequal arms. The scale is balanced with a 1.50-kg block on the left pan and a 1.95 kg block on the right pan (Figure 12-54). If the 1.95-kg block is removed from the right pan and the 1.50-kg block is then moved to the right pan, what mass on the left pan will balance the scale?

Picture the Problem Because the balance is in equilibrium, we can use the condition for rotational equilibrium to relate the masses of the blocks to the lever arms of the balance in the two configurations described in the problem statement.

Representing the mass of the 1.50-kg block by m_1 and the mass of the 1.95-kg block by m_2, apply $\sum\vec{\tau} = 0$ about an axis through the fulcrum:

$$m_1gL_1 - m_2gL_2 = 0$$

or

$$m_1gL_1 = m_2gL_2 \qquad (1)$$

Denoting the unknown mass as m_3, apply $\sum\vec{\tau} = 0$ about an axis through the fulcrum when the block whose mass is m_1 has been moved to the pan to the right:

$$m_1gL_2 - m_3gL_1 = 0$$

or

$$m_1gL_2 = m_3gL_1 \qquad (2)$$

Dividing equation (1) by equation (2) gives:

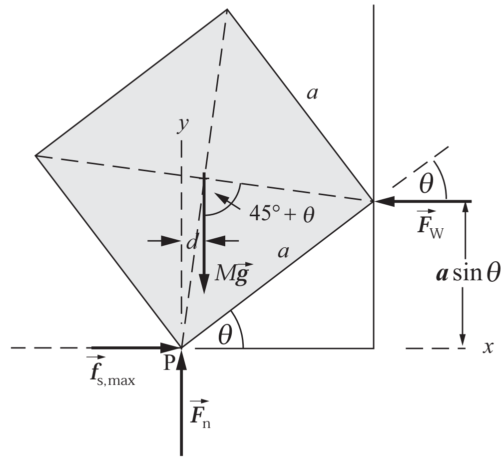
$$\frac{m_1gL_1}{m_3gL_1} = \frac{m_2gL_2}{m_1gL_2} \Rightarrow m_3 = \frac{m_1^2}{m_2}$$

Substitute numerical values and evaluate m_3:

$$M = \frac{(1.50\,\text{kg})^2}{1.95\,\text{kg}} = \boxed{1.15\,\text{kg}}$$

65 •• [SSM] A cube leans against a frictionless wall making an angle of θ with the floor as shown in Figure 12-55. Find the minimum coefficient of static friction μ_s between the cube and the floor that is needed to keep the cube from slipping.

Picture the Problem Let the mass of the cube be *M*. The figure shows the location of the cube's center of mass and the forces acting on the cube. The opposing couple is formed by the friction force $f_{s,max}$ and the force exerted by the wall. Because the cube is in equilibrium, we can use the condition for translational equilibrium to establish that $f_{s,max} = F_W$ and $F_n = Mg$ and the condition for rotational equilibrium to relate the opposing couples.



Apply $\sum\vec{F} = 0$ to the cube:

$$\sum F_y = F_n - Mg = 0 \Rightarrow F_n = Mg$$

and

$$\sum F_x = f_s - F_W = 0 \Rightarrow F_W = f_s$$

Noting that $\vec{f}_{s,max}$ and $\vec{F}_W$ form a couple (their magnitudes are equal), as do $\vec{F}_n$ and $M\vec{g}$, apply $\sum\vec{\tau} = 0$ about an axis though point P to obtain:

$$(F_W \sin\theta)a - Mg\cos(45° + \theta)\frac{a}{\sqrt{2}} = 0$$

Solving for F_W, expanding $\cos(45° + \theta)$, and simplifying gives:

$$F_W = \frac{Mg\cos(45° + \theta)\frac{a}{\sqrt{2}}}{a\sin\theta} = \frac{Mg[\cos 45°\cos\theta - \sin 45°\sin\theta]\frac{1}{\sqrt{2}}}{\sin\theta}$$

$$= \frac{Mg\left[\frac{\cos\theta}{\sqrt{2}} - \frac{\sin\theta}{\sqrt{2}}\right]\frac{1}{\sqrt{2}}}{\sin\theta} = \frac{Mg[\cos\theta - \sin\theta]}{2\sin\theta} = \frac{Mg}{2}(\cot\theta - 1)$$

Because $F_W = f_s$ and $f_s = \mu_s F_n = \mu_s Mg$:

$$\mu_s Mg = \frac{Mg}{2}(\cot\theta - 1)$$

or, solving for μ_s,

$$\mu_s = \boxed{\tfrac{1}{2}(\cot\theta - 1)}$$

66 •• Figure 12-56 shows a 5.00-kg, 1.00-m-long rod hinged to a vertical wall and supported by a thin wire. The wire and rod each make angles of 45º with the vertical. When a 10.0-kg block is suspended from the midpoint of the rod, the tension T in the supporting wire is 52.0 N. If the wire will break when the tension exceeds 75 N, what is the maximum distance from the hinge at which the block can be suspended?

Picture the Problem Because the rod is in equilibrium, we can apply the condition for rotational equilibrium to find the maximum distance from the hinge at which the block can be suspended.

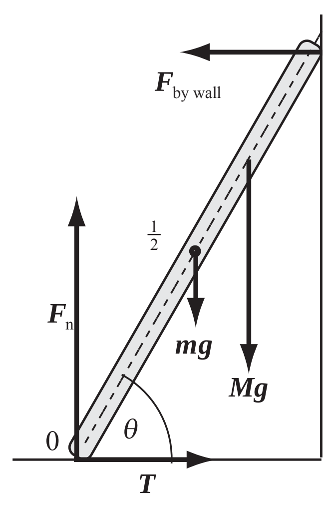
Apply $\sum\vec{\tau} = 0$ about an axis through the hinge to obtain:

$$\begin{gathered}(1.00\,\text{m})(75\,\text{N}) - (0.50\,\text{m})(5.00\,\text{kg})\left(9.81\,\text{m/s}^2\right)\cos 45° \\ -d(10.0\,\text{kg})\left(9.81\,\text{m/s}^2\right)\cos 45° = 0\end{gathered}$$

Solving for d yields: $d = \boxed{83\,\text{cm}}$

67 •• **[SSM]** Figure 12-57 shows a 20.0-kg ladder leaning against a frictionless wall and resting on a frictionless horizontal surface. To keep the ladder from slipping, the bottom of the ladder is tied to the wall with a thin wire. When no one is on the ladder, the tension in the wire is 29.4 N. (The wire will break if the tension exceeds 200 N.) (*a*) If an 80.0-kg person climbs halfway up the ladder, what force will be exerted by the ladder against the wall? (*b*) How far from the bottom end of the ladder can an 80.0-kg person climb?

Picture the Problem Let m represent the mass of the ladder and M the mass of the person. The force diagram shows the forces acting on the ladder for Part (*b*). From the condition for translational equilibrium, we can conclude that $T = F_{\text{by wall}}$, a result we'll need in Part (*b*). Because the ladder is also in rotational equilibrium, summing the torques about the bottom of the ladder will eliminate both F_n and T.



(*a*) Apply $\sum\vec{\tau} = 0$ about an axis through the bottom of the ladder:

$$F_{\text{by wall}}(\ell\sin\theta) - mg\left(\tfrac{1}{2}\ell\cos\theta\right) - Mg\left(\tfrac{1}{2}\ell\cos\theta\right) = 0$$

Solve for $F_{\text{by wall}}$ and simplify to obtain:

$$F_{\text{by wall}} = \frac{(m+M)g\cos\theta}{2\sin\theta} = \frac{(m+M)g}{2\tan\theta}$$

Refer to Figure 12-57 to determine $\tan\theta$:

$$\tan\theta = \frac{5.0\text{ m}}{1.5\text{ m}} = \frac{10}{3}$$

Substitute numerical values and evaluate $F_{\text{by wall}}$:

$$F_{\text{by wall}} = \frac{(20\text{ kg}+80\text{ kg})(9.81\text{ m/s}^2)}{2\left(\frac{10}{3}\right)} = \boxed{0.15\text{ kN}}$$

(*b*) Apply $\sum F_x = 0$ to the ladder to obtain:

$$T - F_{\text{by wall}} = 0 \Rightarrow T = F_{\text{by wall}}$$

Apply $\sum\vec{\tau} = 0$ about an axis through the bottom of the ladder subject to the condition that $F_{\text{by wall}} = T_{\text{max}}$:

$$T_{\text{max}}(\ell\sin\theta) - mg\left(\tfrac{1}{2}\ell\cos\theta\right) - Mg(L\cos\theta) = 0$$

where *L* is the maximum distance along the ladder that the person can climb without exceeding the maximum tension in the wire.

Solving for *L* and simplifying yields:

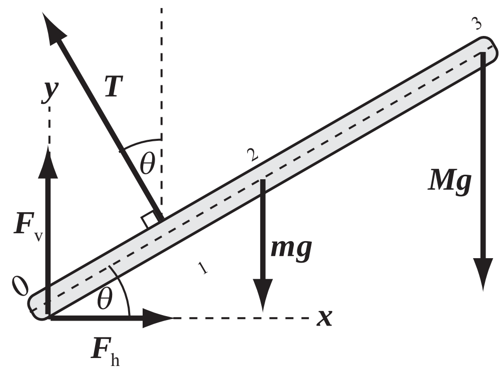
$$L = \frac{T_{\text{max}}\ell\sin\theta - \frac{1}{2}mg\ell\cos\theta}{Mg\cos\theta}$$

Substitute numerical values and evaluate *L*:

$$L = \frac{(200\text{ N})(5.0\text{ m}) - \frac{1}{2}(20\text{ kg})(9.81\text{ m/s}^2)(1.5\text{ m})}{(80\text{ kg})(9.81\text{ m/s}^2)\cos 73.3°} = \boxed{3.8\text{ m}}$$

68 •• A 360-kg object is supported on a wire attached to a 15-m-long steel bar that is pivoted at a vertical wall and supported by a cable as shown in Figure 12-58. The mass of the bar is 85 kg. With the cable attached to the bar 5.0 m from the lower end as shown, find the tension in the cable and the force exerted by the wall on the steel bar.

Picture the Problem Let m represent the mass of the bar, M the mass of the suspended object, F_v the vertical component of the force the wall exerts on the bar, F_h the horizontal component of the force the wall exerts on the bar, and T the tension in the cable. The force diagram shows these forces and their points of application on the bar. Because the bar is in equilibrium, we can apply the conditions for translational and rotational equilibrium to relate the various forces and distances.



Apply $\sum \vec{\tau} = 0$ to the bar about an axis through the hinge:

$$T\ell_1 - mg\ell_2 \cos\theta - Mg\ell_3 \cos\theta = 0$$

Solving for T yields:

$$T = \frac{(m\ell_2 + M\ell_3)g\cos\theta}{\ell_1}$$

Substitute numerical values and evaluate T:

$$T = \frac{((85\,\text{kg})(7.5\,\text{m}) + (360\,\text{kg})(15\,\text{m}))(9.81\,\text{m/s}^2)\cos 30°}{5.0\,\text{m}} = 10.3\,\text{kN} = \boxed{10\,\text{kN}}$$

The magnitude and direction of the force exerted by the wall are given by:

$$F_{\text{by wall}} = \sqrt{F_v^2 + F_h^2} \quad (1)$$

and

$$\phi = \tan^{-1}\left(\frac{F_v}{F_h}\right) \quad (2)$$

Apply $\sum \vec{F} = 0$ to the bar to obtain:

$$\sum F_y = F_v + T\cos 30° - mg - Mg = 0$$

and

$$\sum F_x = F_h - T\sin 30° = 0$$

Solving the y equation for F_v yields:

$$F_v = (m + M)g - T\cos 30°$$

Solve the x equation for F_h to obtain:

$$F_h = T\sin 30°$$

Substituting for F_v and F_h in equation (1) yields:

$$F_{\text{by wall}} = \sqrt{\left((m+M)g - T\cos 30°\right)^2 + \left(T\sin 30°\right)^2}$$

Substitute numerical values and evaluate $F_{\text{by wall}}$:

$$\begin{aligned}F_{\text{by wall}} &= \sqrt{\left((85\text{ kg}+360\text{ kg})(9.81\text{ m/s}^2) - (10.3\text{ kN})\cos 30°\right)^2 + \left((10.3\text{ kN})\sin 30°\right)^2}\\ &= \boxed{6.9\text{ kN}}\end{aligned}$$

Substituting for F_v and F_h in equation (2) yields:

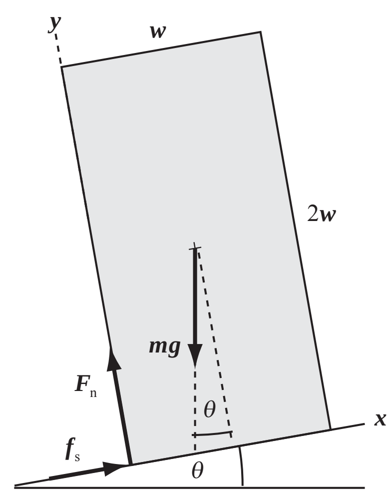
$$\phi = \tan^{-1}\left(\frac{(m+M)g - T\cos 30°}{T\sin 30°}\right)$$

Substitute numerical values and evaluate ϕ:

$$\begin{aligned}\phi &= \tan^{-1}\left(\frac{(85\text{ kg}+360\text{ kg})(9.81\text{ m/s}^2) - (10.3\text{ kN})\cos 30°}{(10.3\text{ kN})\sin 30°}\right) = -41.49°\\ &= \boxed{-41°}\text{ That is, }41°\text{ below the horizontal.}\end{aligned}$$

69 •• Repeat Problem 63 if the truck accelerates up a hill that makes an angle of 9.0º with the horizontal.

Picture the Problem The box and the forces acting on it are shown in the figure. When the box is about to tip, F_n acts at its edge, as indicated in the drawing. We can use the definition of μ_s and apply the condition for rotational equilibrium in an accelerated frame to relate f_s to the weight of the box and, hence, to the normal force.



Using its definition, express μ_s:

$$\mu_s \geq \frac{f_s}{F_n}$$

Apply $\sum \vec{\tau} = 0$ about an axis through the box's center of mass:

$$wf_s - \tfrac{1}{2}wF_n = 0 \Rightarrow \frac{f_s}{F_n} = \frac{1}{2}$$

Substitute for $\dfrac{f_s}{F_n}$ to obtain the condition for tipping:

$$\mu_s \geq 0.50$$

Therefore, if the box is to slide:

$$\mu_s < \boxed{0.50}\text{, as in Problem 63.}$$

Remarks: The difference between problems 63 and 69 is that in 63 the maximum acceleration before slipping is 0.5*g*, whereas in 69 it is (0.5 cos9.0°– sin9.0°)*g* = 0.337*g*.

70 •• A thin uniform rod 60 cm long is balanced 20 cm from one end when an object whose mass is (2*m* + 2.0 grams) is at the end nearest the pivot and an object of mass *m* is at the opposite end (Figure 12-59*a*). Balance is again achieved if the object whose mass is (2*m* + 2.0 grams) is replaced by the object of mass *m* and no object is placed at the other end (Figure 12-59*b*). Determine the mass of the rod.

Picture the Problem Let the mass of the rod be represented by *M*. Because the rod is in equilibrium, we can apply the condition for rotational equilibrium to relate the masses of the objects placed on the rod to its mass.

Apply $\sum \vec{\tau} = 0$ about an axis through the pivot for the initial condition:

$$(20\,\text{cm})(2m + 2.0\,\text{g}) - (40\,\text{cm})m - (10\,\text{cm})M = 0$$

Simplifying yields:

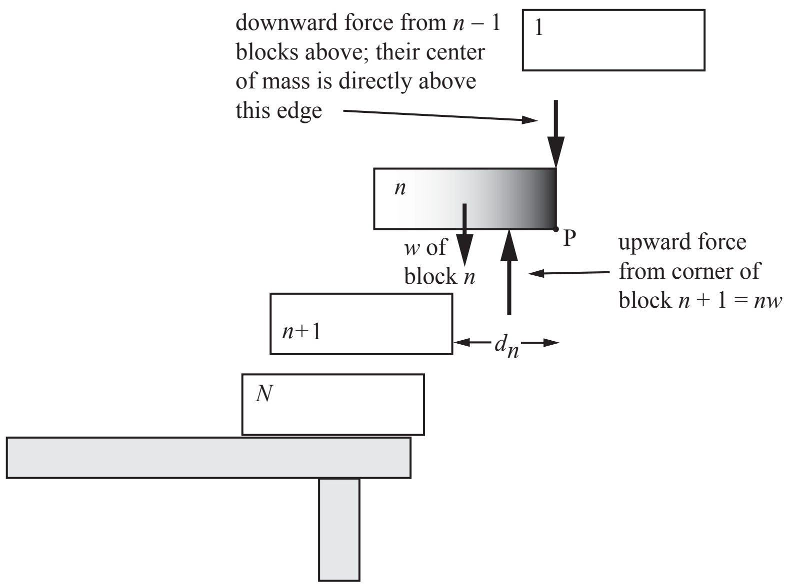
$$2(2m + 2.0\,\text{g}) - 4m - M = 0$$

Solve for *M* to obtain:

$$M = \boxed{4.0\,\text{g}}$$

71 ••• [SSM] There are a large number of identical uniform bricks, each of length *L*. If they are stacked one on top of another lengthwise (see Figure 12-63), the maximum offset that will allow the top brick to rest on the bottom brick is *L*/2. (*a*) Show that if this two-brick stack is placed on top of a third brick, the maximum offset of the second brick on the third brick is *L*/4. (*b*) Show that, in general, if you build a stack of *N* bricks, the maximum overhang of the (*n* – 1)th brick (counting down from the top) on the *n*th brick is *L*/2*n*. (*c*) Write a **spreadsheet** program to calculate total offset (the sum of the individual offsets) for a stack of *N* bricks, and calculate this for *L* = 20 cm and *N* = 5, 10, and 100. (*d*) Does the sum of the individual offsets approach a finite limit as $N \to \infty$? If so, what is that limit?

Picture the Problem Let the weight of each uniform brick be w. The downward force of all the bricks above the nth brick *must act at its corner,* because the upward reaction force points through the center of mass of all the bricks above the nth one. Because there is no vertical acceleration, the upward force exerted by the $(n + 1)$th brick on the nth brick must equal the total weight of the bricks above it. Thus this force is just nw. Note that it is convenient to develop the general relationship of Part (b) initially and then extract the answer for Part (a) from this general result.



(a) and (b) Noting that the line of action of the downward forces exerted by the blocks above the nth block passes through the point P, resulting in a lever arm of zero, apply $\sum \tau_{\text{P}} = 0$ to the nth brick to obtain:

$$w\left(\tfrac{1}{2}L\right) - nwd_n = 0$$

where d_n is the overhang of the nth brick beyond the edge of the $(n + 1)$th brick.

Solving for d_n yields:

$$d_n = \boxed{\frac{L}{2n}} \text{ where } n = 1,2,3,\ldots$$

For block number 2:

$$d_2 = \boxed{\frac{L}{4}}$$

(c) A spreadsheet program to calculate the sum of the offsets as a function of n is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B5	B4+1	$n+1$
C5	C4+$B$1/(2*B5)	$d_n + \dfrac{L}{2n}$

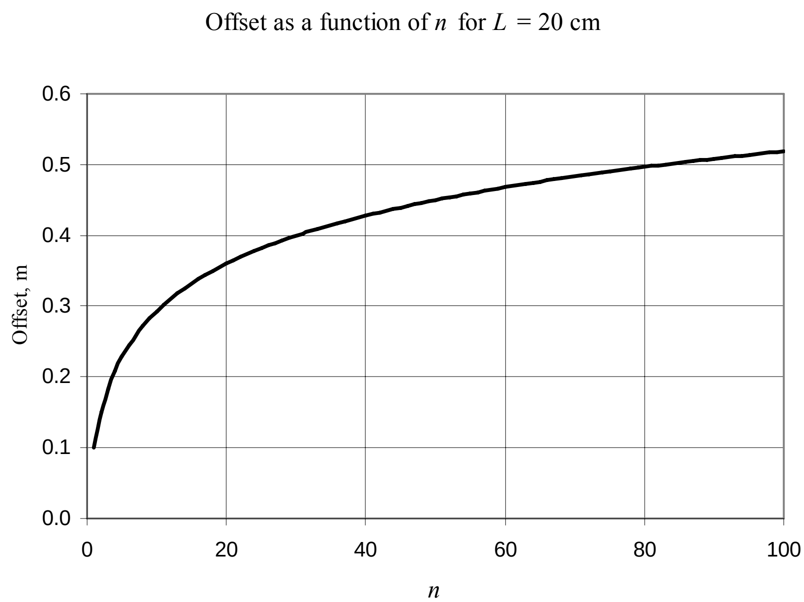
	A	B	C	D
1	$L=$	0.20	m	
2				
3		n	offset	
4		1	0.100	
5		2	0.150	
6		3	0.183	
7		4	0.208	
8		5	0.228	
9		6	0.245	
10		7	0.259	
11		8	0.272	
12		9	0.283	
13		10	0.293	
98		95	0.514	
99		96	0.515	
100		97	0.516	
101		98	0.517	
102		99	0.518	
103		100	0.519	

From the table we see that $d_5 = \boxed{15\,\text{cm},}$ $d_{10} = \boxed{26\,\text{cm},}$ and $d_{100} = \boxed{52\,\text{cm}.}$

(*d*) The sum of the individual offsets S is given by:

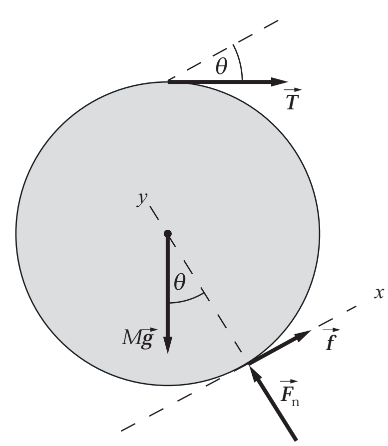
$$S = \sum_{n=1}^{N} d_n = \frac{L}{2}\sum_{n=1}^{N}\frac{1}{n}$$

No. Because this series is a harmonic series, S approaches infinity as the number of blocks N grows without bound. The following graph, plotted using a spreadsheet program, suggests that S has no limit.



72 •• A uniform sphere of radius R and mass M is held at rest on an inclined plane of angle θ by a horizontal string, as shown in Figure 12-61. Let R = 20 cm, M = 3.0 kg, and θ = 30º. (*a*) Find the tension in the string. (*b*) What is the normal force exerted on the sphere by the inclined plane? (*c*) What is the frictional force acting on the sphere?

Picture the Problem The four forces acting on the sphere: its weight, *mg*; the normal force of the plane, F_n; the frictional force, *f*, acting parallel to the plane; and the tension in the string, *T*, are shown in the figure. Because the sphere is in equilibrium, we can apply the conditions for translational and rotational equilibrium to find *f*, F_n, and *T*.



(*a*) Apply $\sum\vec{\tau} = 0$ about an axis through the center of the sphere:

$$fR - TR = 0 \Rightarrow T = f$$

Apply $\sum F_x = 0$ to the sphere:

$$f + T\cos\theta - Mg\sin\theta = 0$$

Substituting for f and solving for T yields:

$$T = \frac{Mg\sin\theta}{1+\cos\theta}$$

Substitute numerical values and evaluate T:

$$T = \frac{(3.0\,\text{kg})(9.81\,\text{m/s}^2)\sin 30°}{1+\cos 30°} = 7.89\,\text{N}$$
$$= \boxed{7.9\,\text{N}}$$

(b) Apply $\sum F_y = 0$ to the sphere:

$$F_n - T\sin\theta - Mg\cos\theta = 0$$

Solve for F_n:

$$F_n = T\sin\theta + Mg\cos\theta$$

Substitute numerical values and evaluate F_n:

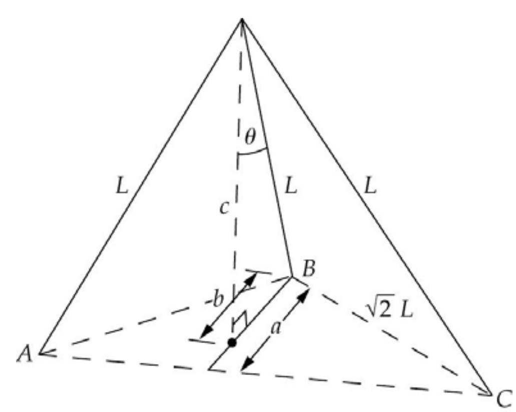
$$F_n = (7.89\,\text{N})\sin 30° + (3.0\,\text{kg})(9.81\,\text{m/s}^2)\cos 30° = \boxed{29\,\text{N}}$$

(c) In Part (a) we showed that $f = T$:

$$f = \boxed{7.9\,\text{N}}$$

73 ••• The legs of a tripod make equal angles of 90º with each other at the apex, where they join together. A 100-kg block hangs from the apex. What are the compressional forces in the three legs?

Picture the Problem Let L be the length of each leg of the tripod. Applying the Pythagorean theorem leads us to conclude that the distance a shown in the figure is $\sqrt{3/2}L$ and the distance b, the distance to the centroid of the triangle ABC is $\frac{2}{3}\sqrt{3/2}L$, and the distance c is $L/\sqrt{3}$. These results allow us to conclude that $\cos\theta = L/\sqrt{3}$. Because the tripod is in equilibrium, we can apply the condition for translational equilibrium to find the compressional forces in each leg.



Letting F_C represent the compressional force in a leg of the tripod, apply $\sum \vec{F} = 0$ to the apex of the tripod:

$$3F_C\cos\theta - mg = 0 \Rightarrow F_C = \frac{mg}{3\cos\theta}$$

Substitute for $\cos\theta$ and simplify to obtain:

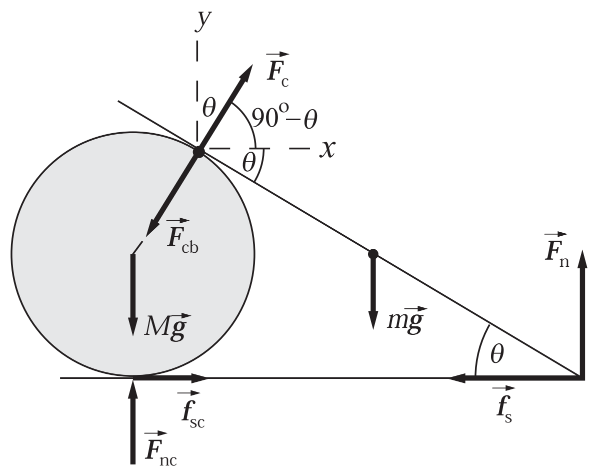
$$F_C = \frac{mg}{3\left(\frac{1}{\sqrt{3}}\right)} = \frac{mg}{\sqrt{3}}$$

Substitute numerical values and evaluate F_C:

$$F_C = \frac{(100\,\text{kg})(9.81\,\text{m/s}^2)}{\sqrt{3}} = \boxed{566\,\text{N}}$$

74 ••• Figure 12-63 shows a 20-cm-long uniform beam resting on a cylinder that has a radius of 4.0-cm. The mass of the beam is 5.0 kg and that of the cylinder is 8.0 kg. The coefficient of static friction between beam and cylinder is zero, whereas the coefficients of static friction between the cylinder and the floor, and between the beam and the floor, are *not* zero. Are there any values for these coefficients of static friction such that the system is in static equilibrium? If so, what are these values? If not, explain why none exist.

Picture the Problem The forces that act on the beam are its weight, mg; the force of the cylinder, F_c, acting along the radius of the cylinder; the normal force of the ground, F_n; and the friction force $f_s = \mu_s F_n$. The forces acting on the cylinder are its weight, Mg; the force of the beam on the cylinder, $F_{cb} = F_c$ in magnitude, acting radially inward; the normal force of the ground on the cylinder, F_{nc}; and the force of friction, $f_{sc} = \mu_{sc} F_{nc}$. Choose the coordinate system shown in the figure and apply the conditions for rotational and translational equilibrium.



Express $\mu_{s,\text{beam-floor}}$ in terms of f_s and F_n:

$$\mu_{s,\text{beam-floor}} = \frac{f_s}{F_n} \quad (1)$$

Express $\mu_{s,\text{cylinder-floor}}$ in terms of f_{sc} and F_{nc}:

$$\mu_{s,\text{cylinder-floor}} = \frac{f_{sc}}{F_{nc}} \quad (2)$$

Apply $\sum \vec{\tau} = 0$ about an axis through the right end of the beam:

$$[(10\,\text{cm})\cos\theta]mg - (15\,\text{cm})F_\text{c} = 0$$

Solve for F_c to obtain:

$$F_\text{c} = \frac{[(10\,\text{cm})\cos\theta]mg}{15\,\text{cm}}$$

Substitute numerical values and evaluate F_c:

$$F_\text{c} = \frac{[10\cos 30°](5.0\,\text{kg})(9.81\,\text{m/s}^2)}{15} = 28.3\,\text{N}$$

Apply $\sum F_y = 0$ to the beam:

$$F_\text{n} + F_\text{c}\cos\theta - mg = 0$$

Solving for F_n yields:

$$F_\text{n} = mg - F_\text{c}\cos\theta$$

Substitute numerical values and evaluate F_n:

$$F_\text{n} = (5.0\,\text{kg})(9.81\,\text{m/s}^2) - (28.3\,\text{N})\cos 30° = 24.5\,\text{N}$$

Apply $\sum F_x = 0$ to the beam:

$$-f_\text{s} + F_\text{c}\cos(90° - \theta) = 0$$

Solve for f_s to obtain:

$$f_\text{s} = F_\text{c}\cos(90° - \theta)$$

Substitute numerical values and evaluate f_s:

$$f_\text{s} = F_\text{c}\cos(90° - \theta) = (28.3\,\text{N})\cos 60° = 14.2\,\text{N}$$

$\vec{F}_\text{cb}$ is the reaction force to $\vec{F}_\text{c}$:

$F_\text{cb} = F_\text{c} = 28.3\,\text{N}$ radially inward.

Apply $\sum F_y = 0$ to the cylinder:

$$F_\text{nc} - F_\text{cb}\cos\theta - Mg = 0$$

Solve for F_nc to obtain:

$$F_\text{nc} = F_\text{cb}\cos\theta + Mg$$

Substitute numerical values and evaluate F_nc:

$$F_\text{nc} = (28.3\,\text{N})\cos 30° + (8.0\,\text{kg})(9.81\,\text{m/s}^2) = 103\,\text{N}$$

Apply $\sum F_x = 0$ to the cylinder:

$$f_\text{sc} - F_\text{cb}\cos(90° - \theta) = 0$$

Solve for and evaluate f_sc:

$$f_\text{sc} = F_\text{cb}\cos(90° - \theta) = (28.3\,\text{N})\cos 60° = 14.2\,\text{N}$$

Substitute numerical values in equations (1) and (2) and evaluate $\mu_{\text{s,beam-floor}}$ and $\mu_{\text{s,cylinder-floor}}$:

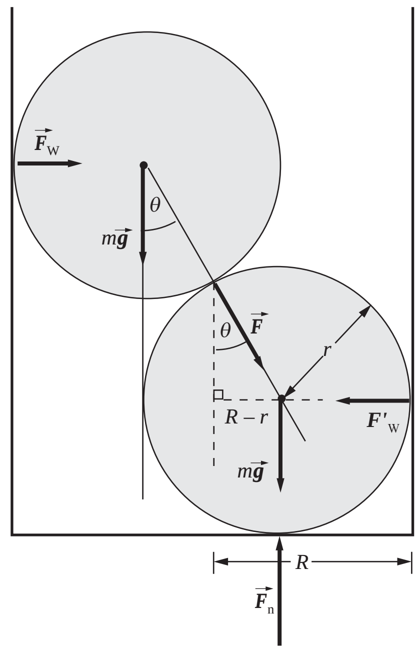
$$\mu_{\text{s,beam-floor}} = \frac{14.2\ \text{N}}{24.5\ \text{N}} = \boxed{0.58}$$

and

$$\mu_{\text{s,cylinder-floor}} = \frac{14.2\ \text{N}}{103\ \text{N}} = \boxed{0.14}$$

75 ••• [SSM] Two solid smooth (frictionless) spheres of radius r are placed inside a cylinder of radius R, as in Figure 12-62. The mass of each sphere is m. Find the force exerted by the bottom of the cylinder on the bottom sphere, the force exerted by the wall of the cylinder on each sphere, and the force exerted by one sphere on the other. All forces should be expressed in terms of m, R, and r.

Picture the Problem The geometry of the system is shown in the drawing. Let upward be the positive y direction and to the right be the $+x$ direction. Let the angle between the vertical center line and the line joining the two centers be θ. Then $\sin\theta = \dfrac{R-r}{r}$ and $\tan\theta = \dfrac{R-r}{\sqrt{R(2r-R)}}$. The force exerted by the bottom of the cylinder is just $2mg$. Let F be the force that the top sphere exerts on the lower sphere. Because the spheres are in equilibrium, we can apply the condition for translational equilibrium.



Apply $\sum F_y = 0$ to the spheres:

$$F_n - mg - mg = 0 \Rightarrow F_n = \boxed{2mg}$$

Because the cylinder wall is smooth, $F\cos\theta = mg$, and:

$$F = \frac{mg}{\cos\theta} = \boxed{mg\frac{r}{\sqrt{R(2r-R)}}}$$

Express the x component of F:

$$F_x = F\sin\theta = mg\tan\theta$$

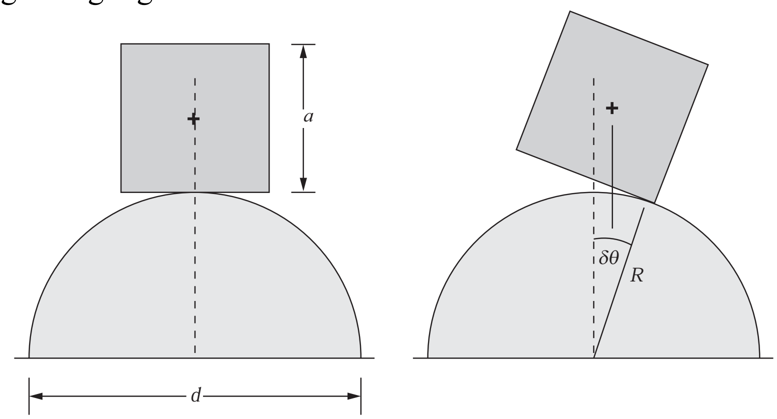
Express the force that the wall of the cylinder exerts:

$$F_W = \boxed{mg\frac{R-r}{\sqrt{R(2r-R)}}}$$

Remarks: Note that as *r* approaches *R*/2, $F_w \rightarrow \infty$.

76 ••• A solid cube of side length a balanced atop a cylinder of diameter d is in unstable equilibrium if $d << a$ (Figure 12-64) and is in stable equilibrium if $d >> a$. The cube does not slip on the cylinder. Determine the minimum value of the ratio d/a for which the cube is in stable equilibrium.

Picture the Problem Consider a small rotational displacement, $\delta\theta$ of the cube from equilibrium. This shifts the point of contact between cube and cylinder by $R\delta\theta,$ where $R = d/2$. As a result of that motion, the cube itself is rotated through the same angle $\delta\theta,$ and so its center is shifted in the same direction by the amount $(a/2)\,\delta\theta,$ neglecting higher order terms in $\delta\theta$.



If the displacement of the cube's center of mass is less than that of the point of contact, the torque about the point of contact is a restoring torque, and the cube will return to its equilibrium position. If, on the other hand, $(a/2)\,\delta\theta > (d/2)\,\delta\theta,$ then the torque about the point of contact due to mg is in the direction of $\delta\theta,$ and will cause the displacement from equilibrium to increase. We see that the minimum value of d/a for stable equilibrium is $d/a = 1$.

Chapter 13
Fluids

Conceptual Problems

1 • If the gauge pressure is doubled, the absolute pressure will be (*a*) halved, (*b*) doubled, (*c*) unchanged, (*d*) increased by a factor greater than 2, (*e*) increased by a factor less than 2.

Determine the Concept The absolute pressure is related to the gauge pressure according to $P = P_{\text{gauge}} + P_{\text{at}}$.

Prior to doubling the gauge pressure, the absolute pressure is given by:

$$P = P_{\text{gauge}} + P_{\text{at}} \Rightarrow P_{\text{gauge}} = P - P_{\text{at}}$$

Doubling the gauge pressure results in an absolute pressure given by:

$$P' = 2P_{\text{gauge}} + P_{\text{at}}$$

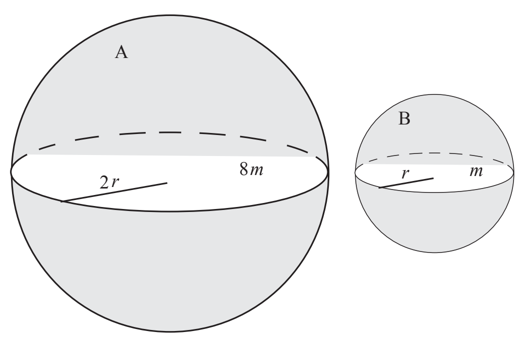
Substituting for P_{gauge} yields:

$$P' = 2(P - P_{\text{at}}) + P_{\text{at}} = 2P - P_{\text{at}}$$

Because $P' = 2P - P_{\text{at}}$, doubling the gauge pressure results in an increase in the absolute pressure by a factor less than 2. $\boxed{(e)}$ is correct.

2 • Two spherical objects differ in size and mass. Object A has a mass that is eight times the mass of object B. The radius of object A is twice the radius of object B. How do their densities compare? (*a*) $\rho_{\text{A}} > \rho_{\text{B}}$, (*b*) $\rho_{\text{A}} < \rho_{\text{B}}$, (*c*) $\rho_{\text{A}} = \rho_{\text{B}}$, (*d*) not enough information is given to compare their densities.

Determine the Concept The density of an object is its mass per unit volume. The pictorial representation shown to the right summarizes the information concerning the radii and masses of the two spheres. We can determine the relationship between the densities of A and B by examining their ratio.



Express the densities of the two spheres:

$$\rho_{\text{A}} = \frac{m_{\text{A}}}{V_{\text{A}}} = \frac{m_{\text{A}}}{\frac{4}{3}\pi r_{\text{A}}^3}$$

and

$$\rho_{\text{B}} = \frac{m_{\text{B}}}{V_{\text{B}}} = \frac{m_{\text{B}}}{\frac{4}{3}\pi r_{\text{B}}^3}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{\rho_A}{\rho_B}=\frac{\dfrac{m_A}{\frac{4}{3}\pi r_A^3}}{\dfrac{m_B}{\frac{4}{3}\pi r_B^3}}=\frac{m_A}{m_B}\frac{r_B^3}{r_A^3}$$

Substituting for the masses and radii and simplifying yields:

$$\frac{\rho_A}{\rho_B}=\frac{8m}{m}\frac{r^3}{(2r)^3}=1\Rightarrow\rho_A=\rho_B$$

and $\boxed{(c)}$ is correct.

3 • **[SSM]** Two objects differ in density and mass. Object A has a mass that is eight times the mass of object B. The density of object A is four times the density of object B. How do their volumes compare? (*a*) $V_A=\frac{1}{2}V_B$, (*b*) $V_A=V_B$, (*c*) $V_A=2V_B$, (*d*) not enough information is given to compare their volumes.

Determine the Concept The density of an object is its mass per unit volume. We can determine the relationship between the volumes of A and B by examining their ratio.

Express the volumes of the two objects:

$$V_A=\frac{m_A}{\rho_A}\text{ and }V_B=\frac{m_B}{\rho_B}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{V_A}{V_B}=\frac{\dfrac{m_A}{\rho_A}}{\dfrac{m_B}{\rho_B}}=\frac{\rho_B}{\rho_A}\frac{m_A}{m_B}$$

Substituting for the masses and densities and simplifying yields:

$$\frac{V_A}{V_B}=\frac{\rho_B}{4\rho_B}\frac{8m_B}{m_B}=2\Rightarrow V_A=2V_B$$

and $\boxed{(c)}$ is correct.

4 • A sphere is constructed by gluing together two hemispheres of different density materials. The density of each hemisphere is uniform, but the density of one is greater than the density of the other. True or false: The average density of the sphere is the numerical average of the two different densities. Clearly explain your reasoning.

Determine the Concept True. This is a special case. Because the volumes are equal, the average density is the numerical average of the two densities. ***This is not a general result.***

5 • In several jungle adventure movies, the hero and heroine escape the bad guys by hiding underwater for extended periods of time. To do this, they breathe through long vertical hollow reeds. Imagine that in one movie, the water is so clear that to be safely hidden the two are at a depth of 15 m. As a science consultant to the movie producers, you tell them that this is not a realistic depth and the knowledgeable viewer will laugh during this scene. Explain why this is so.

Determine the Concept Pressure increases approximately 1 atm every 10 m in fresh water. To breathe requires creating a pressure of less than 1 atm in your lungs. At the surface you can do this easily, but not at a depth of 10 m.

6 •• Two objects are balanced as in Figure 13-28. The objects have identical volumes but different masses. Assume all the objects in the figure are denser than water and thus none will float. Will the equilibrium be disturbed if the entire system is completely immersed in water? Explain your reasoning.

Determine the Concept Yes. Because the volumes of the two objects are equal, the downward force on each side is reduced by the same amount (the buoyant force acting on them) when they are submerged. The buoyant force is independent of their masses. That is, if $m_1L_1 = m_2L_2$ and $L_1 \neq L_2$, then $(m_1 - c)L_1 \neq (m_2 - c)L_2$.

7 •• **[SSM]** A solid 200-g block of lead and a solid 200-g block of copper are completely submerged in an aquarium filled with water. Each block is suspended just above the bottom of the aquarium by a thread. Which of the following is true?

(*a*) The buoyant force on the lead block is greater than the buoyant force on the copper block.
(*b*) The buoyant force on the copper block is greater than the buoyant force on the lead block.
(*c*) The buoyant force is the same on both blocks.
(*d*) More information is needed to choose the correct answer.

Determine the Concept The buoyant forces acting on these submerged objects are equal to the weight of the water each displaces. The weight of the displaced water, in turn, is directly proportional to the volume of the submerged object. Because $\rho_{Pb} > \rho_{Cu}$, the volume of the copper must be greater than that of the lead and, hence, the buoyant force on the copper is greater than that on the lead. $\boxed{(b)}$ is correct.

8 •• A 20-cm^3 block of lead and a 20-cm^3 block of copper are completely submerged in an aquarium filled with water. Each is suspended just above the bottom of the aquarium by a thread. Which of the following is true?

(*a*) The buoyant force on the lead block is greater than the buoyant force on the copper block..
(*b*) The buoyant force on the copper block is greater than the buoyant force on the lead block.
(*c*) The buoyant force is the same on both blocks.
(*d*) More information is needed to choose the correct answer.

Determine the Concept The buoyant forces acting on these submerged objects are equal to the weight of the water each displaces. The weight of the displaced water, in turn, is directly proportional to the volume of the submerged object. Because their volumes are the same, the buoyant forces on them must be the same. $\boxed{(c)}$ is correct.

9 •• Two bricks are completely submerged in water. Brick 1 is made of lead and has rectangular dimensions of 2″ × 4″ × 8″. Brick 2 is made of wood and has rectangular dimensions of 1″ × 8″ × 8″. *True or false*: The buoyant force on brick 2 is larger than the buoyant force on brick 1.

Determine the Concept False. The buoyant force on a submerged object depends on the weight of the displaced fluid which, in turn, depends on the volume of the displaced fluid. Because the bricks have the same volume, they will displace the same volume of water and the buoyant force will be the same on both of them.

10 •• Figure 13-29 shows an object called a ″Cartesian diver.″ The diver consists of a small tube, open at the bottom, with an air bubble at the top, inside a closed plastic soda bottle that is partly filled with water. The diver normally floats, but sinks when the bottle is squeezed hard. (*a*) Explain why this happens. (*b*) Explain the physics behind how a submarine can ″silently″ sink vertically simply by allowing water to flow into empty tanks near its keel. (*c*) Explain why a floating person will oscillate up and down on the water surface as he or she breathes in and out.

Determine the Concept

(*a*) When the bottle is squeezed, the force is transmitted equally through the fluid, leading to a pressure increase on the air bubble in the diver. The air bubble shrinks, and the loss in buoyancy is enough to sink the diver.

(*b*) As water enters its tanks, the weight of the submarine increases. When the submarine is completely submerged, the volume of the displaced water and, hence, the buoyant force acting on the submarine become constant. Because the weight of the submarine is now greater than the buoyant force acting on it, the submarine will start to sink.

(*c*) Breathing in lowers one's average density and breathing out increases one's average density. Because denser objects float lower on the surface than do less dense objects, a floating person will oscillate up and down on the water surface as he or she breathes in and out.

11 •• A certain object has a density just slightly less than that of water so that it floats almost completely submerged. However, the object is more compressible than water. What happens if the floating object is given a slight downward push? Explain.

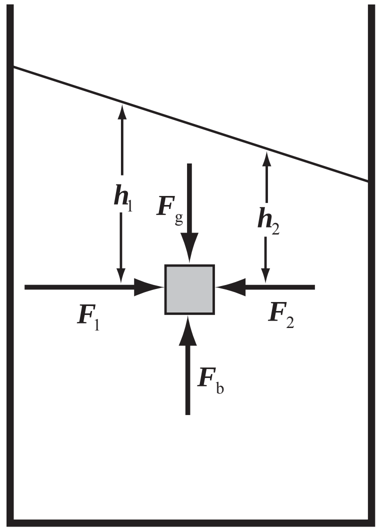
Determine the Concept Because the pressure increases with depth, the object will be compressed and its density will increase as its volume decreases. Thus, the object will sink to the bottom.

12 •• In Example 13.11 the fluid is accelerated to a greater speed as it enters the narrow part of the pipe. Identify the forces that act on the fluid at the entrance to the narrow region to produce this acceleration.

Determine the Concept The acceleration-producing force acting on the fluid is the product of the difference in pressure between the wide and narrow parts of the pipe and the area of the narrow part of the pipe.

13 •• **[SSM]** An upright glass of water is accelerating to the right along a flat, horizontal surface. What is the origin of the force that produces the acceleration on a small element of water in the middle of the glass? Explain by using a diagram. *Hint: The water surface will not remain level as long as the glass of water is accelerating. Draw a free body diagram of the small element of water.*

Determine the Concept The pictorial representation shows the glass and an element of water in the middle of the glass. As is readily established by a simple demonstration, the surface of the water is not level while the glass is accelerated, showing that there is a pressure gradient (a difference in pressure) due to the differing depths ($h_1 > h_2$ and hence $F_1 > F_2$) of water on the two sides of the element of water. This pressure gradient results in a net force on the element as shown in the figure. The upward buoyant force is equal in magnitude to the downward gravitational force.



14 •• You are sitting in a boat floating on a very small pond. You take the anchor out of the boat and drop it into the water. Does the water level in the pond rise, fall, or remain the same? Explain your answer.

Determine the Concept The water level in the pond will fall slightly. When the anchor is in the boat, the boat displaces enough water so that the buoyant force on it equals the sum of the weight of the boat, your weight, and the weight of the anchor. When you drop the anchor into the water, it displaces just its volume of water (rather than its weight as it did while in the boat). The total weight of the boat becomes less and the boat displaces less water as a consequence.

15 •• A horizontal pipe narrows from a diameter of 10 cm at location A to 5.0 cm at location B. For a nonviscous incompressible fluid flowing without turbulence from location A to location B, how do the flow speeds v (in m/s) at the two locations compare? (*a*) $v_A = v_B$, (*b*) $v_A = \frac{1}{2}v_B$, (*c*) $v_A = \frac{1}{4}v_B$, (*d*) $v_A = 2v_B$, (*e*) $v_A = 4v_B$

Determine the Concept We can use the equation of continuity to compare the flow rates at the two locations.

Apply the equation of continuity at locations A and B to obtain:

$$A_A v_A = A_B v_B \Rightarrow v_A = \frac{A_B}{A_A} v_B$$

Substitute for A_B and A_A and simplify to obtain:

$$v_A = \frac{\frac{1}{4}\pi d_B^2}{\frac{1}{4}\pi d_A^2} v_B = \left(\frac{d_B}{d_A}\right)^2 v_B$$

Substitute numerical values and evaluate v_A:

$$v_A = \left(\frac{5\text{ cm}}{10\text{ cm}}\right)^2 v_B = \tfrac{1}{4}v_B$$

and $\boxed{(c)}$ is correct.

16 •• A horizontal pipe narrows from a diameter of 10 cm at location A to 5.0 cm at location B. For a nonviscous incompressible fluid flowing without turbulence from location A to location B, how do the pressures P (in N/m^2) at the two locations compare? (*a*) $P_A = P_B$, (*b*) $P_A = \frac{1}{2}P_B$, (*c*) $P_A = \frac{1}{4}P_B$, (*d*) $P_A = 2P_B$, (*e*) $P_A = 4P_B$, (*f*) There is not enough information to compare the pressures quantitatively.

Determine the Concept We can use the equation of continuity to compare the flow rates at the two locations.

Apply Bernoulli's equation for constant elevations at locations A and B to obtain:

$$P_A + \tfrac{1}{2}\rho v_A^2 = P_B + \tfrac{1}{2}\rho v_B^2 \qquad (1)$$

Apply the equation of continuity at locations A and B to obtain:

$$A_A v_A = A_B v_B \Rightarrow v_A = \frac{A_B}{A_A}v_B$$

Substitute for A_B and A_A and simplify to obtain:

$$v_A = \frac{\frac{1}{4}\pi d_B^2}{\frac{1}{4}\pi d_A^2}v_B = \left(\frac{d_B}{d_A}\right)^2 v_B$$

Substituting for v_A in equation (1) yields:

$$P_A + \tfrac{1}{2}\rho\left(\left(\frac{d_B}{d_A}\right)^2 v_B\right)^2 = P_B + \tfrac{1}{2}\rho v_B^2$$

While the values of d_B, d_A, and ρ are known to us, we need a value for v_B (or v_A) in order to compare P_A and P_B. Hence $\boxed{(f)}$ is correct.

17 •• **[SSM]** Figure 13-30 is a diagram of a prairie dog tunnel. The geometry of the two entrances are such that entrance 1 is surrounded by a mound and entrance 2 is surrounded by flat ground. Explain how the tunnel remains ventilated, and indicate in which direction air will flow through the tunnel.

Determine the Concept The mounding around entrance 1 will cause the streamlines to curve concave downward over the entrance. An upward pressure gradient produces the downward centripetal force. This means there is a lowering of the pressure at entrance 1. No such lowering occurs aver entrance 2, so the pressure there is higher than the pressure at entrance 1. The air circulates in entrance 2 and out entrance 1. It has been demonstrated that enough air will circulate inside the tunnel even with slightest breeze outside.

Estimation and Approximation

18 •• Your undergraduate research project involves atmospheric sampling. The sampling device has a mass of 25.0 kg. Estimate the diameter of a helium-filled balloon required to lift the device off the ground. Neglect the mass of the balloon ″skin″ and the small buoyancy force on the device itself.

Picture the Problem We can use Archimedes' principle and the condition for vertical equilibrium to estimate the diameter of the helium-filled balloon that would just lift the sampling device.

Express the equilibrium condition that must be satisfied if the balloon-payload is to ″just lift off″:

$$F_{\text{bouyant}} = B = F_{\text{gravitational}} = mg \qquad (1)$$

Using Archimedes' principle, express the buoyant force B:

$$B = w_{\text{displaced fluid}} = m_{\text{displaced fluid}}g$$
$$= \rho_{\text{air}}V_{\text{balloon}}g$$

Substituting for B in equation (1) yields:

$$\rho_{\text{air}}V_{\text{balloon}}g = mg$$
or
$$\rho_{\text{air}}V_{\text{balloon}} = m \qquad (2)$$

The total mass m to be lifted is the sum of the mass of the payload m_{p} and the mass of the helium m_{He}:

$$m = m_{\text{p}} + m_{\text{He}} = m_{\text{p}} + \rho_{\text{He}}V_{\text{balloon}}$$

Substitute for m in equation (2) to obtain:

$$\rho_{\text{air}}V_{\text{balloon}} = m_{\text{p}} + \rho_{\text{He}}V_{\text{balloon}}$$

Solving for V_{balloon} yields:

$$V_{\text{balloon}} = \frac{m_{\text{p}}}{\rho_{\text{air}} - \rho_{\text{He}}}$$

The volume of the balloon is given by:

$$V_{\text{balloon}} = \tfrac{4}{3}\pi r^3 = \tfrac{1}{6}\pi d^3$$

Substituting for V_{balloon} yields:

$$\tfrac{1}{6}\pi d^3 = \frac{m_\text{p}}{\rho_\text{air} - \rho_\text{He}} \Rightarrow d = \sqrt[3]{\frac{6m_\text{p}}{\pi(\rho_\text{air} - \rho_\text{He})}}$$

Substitute numerical values and evaluate d:

$$d = \sqrt[3]{\frac{6(25.0\text{ kg})}{\pi(1.293\text{ kg/m}^3 - 0.179\text{ kg/m}^3)}} = \boxed{3.50\text{ m}}$$

19 •• Your friend wants to start a business giving hot-air balloon rides. The empty balloon, the basket and the occupants have a total maximum mass of 1000 kg. If the balloon has a diameter of 22.0 m when fully inflated with hot air, estimate the required density of the hot air. Neglect the buoyancy force on the basket and people.

Picture the Problem We can use Archimedes' principle and the condition for vertical equilibrium to estimate the density of the hot air that would enable the balloon and its payload to lift off.

Express the equilibrium condition that must be satisfied if the balloon-payload is to "just lift off":

$$F_\text{bouyant} = B = F_\text{gravitational} = mg \qquad (1)$$

Using Archimedes' principle, express the buoyant force B:

$$B = w_\text{displaced fluid} = m_\text{displaced fluid}\,g = \rho_\text{air} V_\text{balloon}\, g$$

Substituting for B in equation (1) yields:

$$\rho_\text{air} V_\text{balloon}\, g = mg \Rightarrow \rho_\text{air} V_\text{balloon} = m \qquad (2)$$

The total mass m to be lifted is the sum of the mass of the payload m_p and the mass of the hot air:

$$m = m_\text{p} + m_\text{hot air} = m_\text{p} + \rho_\text{hot air} V_\text{balloon}$$

Substitute for m in equation (2) to obtain:

$$\rho_\text{air} V_\text{balloon} = m_\text{p} + \rho_\text{hot air} V_\text{balloon}$$

Solving for $\rho_\text{hot air}$ and simplifying yields:

$$\rho_\text{hot air} = \frac{\rho_\text{air} V_\text{balloon} - m_\text{p}}{V_\text{balloon}} = \rho_\text{air} - \frac{m_\text{p}}{V_\text{balloon}}$$

The volume of the balloon is given by:

$$V_\text{balloon} = \tfrac{4}{3}\pi r^3 = \tfrac{1}{6}\pi d^3$$

Substituting for V_balloon yields:

$$\rho_\text{hot air} = \rho_\text{air} - \frac{m_\text{p}}{\tfrac{1}{6}\pi d^3} = \rho_\text{air} - \frac{6m_\text{p}}{\pi d^3}$$

Substitute numerical values and evaluate $\rho_{\text{hot air}}$:

$$\rho_{\text{hot air}} = 1.293\ \text{kg/m}^3 - \frac{6(1000\ \text{kg})}{\pi(22.0\ \text{m})^3} = \boxed{1.11\ \text{kg/m}^3}$$

Remarks: As expected, the density of the hot air is considerably less than the density of the surrounding cooler air.

Density

20 • Find the mass of a solid lead sphere with a radius equal to 2.00 cm.

Picture the Problem The mass of the sphere is the product of its density and volume. The density of lead can be found in Figure 13-1.

Using the definition of density, express the mass of the sphere:

$$m = \rho V = \rho\left(\tfrac{4}{3}\pi R^3\right)$$

Substitute numerical values and evaluate m:

$$m = \tfrac{4}{3}\pi\left(11.3\times10^3\ \text{kg/m}^3\right)\left(2.00\times10^{-2}\ \text{m}\right)^3 = \boxed{0.379\ \text{kg}}$$

21 • **[SSM]** Consider a room measuring 4.0 m × 5.0 m × 4.0 m. Under normal atmospheric conditions at Earth's surface, what would be the mass of the air in the room?

Picture the Problem The mass of the air in the room is the product of its density and volume. The density of air can be found in Figure 13-1.

Use the definition of density to express the mass of the air in the room:

$$m = \rho V = \rho LWH$$

Substitute numerical values and evaluate m:

$$m = \left(1.293\ \text{kg/m}^3\right)(4.0\ \text{m})(5.0\ \text{m})(4.0\ \text{m}) = \boxed{1.0\times10^2\ \text{kg}}$$

22 •• An average neutron star has approximately the same mass as the Sun, but is compressed into a sphere of radius roughly 10 km. What would be the approximate mass of a teaspoonful of matter that dense?

Picture the Problem We can use the definition of density to find the approximate mass of a teaspoonful of matter from a neutron star. Assume that the volume of a teaspoon is about 5 mL.

Use the definition of density to express the mass of a teaspoonful of matter whose density is ρ:

$$m = \rho V_{\text{teaspoon}} \qquad (1)$$

The density of the neutron star is given by:

$$\rho_{\text{NS}} = \frac{m_{\text{NS}}}{V_{\text{NS}}}$$

Substituting for m_{NS} and V_{NS} yields:

$$\rho_{\text{NS}} = \frac{m_{\text{Sun}}}{\frac{4}{3}\pi r_{\text{NS}}^3}$$

Let $\rho = \rho_{\text{NS}}$ in equation (1) to obtain:

$$m = \frac{3m_{\text{Sun}}V_{\text{teaspoon}}}{4\pi r_{\text{NS}}^3}$$

Substitute numerical values and evaluate m:

$$m = \frac{3\left(1.99\times10^{30}\ \text{kg}\right)\left(5\times10^{-6}\,\text{m}^3\right)}{4\pi\left(10\times10^3\ \text{m}\right)^3} \approx \boxed{2\ \text{Tg}}$$

23 •• A 50.0-g ball consists of a plastic spherical shell and a water-filled core. The shell has an outside diameter equal to 50.0 mm and an inside diameter equal to 20.0 mm. What is the density of the plastic?

Picture the Problem We can use the definition of density to find the density of the plastic of which the spherical shell is constructed.

The density of the plastic is given by:

$$\rho_{\text{plastic}} = \frac{m_{\text{plastic}}}{V_{\text{plastic}}} \qquad (1)$$

The mass of the plastic is the difference between the mass of the ball and the mass of its water-filled core:

$$m_{\text{plastic}} = m_{\text{ball}} - m_{\text{water}}$$

Use the definition of density to express the mass of the water:

$$m_{\text{water}} = \rho_{\text{water}}V_{\text{water}}$$

Substituting for m_{water} yields:

$$m_{\text{plastic}} = m_{\text{ball}} - \rho_{\text{water}}V_{\text{water}}$$

Substitute for m_{plastic} in equation (1) to obtain:

$$\rho_{\text{plastic}} = \frac{m_{\text{ball}} - \rho_{\text{water}}V_{\text{water}}}{V_{\text{plastic}}}$$

Because $V_{\text{water}} = \frac{4}{3}\pi R_{\text{inside}}^3$ and $V_{\text{ball}} = \frac{4}{3}\pi\left(R_{\text{outside}}^3 - R_{\text{inside}}^3\right)$:

$$\rho_{\text{plastic}} = \frac{m_{\text{ball}} - \rho_{\text{water}}\left(\frac{4}{3}\pi R_{\text{inside}}^3\right)}{\frac{4}{3}\pi\left(R_{\text{outside}}^3 - R_{\text{inside}}^3\right)}$$

Substitute numerical values and evaluate ρ_{plsstic}:

$$\rho_{\text{plastic}} = \frac{50.0\text{ g} - \left(1.00\,\frac{\text{g}}{\text{cm}^3}\right)\left(\frac{4}{3}\pi(10.0\text{ mm})^3\right)}{\frac{4}{3}\pi\left((25.0\text{ mm})^3 - (10.0\text{ mm})^3\right)} = \boxed{0.748\text{ g/cm}^3}$$

24 •• A 60.0-mL flask is filled with mercury at 0ºC (Figure 13-31). When the temperature rises to 80ºC, 1.47 g of mercury spills out of the flask. Assuming that the volume of the flask stays constant, find the change in density of mercury at 80ºC if its density at 0ºC is 13 645 kg/m^3.

Picture the Problem We can use the definition of density to relate the change in the density of the mercury to the amount spilled during the heating process.

The change in the density of the mercury as it is warmed is given by:

$$\Delta\rho = \rho_0 - \rho \qquad (1)$$

where ρ_0 is the density of the mercury before it is warmed.

The density of the mercury before it is warmed is the ratio of its mass to the volume it occupies:

$$\rho_0 = \frac{m_0}{V_0} \qquad (2)$$

The volume of the mercury that spills is the ratio of its mass to its density at the higher temperature:

$$V_{\text{spilled}} = \frac{m_{\text{spilled}}}{\rho}$$

The density ρ of the mercury at the higher temperature is given by:

$$\rho = \frac{m_0}{V_0 + V_{\text{spilled}}} = \frac{m_0}{V_0 + \dfrac{m_{\text{spilled}}}{\rho}}$$

Solving for ρ yields:

$$\rho = \frac{m_0 - m_{\text{spilled}}}{V_0} = \rho_0 - \frac{m_{\text{spilled}}}{V_0} \qquad (3)$$

Substituting equations (2) and (3) in equation (1) yields:

$$\Delta\rho = \rho_0 - \left(\rho_0 - \frac{m_{\text{spilled}}}{V_0}\right) = \frac{m_{\text{spilled}}}{V_0}$$

Substitute numerical values and evaluate $\Delta\rho$:

$$\Delta\rho = \frac{1.47\times10^{-3}\,\text{kg}}{60.0\times10^{-6}\,\text{m}^3} = \boxed{24.5\,\text{kg/m}^3}$$

25 •• One sphere is made of gold and has a radius r_{Au} and another sphere is made of copper and has a radius r_{Cu}. If the spheres have equal mass, what is the ratio of the radii, $r_{\text{Au}}/r_{\text{Cu}}$?

Picture the Problem We can use the definition of density to find the ratio of the radii of the two spheres. See Table 13-1 for the densities of gold and copper.

Use the definition of density to express the mass of the gold sphere:

$$m_{\text{Au}} = \rho_{\text{Au}}V_{\text{Au}} = \tfrac{4}{3}\pi\rho_{\text{Au}}r_{\text{Au}}^3$$

The mass of the copper sphere is given by:

$$m_{\text{Cu}} = \rho_{\text{Cu}}V_{\text{Cu}} = \tfrac{4}{3}\pi\rho_{\text{Cu}}r_{\text{Cu}}^3$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{m_{\text{Au}}}{m_{\text{Cu}}} = \frac{\tfrac{4}{3}\pi\rho_{\text{Au}}r_{\text{Au}}^3}{\tfrac{4}{3}\pi\rho_{\text{Cu}}r_{\text{Cu}}^3} = \frac{\rho_{\text{Au}}}{\rho_{\text{Cu}}}\left(\frac{r_{\text{Au}}}{r_{\text{Cu}}}\right)^3$$

Solve for $r_{\text{Au}}/r_{\text{Cu}}$ to obtain:

$$\frac{r_{\text{Au}}}{r_{\text{Cu}}} = \sqrt[3]{\frac{m_{\text{Au}}}{m_{\text{Cu}}}\frac{\rho_{\text{Cu}}}{\rho_{\text{Au}}}}$$

Because the spheres have the same mass:

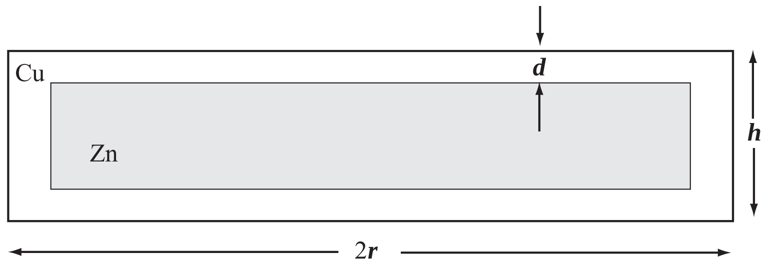
$$\frac{r_{\text{Au}}}{r_{\text{Cu}}} = \sqrt[3]{\frac{\rho_{\text{Cu}}}{\rho_{\text{Au}}}}$$

Substitute numerical values and evaluate $r_{\text{Au}}/r_{\text{Cu}}$:

$$\frac{r_{\text{Au}}}{r_{\text{Cu}}} = \sqrt[3]{\frac{8.93\,\text{kg/m}^3}{19.3\,\text{kg/m}^3}} = \boxed{0.773}$$

26 ••• Since 1983, the US Mint has coined pennies that are made out of zinc with a copper cladding. The mass of this type of penny is 2.50 g. Model the penny as a uniform cylinder of height 1.23 mm and radius 9.50 mm. Assume the copper cladding is uniformly thick on all surfaces. If the density of zinc is 7140 kg/m^3 and that of copper is 8930 kg/m^3, what is the thickness of the copper cladding?

Picture the Problem The pictorial representation shows a zinc penny with its copper cladding. We can use the definition of density to relate the difference between the mass of an all-copper penny and the mass of a copper-zinc penny to the thickness d of the copper cladding.



Express the mass 0f the cladded penny:

$$m = m_{\text{Cu}} + m_{\text{Zn}}$$

In terms of the densities of copper and zinc, our equation becomes:

$$m = \rho_{\text{Cu}} V_{\text{Cu}} + \rho_{\text{Zn}} V_{\text{Zn}}$$

Substituting for the volumes of zinc and copper gives:

$$m = \rho_{\text{Cu}}\left[2\pi r^2 d + 2\pi r(h-2d)d\right] + \rho_{\text{Zn}}\,\pi(r-d)^2(h-2d)$$

Factor h and r from $(h - 2d)$ and $(r - d)^2$ to obtain:

$$m = \rho_{\text{Cu}}\left[2\pi r^2 d + 2\pi r h\left(1-\frac{2d}{h}\right)d\right] + \rho_{\text{Zn}}\,\pi r^2\left(1-\frac{d}{r}\right)^2 h\left(1-\frac{2d}{h}\right)$$

Assuming that $d \ll h$ and $d \ll r$:

$$m \approx \rho_{\text{Cu}}\left[2\pi r^2 d + 2\pi r h d\right] + \rho_{\text{Zn}}\,\pi r^2 h$$

Solving for d yields:

$$d = \frac{m - \rho_{\text{Zn}}\pi r^2 h}{2\pi r \rho_{\text{Cu}}(r+h)}$$

Substitute numerical values and evaluate d:

$$d = \frac{2.50\times10^{-3}\ \text{kg} - \pi\left(7140\ \text{kg/m}^3\right)(9.50\ \text{mm})^2(1.23\ \text{mm})}{2\pi(9.50\ \text{mm})\left(8930\ \text{kg/m}^3\right)(9.50\ \text{mm}+1.23\ \text{mm})} \approx \boxed{1.7\ \mu\text{m}}$$

Remarks: This small value for *d* (approximately 2 μm) justifies our assumptions that *d* is much smaller than both *r* and *h*.

Pressure

27 • Barometer readings are commonly given in inches of mercury (inHg). Find the pressure in inches of mercury equal to 101 kPa.

Picture the Problem The pressure due to a column of height h of a liquid of density ρ is given by $P = \rho g h$.

Letting h represent the height of the column of mercury, express the pressure at its base:

$$\rho_{Hg}gh = 101\,\text{kPa} \Rightarrow h = \frac{101\,\text{kPa}}{\rho_{Hg}g}$$

Substitute numerical values and evaluate h:

$$h = \frac{101\,\text{kPa}}{(13.6\times10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)}$$
$$= 0.7570\,\text{m} \times \frac{1\,\text{in}}{2.54\times10^{-2}\ \text{m}}$$
$$= \boxed{29.8\ \text{inHg}}$$

28 • The pressure on the surface of a lake is P_{at} = 101 kPa. (*a*) At what depth is the pressure $2P_{at}$? (*b*) If the pressure at the top of a deep pool of mercury is P_{at}, at what depth is the pressure $2P_{at}$?

Picture the Problem The pressure due to a column of height h of a liquid of density ρ is given by $P = \rho gh$. The pressure at any depth in a liquid is the sum of the pressure at the surface of the liquid and the pressure due to the liquid at a given depth in the liquid.

(*a*) Express the pressure as a function of depth in the lake:

$$P = P_{at} + \rho_{water}gh \Rightarrow h = \frac{P - P_{at}}{\rho_{water}g}$$

Substitute for P and simplify to obtain:

$$h = \frac{2P_{at} - P_{at}}{\rho_{water}g} = \frac{P_{at}}{\rho_{water}g}$$

Substitute numerical values and evaluate h:

$$h = \frac{101\,\text{kPa}}{(1.00\times10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)}$$
$$= \boxed{10.3\,\text{m}}$$

(*b*) Proceed as in (*a*) with ρ_{water} replaced by ρ_{Hg} to obtain:

$$h = \frac{2P_{at} - P_{at}}{\rho_{Hg}g} = \frac{P_{at}}{\rho_{Hg}g}$$

Substitute numerical values and evaluate h:

$$h = \frac{101\,\text{kPa}}{(13.6\times10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)}$$
$$= \boxed{75.7\,\text{cm}}$$

29 • When at cruising altitude, a typical airplane cabin will have an air pressure equivalent to an altitude of about 2400 m. During the flight, ears often equilibrate, so that the air pressure inside the inner ear equalizes with the air

pressure outside the plane. The Eustachian tubes allow for this equalization, but can become clogged. If an Eustachian tube is clogged, pressure equalization may not occur on descent and the air pressure inside an inner ear may remain equal to the pressure at 2400 m. In that case, by the time the plane lands and the cabin is repressurized to sea-level air pressure, what is the net force on one ear drum, due to this pressure difference, assuming the ear drum has an area of 0.50 cm^2?

Picture the Problem Assuming the density of the air to be constant, we can use the definition of pressure and the expression for the variation of pressure with depth in a fluid to find the net force on one's ear drums.

The net force acting on one ear drum is given by:

$$F = \Delta PA$$

where A is the area of an ear drum.

Relate the pressure difference to the pressure at 2400 m and the pressure at sea level:

$$\Delta P = P_{\text{sea level}} - P_{2400\,\text{m}} = \rho g \Delta h$$

Substituting for ΔP in the expression for F yields:

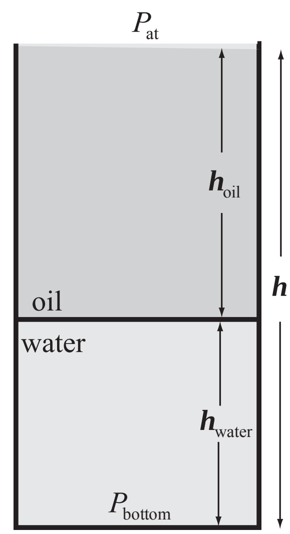
$$F = \rho\, g \Delta h A$$

Substitute numerical values and evaluate F:

$$F = \left(1.293\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)\left(2400\,\text{m}\right)\left(0.50\,\text{cm}^2\right) = \boxed{1.5\,\text{N}}$$

30 • The axis of a cylindrical container is vertical. The container is filled with equal masses of water and oil. The oil floats on top of the water, and the open surface of the oil is at a height h above the bottom of the container. What is the height h, if the pressure at the bottom of the water is 10 kPa greater than the pressure at the top of the oil? Assume the oil density is 875 kg/m^3.

Picture the Problem The pictorial representation represents oil floating on water in a cylindrical container that is open to the atmosphere. We can express the height of the cylinder as the sum of the heights of the cylinders of oil and water and then use the fact that the masses of oil and water are equal to obtain a relationship between h_{oil} and h_{water}. This relationship, together with the equation for the pressure as function of depth in a liquid will lead us to expressions for h_{oil} and h_{water}.



Express h as the sum of the heights of the cylinders of oil and water:

$$h = h_{\text{oil}} + h_{\text{water}} \tag{1}$$

The difference in pressure between the bottom of the water and the top of oil is:

$$\Delta P = P_{\text{bottom}} - P_{\text{at}} = \frac{m_{\text{water}}g + m_{\text{oil}}g}{A}$$

where A is the cross-sectional area of the cylinder.

Substituting for m_{water} and m_{oil} and simplifying gives:

$$\frac{\Delta P}{g} = \rho_{\text{water}}h_{\text{water}} + \rho_{\text{oil}}h_{\text{oil}} \tag{2}$$

Because the masses of oil and water are equal:

$$\frac{m_{\text{water}}}{m_{\text{oil}}} = \frac{\rho_{\text{water}}h_{\text{water}}A}{\rho_{\text{oil}}h_{\text{oil}}A} = \frac{\rho_{\text{water}}h_{\text{water}}}{\rho_{\text{oil}}h_{\text{oil}}} = 1$$

and

$$\rho_{\text{water}}h_{\text{water}} = \rho_{\text{oil}}h_{\text{oil}}$$

Substituting for $\rho_{\text{oil}}h_{\text{oil}}$ in equation (2) yields:

$$\frac{\Delta P}{g} = \rho_{\text{water}}h_{\text{water}} + \rho_{\text{water}}h_{\text{water}}$$

$$= 2\rho_{\text{water}}h_{\text{water}}$$

and

$$h_{\text{water}} = \frac{\Delta P}{2\rho_{\text{water}}g}$$

Proceed similarly to obtain:

$$h_{\text{oil}} = \frac{\Delta P}{2\rho_{\text{oil}}g}$$

Substituting for h_{water} and h_{oil} in equation (1) gives:

$$h = \frac{\Delta P}{2\rho_{\text{oil}}g} + \frac{\Delta P}{2\rho_{\text{water}}g} = \frac{\Delta P}{2g}\left(\frac{1}{\rho_{\text{oil}}} + \frac{1}{\rho_{\text{water}}}\right)$$

Substitute numerical values and evaluate h:

$$h = \frac{10\text{ kPa}}{2(9.81\text{ m/s}^2)}\left(\frac{1}{875\text{ kg/m}^3} + \frac{1}{1.00\times10^3\text{ kg/m}^3}\right) = \boxed{1.1\text{ m}}$$

31 • [SSM] A hydraulic lift is used to raise a 1500-kg automobile. The radius of the shaft of the lift is 8.00 cm and the radius of the compressor's piston is 1.00 cm. How much force must be applied to the piston to raise the automobile? *Hint*: *The shaft of the lift is the other piston.*

Picture the Problem The pressure applied to an enclosed liquid is transmitted undiminished to every point in the fluid and to the walls of the container. Hence we can equate the pressure produced by the force applied to the piston to the pressure due to the weight of the automobile and solve for F.

Express the pressure the weight of the automobile exerts on the shaft of the lift:

$$P_{\text{auto}} = \frac{w_{\text{auto}}}{A_{\text{shaft}}}$$

Express the pressure the force applied to the piston produces:

$$P = \frac{F}{A_{\text{piston}}}$$

Because the pressures are the same, we can equate them to obtain:

$$\frac{w_{\text{auto}}}{A_{\text{shaft}}} = \frac{F}{A_{\text{piston}}}$$

Solving for F yields:

$$F = w_{\text{auto}}\frac{A_{\text{piston}}}{A_{\text{shaft}}} = m_{\text{auto}}g\frac{A_{\text{piston}}}{A_{\text{shaft}}}$$

Substitute numerical values and evaluate F:

$$F = (1500\text{ kg})(9.81\text{ m/s}^2)\left(\frac{1.00\text{ cm}}{8.00\text{ cm}}\right)^2 = \boxed{230\text{ N}}$$

32 • A 1500-kg car rests on four tires, each of which is inflated to a gauge pressure of 200 kPa. If the four tires support the car's weight equally, what is the area of contact of each tire with the road?

Picture the Problem The area of contact of each tire with the road is related to the weight on each tire and the pressure in the tire through the definition of pressure.

Using the definition of gauge pressure, relate the area of contact to the pressure and the weight of the car:

$$A = \frac{\frac{1}{4}w}{P_{\text{gauge}}} = \frac{mg}{4P_{\text{gauge}}}$$

Substitute numerical values and evaluate A:

$$A = \frac{(1500\,\text{kg})(9.81\,\text{m/s}^2)}{4(200\,\text{kPa})} = \boxed{184\,\text{cm}^2}$$

33 •• What pressure increase is required to compress the volume of 1.00 kg of water from 1.00 L to 0.99 L? Could this compression occur in our oceans where the maximum depth is about 11 km? Explain.

Picture the Problem The required pressure ΔP is related to the change in volume ΔV and the initial volume V through the definition of the bulk modulus B; $B = -\dfrac{\Delta P}{\Delta V/V}$.

Using the definition of the bulk modulus, relate the change in volume to the initial volume and the required pressure:

$$B = -\frac{\Delta P}{\Delta V/V} \Rightarrow \Delta P = -B\frac{\Delta V}{V}$$

Substitute numerical values and evaluate ΔP:

$$\Delta P = -2.00\times10^{9}\ \text{Pa}\times\left(\frac{-0.01\,\text{L}}{1.00\,\text{L}}\right)$$

$$= 2.00\times10^{7}\ \text{Pa}\times\frac{1\,\text{atm}}{101.325\,\text{kPa}}$$

$$= 197.4\ \text{atm} = \boxed{197\,\text{atm}}$$

Express the pressure at a depth h in the ocean:

$$P(h) = P_{\text{at}} + \rho_{\text{seawater}}gh$$

or

$$\Delta P = \rho_{\text{seawater}}gh \Rightarrow h = \frac{\Delta P}{\rho_{\text{seawater}}g}$$

Substitute numerical values and evaluate h:

$$h = \frac{197.4\,\text{atm} \times \dfrac{101.325\,\text{kPa}}{\text{atm}}}{\left(1025\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)} \approx 2.0\,\text{km}$$

Because a depth of only 2 km is required to produce a one-percent compression, this does not occur in our oceans.

34 •• When a woman in high-heeled shoes takes a step, she momentarily places her entire weight on one heel of her shoe. If her mass is 56.0 kg and if the area of the heel is 1.00 cm^2, what is the pressure exerted on the floor by the heel? Compare your answer to the pressure exerted by the one foot of an elephant on a flat floor. Assume the elephant's mass is 5000 kg, that he has all four feet equally distributed on the floor, and that each foot has an area of 400 cm^2.

Picture the Problem The pressure exerted by the woman's heel on the floor is her weight divided by the area of her heel.

Using its definition, express the pressure exerted on the floor by the woman's heel:

$$P = \frac{F}{A} = \frac{w}{A} = \frac{mg}{A}$$

Substitute numerical values and evaluate P_{woman}:

$$P_{\text{woman}} = \frac{(56.0\,\text{kg})\left(9.81\,\text{m/s}^2\right)}{1.00 \times 10^{-4}\,\text{m}^2}$$

$$= 5.49 \times 10^6\ \text{N/m}^2 \times \frac{1\,\text{atm}}{101.325\,\text{kPa}}$$

$$= \boxed{54.2\,\text{atm}}$$

Express the pressure exerted by one of the elephant's feet:

$$P_{\text{elephant}} = \frac{\frac{1}{4}(5000\,\text{kg})\left(9.81\,\text{m/s}^2\right)}{400 \times 10^{-4}\,\text{m}^2} = 3.066 \times 10^5\ \text{N/m}^2 \times \frac{1\,\text{atm}}{101.325\,\text{kPa}} = 3.03\,\text{atm}$$

Express the ratio of the pressure exerted by the woman's heel to the pressure exerted by the elephant's foot:

$$\frac{P_{\text{woman}}}{P_{\text{elephant}}} = \frac{54.2\,\text{atm}}{3.03\,\text{atm}} \approx 18$$

Thus $P_{\text{woman}} \approx \boxed{18 P_{\text{elephant}}}.$

35 •• In the seventeenth century, Blaise Pascal performed the experiment shown in Figure 13-32. A wine barrel filled with water was coupled to a long tube. Water was added to the tube until the barrel burst. The radius of the lid was 20 cm and the height of the water in the tube was 12 m. (*a*) Calculate the force exerted on the lid due to the pressure increase. (*b*) If the tube had an inner radius

of 3.0 mm, what mass of water in the tube caused the pressure that burst the barrel?

Picture the Problem The force on the lid is related to pressure exerted by the water and the cross-sectional area of the column of water through the definition of density. We can find the mass of the water from the product of its density and volume.

(*a*) Using the definition of pressure, express the force exerted on the lid:

$$F = PA$$

Express the pressure due to a column of water of height *h*:

$$P = \rho_{\text{water}} gh$$

Substitute for *P* and *A* to obtain:

$$F = \rho_{\text{water}} gh\pi r^2$$

Substitute numerical values and evaluate *F*:

$$F = \left(1.00\times10^3\ \text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)\times\left(12\,\text{m}\right)\pi\left(0.20\,\text{m}\right)^2 = \boxed{15\,\text{kN}}$$

(*b*) Relate the mass of the water to its density and volume:

$$m = \rho_{\text{water}} V = \rho_{\text{water}} h\pi r^2$$

Substitute numerical values and evaluate *m*:

$$m = \left(1.00\times10^3\ \text{kg/m}^3\right)\left(12\,\text{m}\right)\pi\left(3.0\times10^{-3}\ \text{m}\right)^2 = \boxed{0.34\,\text{kg}}$$

36 •• Blood plasma flows from a bag through a tube into a patient's vein, where the blood pressure is 12 mmHg. The specific gravity of blood plasma at 37ºC is 1.03. What is the minimum elevation of the bag so that the plasma flows into the vein?

Picture the Problem The minimum elevation of the bag *h* that will produce a pressure of at least 12 mmHg is related to this pressure and the density of the blood plasma through $P = \rho_{\text{blood}} gh$.

Using the definition of the pressure due to a column of liquid, relate the pressure at its base to its height:

$$P = \rho_{\text{blood}} gh \Rightarrow h = \frac{P}{\rho_{\text{blood}} g}$$

Substitute numerical values and evaluate h:

$$h = \frac{12\,\text{mmHg} \times \dfrac{133.32\,\text{Pa}}{1\,\text{mmHg}}}{\left(1.03\times10^3\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)} = \boxed{16\,\text{cm}}$$

37 •• Many people have imagined that if they were to float the top of a flexible snorkel tube out of the water, they would be able to breathe through it while walking underwater (Figure 13-33). However, they generally do not take into account just how much water pressure opposes the expansion of the chest and the inflation of the lungs. Suppose you can just breathe while lying on the floor with a 400-N (90-lb) weight on your chest. How far below the surface of the water could your chest be for you still to be able to breathe, assuming your chest has a frontal area of 0.090 m^2?

Picture the Problem The depth h below the surface at which you would be able to breath is related to the pressure at that depth and the density of water ρ_w through $P = \rho_w gh$.

Express the pressure due to a column of water of height h:

$$P = \rho_w gh \Rightarrow h = \frac{P}{\rho_w g}$$

Express the pressure at depth h in terms of the weight on your chest:

$$P = \frac{w_{\text{on your chest}}}{A_{\text{of your chest}}}$$

Substituting for P yields:

$$h = \frac{w_{\text{on your chest}}}{A_{\text{of your chest}}\rho_w g}$$

Substitute numerical values and evaluate h:

$$h = \frac{400\,\text{N}}{\left(0.090\,\text{m}^2\right)\left(1.00\times10^3\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)} = \boxed{45\,\text{cm}}$$

38 •• In Example 13-3 a 150-N force is applied to a small piston to lift a car that weighs 15 000 N. Demonstrate that this does not violate the law of conservation of energy by showing that, when the car is lifted some distance h, the work done by the 150-N force acting on the small piston equals the work done on the car by the large piston.

Picture the Problem Let A_1 and A_2 represent the cross-sectional areas of the large piston and the small piston, and F_1 and F_2 the forces exerted by the large and on the small piston, respectively. The work done by the large piston is $W_1 = F_1h_1$ and

that done on the small piston is $W_2 = F_2h_2$. We'll use Pascal's principle and the equality of the volume of the displaced liquid in both pistons to show that W_1 and W_2 are equal.

Express the work done in lifting the car a distance h:

$$W_1 = F_1h_1$$

where F_1 is the weight of the car.

Using the definition of pressure, relate the forces F_1 (= w) and F_2 to the areas A_1 and A_2:

$$\frac{F_1}{A_1} = \frac{F_2}{A_2} \Rightarrow F_1 = F_2\frac{A_1}{A_2}$$

Equate the volumes of the displaced fluid in the two pistons:

$$h_1A_1 = h_2A_2 \Rightarrow h_1 = h_2\frac{A_2}{A_1}$$

Substitute in the expression for W_1 and simplify to obtain:

$$W_1 = F_2\frac{A_1}{A_2}h_2\frac{A_2}{A_1} = F_2h_2 = \boxed{W_2}$$

39 •• A 5.00-kg lead sinker is accidentally dropped overboard by fishermen in a boat directly above the deepest portion of the Marianas trench, near the Philippines. By what percentage does the volume of the sinker change by the time it settles to the trench bottom, which is 10.9 km below the surface?

Picture the Problem This problem is an application of the definition of the bulk modulus. The change in volume of the sinker is related to the pressure change and the bulk modulus by $B = -\frac{\Delta P}{\Delta V/V}$.

From the definition of bulk modulus:

$$\frac{\Delta V}{V} = -\frac{\Delta P}{B} \qquad (1)$$

Express the pressure at a depth h in the ocean:

$$P(h) = P_{at} + \rho gh$$

The difference in pressure between the pressure at depth h and the surface of the water is:

$$\Delta P = P(h) - P_{at} = \rho gh$$

Substitute for ΔP in equation (1) to obtain:

$$\frac{\Delta V}{V} = -\frac{\rho gh}{B}$$

Substitute numerical values and evaluate the fractional change in volume of the sinker:

$$\frac{\Delta V}{V}=-\frac{(1025\ \text{kg/m}^3)(9.81\ \text{m/s}^2)(10.9\ \text{km})}{7.7\ \text{GPa}}=\boxed{-1.4\%}$$

40 ••• The volume of a cone of height h and base radius r is $V = \pi r^2h/3$. A jar in the shape of a cone of height 25 cm has a base with a radius equal to 15 cm. The jar is filled with water. Then its lid (the base of the cone) is screwed on and the jar is turned over so its lid is horizontal. (*a*) Find the volume and weight of the water in the jar. (*b*) Assuming the pressure inside the jar at the top of the cone is equal to 1 atm, find the excess force exerted by the water on the base of the jar. Explain how this force can be greater than the weight of the water in the jar.

Picture the Problem The weight of the water in the jar is the product of its mass and the gravitational field. Its mass, in turn, is related to its volume through the definition of density. The force the water exerts on the base of the jar can be determined from the product of the pressure it creates and the area of the base.

(*a*) The volume of the water is:

$$V=\tfrac{1}{3}\pi\left(15\times10^{-2}\ \text{m}\right)^2\left(25\times10^{-2}\ \text{m}\right)=5.890\times10^{-3}\ \text{m}^3=\boxed{5.9\ \text{L}}$$

Using the definition of density, relate the weight of the water to the volume it occupies:

$$w=mg=\rho Vg$$

$$w=\left(1.00\times10^3\ \frac{\text{kg}}{\text{m}^3}\right)\left(5.890\times10^{-3}\ \text{m}^3\right)\left(9.81\ \frac{\text{m}}{\text{s}^2}\right)=57.79\ \text{N}=\boxed{58\ \text{N}}$$

(*b*) Using the definition of pressure, relate the force exerted by the water on the base of the jar to the pressure it exerts and the area of the base:

$$F=PA=\rho gh\pi r^2$$

Substitute numerical values and evaluate F:

$$F=\left(1.00\times10^3\ \text{kg/m}^3\right)\left(9.81\text{m/s}^2\right)\left(25\times10^{-2}\ \text{m}\right)\pi\left(15\times10^{-2}\ \text{m}\right)^2=\boxed{0.17\text{kN}}$$

This occurs in the same way that the force on Pascal's barrel is much greater than the weight of the water in the tube. The downward force on the base is also the result of the downward component of the force exerted by the slanting walls of the cone on the water.

Buoyancy

41 • A 500-g piece of copper with specific gravity 8.96, is suspended from a spring scale and is submerged in water (Figure 13-34). What force does the spring scale read?

Picture the Problem The scale's reading is the difference between the weight of the piece of copper in air and the buoyant force acting on it.

Express the apparent weight w' of the piece of copper:

$$w' = w - B$$

Using the definition of density and Archimedes' principle, substitute for w and B to obtain:

$$w' = \rho_{\text{Cu}}Vg - \rho_{\text{w}}Vg = (\rho_{\text{Cu}} - \rho_{\text{w}})Vg$$

Express w in terms of ρ_{Cu} and V and solve for Vg:

$$w = \rho_{\text{Cu}}Vg \Rightarrow Vg = \frac{w}{\rho_{\text{Cu}}}$$

Substitute for Vg in the expression for w' to obtain:

$$w' = (\rho_{\text{Cu}} - \rho_{\text{w}})\frac{w}{\rho_{\text{Cu}}} = \left(1 - \frac{\rho_{\text{w}}}{\rho_{\text{Cu}}}\right)w$$

Substitute numerical values and evaluate w':

$$w' = \left(1 - \frac{1}{8.96}\right)(0.500\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{4.36\,\text{N}}$$

42 • When a certain rock is suspended from a spring scale the scale-display reads 60 N. However, when the suspended rock is submerged in water, the display reads 40 N. What is the density of the rock?

Picture the Problem We can use the definition of density and Archimedes' principle to find the density of the rock. The difference between the weight of the rock in air and the weight of the rock in water is the buoyant force acting on the rock.

Using its definition, express the density of the rock:

$$\rho_{\text{rock}} = \frac{m_{\text{rock}}}{V_{\text{rock}}} \qquad (1)$$

Apply Archimedes' principle to obtain:

$$B = w_{\substack{\text{displaced}\\\text{fluid}}} = m_{\substack{\text{displaced}\\\text{fluid}}} g = \rho_{\substack{\text{displaced}\\\text{fluid}}} V_{\substack{\text{displaced}\\\text{fluid}}} g$$

Solve for $V_{\substack{\text{displaced}\\\text{fluid}}}$:

$$V_{\substack{\text{displaced}\\\text{fluid}}} = \frac{B}{\rho_{\substack{\text{displaced}\\\text{fluid}}} g}$$

Because $V_{\substack{\text{displaced}\\\text{fluid}}} = V_{\text{rock}}$ and $\rho_{\substack{\text{displaced}\\\text{fluid}}} = \rho_{\text{water}}$:

$$V_{\text{rock}} = \frac{B}{\rho_{\text{water}} g}$$

Substituting in equation (1) and simplifying yields:

$$\rho_{\text{rock}} = \frac{m_{\text{rock}} g}{B} \rho_{\text{water}} = \frac{w_{\text{rock}}}{B} \rho_{\text{water}}$$

Substitute numerical values and evaluate ρ_{rock}:

$$\rho_{\text{rock}} = \frac{60\,\text{N}}{60\,\text{N} - 40\,\text{N}} \left(1.00 \times 10^3\ \text{kg/m}^3\right) = \boxed{3.0 \times 10^3\ \text{kg/m}^3}$$

43 • **[SSM]** A block of an unknown material weighs 5.00 N in air and 4.55 N when submerged in water. (*a*) What is the density of the material? (*b*) From what material is the block likely to have been made?

Picture the Problem We can use the definition of density and Archimedes' principle to find the density of the unknown object. The difference between the weight of the object in air and in water is the buoyant force acting on the object.

(*a*) Using its definition, express the density of the object:

$$\rho_{\text{object}} = \frac{m_{\text{object}}}{V_{\text{object}}} \qquad (1)$$

Apply Archimedes' principle to obtain:

$$B = w_{\substack{\text{displaced}\\\text{fluid}}} = m_{\substack{\text{displaced}\\\text{fluid}}} g = \rho_{\substack{\text{displaced}\\\text{fluid}}} V_{\substack{\text{displaced}\\\text{fluid}}} g$$

Solve for $V_{\substack{\text{displaced}\\\text{fluid}}}$:

$$V_{\substack{\text{displaced}\\\text{fluid}}} = \frac{B}{\rho_{\substack{\text{displaced}\\\text{fluid}}} g}$$

Because $V_{\substack{\text{displaced}\\ \text{fluid}}} = V_{\text{object}}$ and $\rho_{\substack{\text{displaced}\\ \text{fluid}}} = \rho_{\text{water}}$:

$$V_{\text{object}} = \frac{B}{\rho_{\text{water}} g}$$

Substitute in equation (1) and simplify to obtain:

$$\rho_{\text{object}} = \frac{m_{\text{object}} g}{B}\rho_{\text{water}} = \frac{w_{\text{object}}}{B}\rho_{\text{water}}$$

Substitute numerical values and evaluate ρ_{object}:

$$\rho_{\text{object}} = \frac{5.00\,\text{N}}{5.00\,\text{N} - 4.55\,\text{N}}\left(1.00\times10^3\ \text{kg/m}^3\right) = \boxed{11\times10^3\ \text{kg/m}^3}$$

(*b*) From Table 13-1, we see that the density of the unknown material is close to that of lead.

44 • A solid piece of metal weighs 90.0 N in air and 56.6 N when submerged in water. Determine the density of this metal.

Picture the Problem We can use the definition of density and Archimedes' principle to find the density of the unknown object. The difference between the weight of the object in air and the weight of the object in water is the buoyant force acting on the object.

Using its definition, express the density of the metal:

$$\rho_{\text{metal}} = \frac{m_{\text{metal}}}{V_{\text{metal}}} \qquad (1)$$

Apply Archimedes' principle to obtain:

$$B = w_{\substack{\text{displaced}\\ \text{fluid}}} = m_{\substack{\text{displaced}\\ \text{fluid}}} g = \rho_{\substack{\text{displaced}\\ \text{fluid}}} V_{\substack{\text{displaced}\\ \text{fluid}}} g$$

Solve for $V_{\substack{\text{displaced}\\ \text{fluid}}}$:

$$V_{\substack{\text{displaced}\\ \text{fluid}}} = \frac{B}{\rho_{\substack{\text{displaced}\\ \text{fluid}}} g}$$

Because $V_{\substack{\text{displaced}\\ \text{fluid}}} = V_{\text{metal}}$ and $\rho_{\substack{\text{displaced}\\ \text{fluid}}} = \rho_{\text{water}}$:

$$V_{\text{metal}} = \frac{B}{\rho_{\text{water}} g}$$

Substitute in equation (1) and simplify to obtain:

$$\rho_{\text{metal}} = \frac{m_{\text{metal}} g}{B}\rho_{\text{water}} = \frac{w_{\text{metal}}}{B}\rho_{\text{water}}$$

Substitute numerical values and evaluate ρ_{metal}:

$$\rho_{\text{metal}} = \frac{90.0\,\text{N}}{90.0\,\text{N} - 56.6\,\text{N}}\left(1.00\times10^3\ \text{kg/m}^3\right) = \boxed{2.69\times10^3\ \text{kg/m}^3}$$

45 •• A homogeneous solid object floats on water, with 80.0 percent of its volume below the surface. When placed in a second liquid, the same object floats on that liquid with 72.0 percent of its volume below the surface. Determine the density of the object and the specific gravity of the liquid.

Picture the Problem Let V be the volume of the object and V' be the volume that is submerged when it floats. The weight of the object is ρVg and the buoyant force due to the water is $\rho_w V'g$. Because the floating object is in translational equilibrium, we can use $\sum F_y = 0$ to relate the buoyant forces acting on the object in the two liquids to its weight.

Apply $\sum F_y = 0$ to the object floating in water:

$$\rho_w V'g - mg = \rho_w V'g - \rho Vg = 0 \quad (1)$$

Solving for ρ yields:

$$\rho = \rho_w \frac{V'}{V}$$

Substitute numerical values and evaluate ρ:

$$\rho = \left(1.00\times10^3\ \text{kg/m}^3\right)\frac{0.800V}{V} = \boxed{800\,\text{kg/m}^3}$$

Apply $\sum F_y = 0$ to the object floating in the second liquid and solve for mg:

$$mg = 0.720\,V\rho_L g$$

Solve equation (1) for mg:

$$mg = 0.800\,\rho_w Vg$$

Equate these two expressions to obtain:

$$0.720\,\rho_L = 0.800\,\rho_w$$

Substitute in the definition of specific gravity to obtain:

$$\text{specific gravity} = \frac{\rho_L}{\rho_w} = \frac{0.800}{0.720} = \boxed{1.11}$$

46 •• A 5.00-kg iron block is suspended from a spring scale and is submerged in a fluid of unknown density. The spring scale reads 6.16 N. What is the density of the fluid?

Picture the Problem We can use Archimedes' principle to find the density of the unknown fluid. The difference between the weight of the block in air and the weight of the block in the fluid is the buoyant force acting on the block.

Apply Archimedes' principle to obtain:

$$B = w_{\substack{\text{displaced}\\\text{fluid}}} = m_{\substack{\text{displaced}\\\text{fluid}}} g = \rho_{\substack{\text{displaced}\\\text{fluid}}} V_{\substack{\text{displaced}\\\text{fluid}}} g$$

Solve for $\rho_{\substack{\text{displaced}\\\text{fluid}}}$:

$$\rho_{\substack{\text{displaced}\\\text{fluid}}} = \frac{B}{V_{\substack{\text{displaced}\\\text{fluid}}} g}$$

Because $V_{\substack{\text{displaced}\\\text{fluid}}} = V_{\text{Fe block}}$:

$$\rho_{\text{f}} = \frac{B}{V_{\text{Fe block}} g} = \frac{B}{m_{\text{Fe block}} g} \rho_{\text{Fe}}$$

Substitute numerical values and evaluate ρ_{f}:

$$\rho_{\text{f}} = \frac{(5.00\,\text{kg})(9.81\,\text{m/s}^2) - 6.16\,\text{N}}{(5.00\,\text{kg})(9.81\,\text{m/s}^2)}(7.96\times10^3\,\text{kg/m}^3) = \boxed{7.0\times10^3\,\text{kg/m}^3}$$

47 •• A large piece of cork weighs 0.285 N in air. When held submerged underwater by a spring scale as shown in Figure 13-35, the spring scale reads 0.855 N. Find the density of the cork.

Picture the Problem The forces acting on the cork are B, the upward force due to the displacement of water, mg, the weight of the piece of cork, and F_s, the force exerted by the spring. The piece of cork is in equilibrium under the influence of these forces.

Apply $\sum F_y = 0$ to the piece of cork:

$$B - w - F_s = 0 \quad (1)$$

or

$$B - \rho_{\text{cork}} Vg - F_s = 0 \quad (2)$$

Express the buoyant force as a function of the density of water:

$$B = w_{\substack{\text{displaced}\\\text{fluid}}} = \rho_{\text{w}} Vg \Rightarrow Vg = \frac{B}{\rho_{\text{w}}}$$

Substitute for Vg in equation (2) to obtain:

$$B - \rho_{\text{cork}} \frac{B}{\rho_{\text{w}}} - F_s = 0 \quad (3)$$

Solve equation (1) for B:

$$B = w + F_s$$

Substitute in equation (3) to obtain:

$$w+F_s-\rho_{cork}\frac{w+F_s}{\rho_w}-F_s=0$$

or

$$w-\rho_{cork}\frac{w+F_s}{\rho_w}=0$$

Solving for ρ_{cork} yields:

$$\rho_{cork}=\rho_w\frac{w}{w+F_s}$$

Substitute numerical values and evaluate ρ_{cork}:

$$\rho_{cork}=\left(1.00\times10^3\ \text{kg/m}^3\right)\frac{0.285\,\text{N}}{0.285\,\text{N}+0.855\,\text{N}}=\boxed{250\,\text{kg/m}^3}$$

48 •• A helium balloon lifts a basket and cargo of total weight 2000 N under standard conditions, at which the density of air is 1.29 kg/m^3 and the density of helium is 0.178 kg/m^3. What is the minimum volume of the balloon?

Picture the Problem Under minimum-volume conditions, the balloon will be in equilibrium. Let B represent the buoyant force acting on the balloon, w_{tot} represent its total weight, and V its volume. The total weight is the sum of the weights of its basket, cargo, and helium in its balloon.

Apply $\sum F_y=0$ to the balloon:

$$B-w_{tot}=0$$

Express the total weight of the balloon:

$$w_{tot}=2000\,\text{N}+\rho_{He}Vg$$

Express the buoyant force due to the displaced air:

$$B=w_{\substack{\text{displaced}\\\text{fluid}}}=\rho_{air}Vg$$

Substitute for B and w_{tot} to obtain:

$$\rho_{air}Vg-2000\,\text{N}-\rho_{He}Vg=0$$

Solving for V yields:

$$V=\frac{2000\,\text{N}}{\left(\rho_{air}-\rho_{He}\right)g}$$

Substitute numerical values and evaluate V:

$$V=\frac{2000\,\text{N}}{\left(1.29\,\text{kg/m}^3-0.178\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)}=\boxed{183\,\text{m}^3}$$

49 •• **[SSM]** An object has ″neutral buoyancy″ when its density equals that of the liquid in which it is submerged, which means that it neither floats nor sinks. If the average density of an 85-kg diver is 0.96 kg/L, what mass of lead should the dive master suggest be added to give the diver neutral buoyancy?

Picture the Problem Let V = volume of diver, ρ_D the density of the diver, V_{Pb} the volume of added lead, and m_{Pb} the mass of lead. The diver is in equilibrium under the influence of his weight, the weight of the lead, and the buoyant force of the water.

Apply $\sum F_y = 0$ to the diver:

$$B - w_D - w_{Pb} = 0$$

Substitute to obtain:

$$\rho_w V_{D+Pb} g - \rho_D V_D g - m_{Pb} g = 0$$

or

$$\rho_w V_D + \rho_w V_{Pb} - \rho_D V_D - m_{Pb} = 0$$

Rewrite this expression in terms of masses and densities:

$$\rho_w \frac{m_D}{\rho_D} + \rho_w \frac{m_{Pb}}{\rho_{Pb}} - \rho_D \frac{m_D}{\rho_D} - m_{Pb} = 0$$

Solving for m_{Pb} yields:

$$m_{Pb} = \frac{\rho_{Pb}(\rho_w - \rho_D) m_D}{\rho_D(\rho_{Pb} - \rho_w)}$$

Substitute numerical values and evaluate m_{Pb}:

$$m_{Pb} = \frac{(11.3\times10^3\ \text{kg/m}^3)(1.00\times10^3\ \text{kg/m}^3 - 0.96\times10^3\ \text{kg/m}^3)(85\,\text{kg})}{(0.96\times10^3\ \text{kg/m}^3)(11.3\times10^3\ \text{kg/m}^3 - 1.00\times10^3\ \text{kg/m}^3)} = \boxed{3.9\,\text{kg}}$$

50 •• A 1.00-kg beaker containing 2.00 kg of water rests on a scale. A 2.00-kg block of aluminum (density 2.70×10^3 kg/m^3) suspended from a spring scale is submerged in the water, as in Figure 13-36. Find the readings of both scales.

Picture the Problem The hanging scale's reading w' is the difference between the weight of the aluminum block in air w and the buoyant force acting on it. The buoyant force is equal to the weight of the displaced fluid, which, in turn, is the product of its density and mass. We can apply a condition for equilibrium to relate the reading of the bottom scale to the weight of the beaker and its contents and the buoyant force acting on the block.

Express the apparent weight w' of the aluminum block. This apparent weight is the reading on the hanging scale and is equal to the tension in the string:

$$w' = w - B \quad (1)$$

Letting F_s be the reading of the bottom scale and choosing upward to be the $+y$ direction, apply $\sum F_y = 0$ to the system consisting of the beaker and the water to obtain:

$$F_s - (M_b + M_w)g - B = 0$$

or

$$F_s = (M_b + M_w)g + B = (M_b + M_w)g + w - w' \quad (2)$$

Using Archimedes' principle, substitute for B in equation (1) to obtain:

$$w' = w - \rho_w Vg \quad (3)$$

Express w in terms of ρ_{Al} and V and solve for Vg:

$$w = \rho_{Al} Vg \Rightarrow Vg = \frac{w}{\rho_{Al}}$$

Substitute for Vg in equation (3) and simplify to obtain:

$$w' = w - \rho_w \frac{w}{\rho_{Al}} = \left(1 - \frac{\rho_w}{\rho_{Al}}\right) w$$

Substitute numerical values and evaluate w':

$$w' = \left(1 - \frac{1.00\times10^3 \text{ kg/m}^3}{2.70\times10^3 \text{ kg/m}^3}\right)(2.00\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{12.4\,\text{N}}$$

Substitute numerical values in equation (2) and evaluate F_s:

$$F_s = (1.00\text{ kg} + 2.00\text{ kg})(9.81\text{ m/s}^2) + (2.00\text{ kg})(9.81\text{ m/s}^2) - 12.4\text{ N} = \boxed{36.7\text{ N}}$$

51 •• When cracks form at the base of a dam, the water seeping into the cracks exerts a buoyant force that tends to lift the dam. As a result, the dam can topple. Estimate the buoyant force exerted on a 2.0-m thick by 5.0-m wide dam wall by water seeping into cracks at its base. The water level in the lake is 5.0 m above the cracks.

Picture the Problem We can apply Archimedes' principle to estimate the buoyant force exerted by the water on the dam. We can determine whether the buoyant force is likely to lift the dam by comparing the buoyant and gravitational forces acting on the dam.

The buoyant force acting on the dam is given by Archimedes' principle:

$$B = w_{\substack{\text{displaced}\\\text{water}}} = m_{\substack{\text{displaced}\\\text{water}}} g = \rho_{\text{water}} V_{\substack{\text{displaced}\\\text{water}}} g$$

The volume of the displaced water is the same as the volume of the dam:

$$B = \rho_{\text{water}} V_{\text{dam}} g = \rho_{\text{water}} LWHg$$

where *L, W,* and *H* are the length and width of the dam, and *H* is the height of the water above the cracks.

Substitute numerical values and evaluate *B*:

$$B = \left(1.00\times10^3\ \text{kg/m}^3\right)(2.0\ \text{m})(5.0\ \text{m})(5.0\ \text{m})\left(9.81\,\text{m/s}^2\right) = \boxed{4.9\times10^5\ \text{N}}$$

52 •• Your team is in charge of launching a large helium weather balloon that is spherical in shape, and whose radius is 2.5 m and total mass is 15 kg (balloon plus helium plus equipment). (*a*) What is the initial upward acceleration of the balloon when it is released from sea level? (*b*) If the drag force on the balloon is given by $F_{\text{D}} = \frac{1}{2}\pi r^2 \rho v^2$, where *r* is the balloon radius, ρ is the density of air, and *v* the balloon's ascension speed, calculate the terminal speed of the ascending balloon.

Picture the Problem The forces acting on the balloon are the buoyant force *B*, its weight *mg*, and a drag force F_{D}. We can find the initial upward acceleration of the balloon by applying Newton's second law at the instant it is released. We can find the terminal speed of the balloon by recognizing that when $a_y = 0$, the net force acting on the balloon will be zero.

(*a*) Apply $\sum F_y = ma_y$ to the balloon at the instant of its release to obtain:

$$B - m_{\text{balloon}} g = m_{\text{balloon}} a_y \qquad (1)$$

Using Archimedes principle, express the buoyant force B acting on the balloon:

$$\begin{aligned} B &= w_{\substack{\text{displaced}\\ \text{fluid}}} = m_{\substack{\text{displaced}\\ \text{fluid}}} g \\ &= \rho_{\substack{\text{displaced}\\ \text{fluid}}} V_{\substack{\text{displaced}\\ \text{fluid}}} g \\ &= \rho_{\text{air}} V_{\text{balloon}} g = \tfrac{4}{3}\pi\rho_{\text{air}} r^3 g \end{aligned}$$

Substitute in equation (1) to obtain:

$$\tfrac{4}{3}\pi\rho_{\text{air}} r^3 g - m_{\text{balloon}} g = m_{\text{balloon}} a_y$$

Solving for a_y yields:

$$a_y = \left(\frac{\tfrac{4}{3}\pi\rho_{\text{air}} r^3}{m_{\text{balloon}}} - 1\right) g$$

Substitute numerical values and evaluate a_y:

$$a_y = \left[\frac{\tfrac{4}{3}\pi\left(1.29\,\text{kg/m}^3\right)\left(2.5\,\text{m}\right)^3}{15\,\text{kg}} - 1\right]\left(9.81\,\text{m/s}^2\right) = \boxed{45\,\text{m/s}^2}$$

(*b*) Apply $\sum F_y = ma_y$ to the balloon under terminal-speed conditions to obtain:

$$B - mg - \tfrac{1}{2}\pi r^2 \rho v_t^2 = 0$$

Substitute for B:

$$\tfrac{4}{3}\pi\rho_{\text{air}} r^3 g - mg - \tfrac{1}{2}\pi r^2 \rho v_t^2 = 0$$

Solving for v_t yields:

$$v_t = \sqrt{\frac{2\left(\tfrac{4}{3}\pi\rho_{\text{air}} r^3 - m\right) g}{\pi r^2 \rho}}$$

Substitute numerical values and evaluate v:

$$v_t = \sqrt{\frac{2\left[\tfrac{4}{3}\pi\left(1.29\,\text{kg/m}^3\right)\left(2.5\,\text{m}\right)^3 - 15\,\text{kg}\right]\left(9.81\,\text{m/s}^2\right)}{\pi\left(2.5\,\text{m}\right)^2\left(1.29\,\text{kg/m}^3\right)}} = 7.33\,\text{m/s} = \boxed{7.3\,\text{m/s}}$$

53 ••• [SSM] A ship sails from seawater (specific gravity 1.025) into freshwater, and therefore sinks slightly. When its 600,000-kg load is removed, it returns to its original level. Assuming that the sides of the ship are vertical at the water line, find the mass of the ship before it was unloaded.

Picture the Problem Let V = displacement of ship in the two cases, m be the mass of ship without load, and Δm be the load. The ship is in equilibrium under the influence of the buoyant force exerted by the water and its weight. We'll apply the condition for floating in the two cases and solve the equations simultaneously to determine the loaded mass of the ship.

Apply $\sum F_y = 0$ to the ship in fresh water:

$$\rho_{\text{w}} Vg - mg = 0 \quad (1)$$

Apply $\sum F_y = 0$ to the ship in salt water:

$$\rho_{\text{sw}} Vg - (m + \Delta m)g = 0 \quad (2)$$

Solve equation (1) for Vg:

$$Vg = \frac{mg}{\rho_{\text{w}}}$$

Substitute in equation (2) to obtain:

$$\rho_{\text{sw}} \frac{mg}{\rho_{\text{w}}} - (m + \Delta m)g = 0$$

Solving for m yields:

$$m = \frac{\rho_{\text{w}} \Delta m}{\rho_{\text{sw}} - \rho_{\text{w}}}$$

Add Δm to both sides of the equation and simplify to obtain:

$$\begin{aligned} m + \Delta m &= \frac{\rho_{\text{w}} \Delta m}{\rho_{\text{sw}} - \rho_{\text{w}}} + \Delta m \\ &= \Delta m \left(\frac{\rho_{\text{w}}}{\rho_{\text{sw}} - \rho_{\text{w}}} + 1 \right) \\ &= \frac{\Delta m \rho_{\text{sw}}}{\rho_{\text{sw}} - \rho_{\text{w}}} \end{aligned}$$

Substitute numerical values and evaluate $m + \Delta m$:

$$\begin{aligned} m + \Delta m &= \frac{(6.00 \times 10^5\ \text{kg})(1.025\rho_{\text{w}})}{1.025\rho_{\text{w}} - \rho_{\text{w}}} \\ &= \frac{(6.00 \times 10^5\ \text{kg})(1.025)}{1.025 - 1} \\ &= \boxed{2.5 \times 10^7\ \text{kg}} \end{aligned}$$

Continuity and Bernoulli's Equation

54 • Water flows at 0.65 m/s through a 3.0-cm-diameter hose that terminates in a 0.30-cm-diameter nozzle. Assume laminar nonviscous steady-state flow. (*a*) At what speed does the water pass through the nozzle? (*b*) If the pump at one end of the hose and the nozzle at the other end are at the same height, and if the pressure at the nozzle is 1.0 atm, what is the pressure at the pump outlet?

Picture the Problem Let A_1 represent the cross-sectional area of the hose, A_2 the cross-sectional area of the nozzle, v_1 the speed of the water in the hose, and v_2 the speed of the water as it passes through the nozzle. We can use the continuity

equation to find v_2 and Bernoulli's equation for constant elevation to find the pressure at the pump outlet.

(*a*) Using the continuity equation, relate the speeds of the water to the diameter of the hose and the diameter of the nozzle:

$$A_1v_1 = A_2v_2$$

or

$$\frac{\pi d_1^2}{4}v_1 = \frac{\pi d_2^2}{4}v_2 \Rightarrow v_2 = \frac{d_1^2}{d_2^2}v_1$$

Substitute numerical values and evaluate v_2:

$$v_2 = \left(\frac{3.0\,\text{cm}}{0.30\,\text{cm}}\right)^2(0.65\,\text{m/s}) = 65.0\,\text{m/s}$$

$$= \boxed{65\,\text{m/s}}$$

(*b*) Using Bernoulli's equation for constant elevation, relate the pressure at the pump P_P to the atmospheric pressure and the velocities of the water in the hose and the nozzle:

$$P_P + \tfrac{1}{2}\rho v_1^2 = P_{at} + \tfrac{1}{2}\rho v_2^2$$

Solve for the pressure at the pump:

$$P_P = P_{at} + \tfrac{1}{2}\rho\left(v_2^2 - v_1^2\right)$$

Substitute numerical values and evaluate P_P:

$$P_P = 101.325\,\text{kPa} + \tfrac{1}{2}\left(1.00\times10^3\,\text{kg/m}^3\right)\left[(65.0\,\text{m/s})^2 - (0.65\,\text{m/s})^2\right]$$

$$= 2.21\times10^6\,\text{Pa}\times\frac{1\,\text{atm}}{101.325\,\text{kPa}} = \boxed{22\,\text{atm}}$$

55 • [SSM] Water is flowing at 3.00 m/s in a horizontal pipe under a pressure of 200 kPa. The pipe narrows to half its original diameter. (*a*) What is the speed of flow in the narrow section? (*b*) What is the pressure in the narrow section? (*c*) How do the volume flow rates in the two sections compare?

Picture the Problem Let A_1 represent the cross-sectional area of the larger-diameter pipe, A_2 the cross-sectional area of the smaller-diameter pipe, v_1 the speed of the water in the larger-diameter pipe, and v_2 the velocity of the water in the smaller-diameter pipe. We can use the continuity equation to find v_2 and Bernoulli's equation for constant elevation to find the pressure in the smaller-diameter pipe.

(*a*) Using the continuity equation, relate the velocities of the water to the diameters of the pipe:

$$A_1v_1 = A_2v_2$$

or

$$\frac{\pi d_1^2}{4}v_1 = \frac{\pi d_2^2}{4}v_2 \Rightarrow v_2 = \frac{d_1^2}{d_2^2}v_1$$

Substitute numerical values and evaluate v_2:

$$v_2 = \left(\frac{d_1}{\frac{1}{2}d_1}\right)^2(3.00\,\text{m/s}) = \boxed{12.0\,\text{m/s}}$$

(*b*) Using Bernoulli's equation for constant elevation, relate the pressures in the two segments of the pipe to the velocities of the water in these segments:

$$P_1 + \tfrac{1}{2}\rho_\text{w}v_1^2 = P_2 + \tfrac{1}{2}\rho_\text{w}v_2^2$$

Solving for P_2 yields:

$$\begin{aligned} P_2 &= P_1 + \tfrac{1}{2}\rho_\text{w}v_1^2 - \tfrac{1}{2}\rho_\text{w}v_2^2 \\ &= P_1 + \tfrac{1}{2}\rho_\text{w}\left(v_1^2 - v_2^2\right) \end{aligned}$$

Substitute numerical values and evaluate P_2:

$$P_2 = 200\,\text{kPa} + \tfrac{1}{2}\left(1.00\times10^3\ \text{kg/m}^3\right)\left[(3.00\,\text{m/s})^2 - (12.0\,\text{m/s})^2\right] = \boxed{133\,\text{kPa}}$$

(*c*) From the continuity equation; $\boxed{I_{\text{V}1} = I_{\text{V}2}}$.

56 •• The pressure in a section of horizontal pipe with a diameter of 2.00 cm is 142 kPa. Water flows through the pipe at 2.80 L/s. If the pressure at a certain point is to be reduced to 101 kPa by constricting a section of the pipe, what should the diameter of the constricted section be?

Picture the Problem Let A_1 represent the cross-sectional area of the 2.00-cm diameter pipe, A_2 the cross-sectional area of the constricted pipe, v_1 the speed of the water in the 2.00-cm diameter pipe, and v_2 the speed of the water in the constricted pipe. We can use the continuity equation to express d_2 in terms of d_1 and to find v_1 and Bernoulli's equation for constant elevation to find the speed of the water in the constricted pipe.

Using the continuity equation, relate the volume flow rate in the 2.00-cm diameter pipe to the volume flow rate in the constricted pipe:

$$A_1v_1 = A_2v_2$$

or

$$\frac{\pi d_1^2}{4}v_1 = \frac{\pi d_2^2}{4}v_2 \Rightarrow d_2 = d_1\sqrt{\frac{v_1}{v_2}} \quad (1)$$

Using the continuity equation, relate v_1 to the volume flow rate I_V:

$$v_1 = \frac{I_V}{A_1} = \frac{I_V}{\frac{1}{4}\pi d_1^2} = \frac{4I_V}{\pi d_1^2}$$

Using Bernoulli's equation for constant elevation, relate the pressures in the two segments of the pipe to the velocities of the water in these segments:

$$P_1 + \tfrac{1}{2}\rho_w v_1^2 = P_2 + \tfrac{1}{2}\rho_w v_2^2$$

Solve for v_2 to obtain:

$$v_2 = \sqrt{\frac{2(P_1 - P)}{\rho_w} + v_1^2}$$

Substituting for v_2 in equation (1) and simplifying yields:

$$d_2 = d_1\sqrt{\frac{v_1}{\sqrt{\frac{2(P_1-P)}{\rho_w} + v_1^2}}} = d_1\sqrt{\frac{1}{\sqrt{\frac{2(P_1-P)}{v_1^2\rho_w} + 1}}} = \frac{d_1}{\sqrt[4]{\frac{2(P_1-P)}{v_1^2\rho_w} + 1}}$$

Substitute for v_1 and simplify to obtain:

$$d_2 = \frac{d_1}{\sqrt[4]{\frac{2(P_1-P)}{\left(\frac{4I_V}{\pi d_1^2}\right)^2\rho_w} + 1}} = \frac{d_1}{\sqrt[4]{\frac{\pi^2 d_1^4(P_1-P)}{8I_V^2\rho_w} + 1}}$$

Substitute numerical values and evaluate d_2:

$$d_2 = \frac{2.00\,\text{cm}}{\sqrt[4]{\frac{\pi^2(0.0200\,\text{m})^4(142\,\text{kPa} - 101.325\,\text{kPa})}{8(2.80\,\text{L/s})^2(1.00\times10^3\,\text{kg/m}^3)} + 1}} = \boxed{1.68\,\text{cm}}$$

57 •• [SSM] Blood flows at at 30 cm/s in an aorta of radius 9.0 mm. (*a*) Calculate the volume flow rate in liters per minute. (*b*) Although the cross-sectional area of a capillary is much smaller than that of the aorta, there are many capillaries, so their total cross-sectional area is much larger. If all the blood from the aorta flows into the capillaries and the speed of flow through the capillaries is 1.0 mm/s, calculate the total cross-sectional area of the capillaries. Assume laminar nonviscous, steady-state flow.

Picture the Problem We can use the definition of the volume flow rate to find the volume flow rate of blood in an aorta and to find the total cross-sectional area of the capillaries.

(*a*) Use the definition of the volume flow rate to find the volume flow rate through an aorta:

$$I_V = Av$$

Substitute numerical values and evaluate I_V:

$$I_V = \pi\left(9.0\times10^{-3}\ \text{m}\right)^2 (0.30\ \text{m/s})$$
$$= 7.634\times10^{-5}\ \frac{\text{m}^3}{\text{s}}\times\frac{60\ \text{s}}{\text{min}}\times\frac{1\ \text{L}}{10^{-3}\ \text{m}^3}$$
$$= 4.58\ \text{L/min} = \boxed{4.6\ \text{L/min}}$$

(*b*) Use the definition of the volume flow rate to express the volume flow rate through the capillaries:

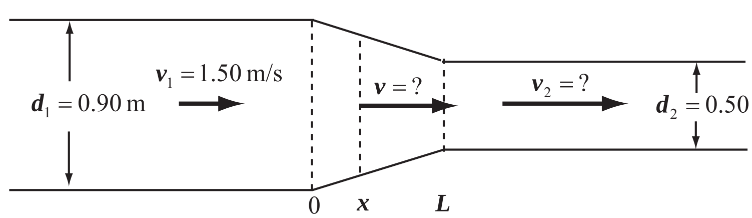
$$I_V = A_{\text{cap}}v_{\text{cap}} \Rightarrow A_{\text{cap}} = \frac{I_V}{v_{\text{cap}}}$$

Substitute numerical values and evaluate A_{cap}:

$$A_{\text{cap}} = \frac{7.63\times10^{-5}\ \text{m}^3/\text{s}}{0.0010\ \text{m/s}} = \boxed{7.6\times10^{-2}\ \text{m}^2}$$

58 •• Water flows through a 1.0 m-long conical section of pipe that joins a cylindrical pipe of radius 0.45 m, on the left, to a cylindrical pipe of radius 0.25 m, on the right. If the water is flowing into the 0.45 m pipe with a speed of 1.50 m/s, and if we assume laminar nonviscous steady-state flow, (*a*) what is the speed of flow in the 0.25 m pipe? (*b*) What is the speed of flow at a position *x* in the conical section, if *x* is the distance measured from the left-hand end of the conical section of pipe?

Picture the Problem The pictorial representation summarizes what we know about the two pipes and the connecting conical section. We can apply the continuity equation to find v_2. We can also use the continuity equation in (*b*) provided we first express the cross-sectional area of the transitional conical section as a function of *x*.



(*a*) Apply the continuity equation to the flow in the two sections of cylindrical pipes:

$$v_1A_1 = v_2A_2$$

Solving for v_2, expressing the cross-sectional areas in terms of their diameters, and simplifying yields:

$$v_2 = v_1 \frac{A_1}{A_2} = v_1 \frac{\frac{1}{4}\pi d_1^2}{\frac{1}{4}\pi d_2^2} = v_1 \left(\frac{d_1}{d_2}\right)^2$$

Substitute numerical values and evaluate v_2:

$$v_2 = (1.50\text{ m/s})\left(\frac{0.90\text{ m}}{0.50\text{ m}}\right)^2 = \boxed{4.9\text{ m/s}}$$

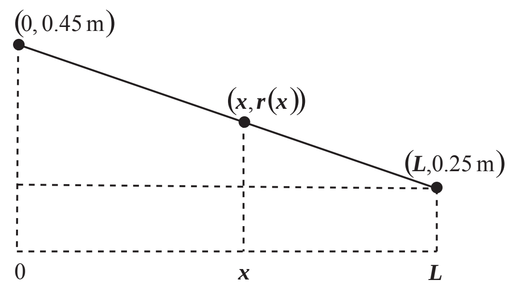
(*b*) Continuity of flow requires that:

$$v(0)A(0) = v(x)A(x)$$

Solve for $v(x)$ to obtain:

$$v(x) = v(0)\frac{A(0)}{A(x)} \qquad (1)$$

The diagram to the right is an enlargement of the upper half of the transitional conical section. Use the coordinates shown on the line to establish the following proportion:



$$\frac{r(x) - 0.45\text{ m}}{x - 0} = \frac{0.25\text{ m} - 0.45\text{ m}}{L - 0}$$

Solving the proportion for $r(x)$ yields:

$$r(x) = 0.45\text{ m} - (0.20\text{ m})\frac{x}{L}$$

where L is the length of the conical section.

The cross-sectional area of the conical section varies with x according to:

$$A(x) = \pi (r(x))^2 = \pi\left(0.45\text{ m} - (0.20\text{ m})\frac{x}{L}\right)^2$$

Substituting for $A(x)$ in equation (1) and simplifying yields:

$$v(x) = v(0)\frac{\pi r_1^2}{\pi\left(0.45\text{ m} - (0.20\text{ m})\frac{x}{L}\right)^2} = \frac{v(0) r_1^2}{\left(0.45\text{ m} - (0.20\text{ m})\frac{x}{L}\right)^2}$$

Substitute numerical values and simplify further to obtain:

$$v(x)=\frac{(1.50\ \text{m/s})(0.45\ \text{m})^2}{\left(0.45\ \text{m}-(0.20\ \text{m})\dfrac{x}{1.0\ \text{m}}\right)^2}=\boxed{\frac{0.304\ \text{m}^3/\text{s}}{(0.45\ \text{m}-0.20x)^2}}$$

To confirm the correctness of this equation, evaluate $v(0)$ and $v(1.0\ \text{m})$:

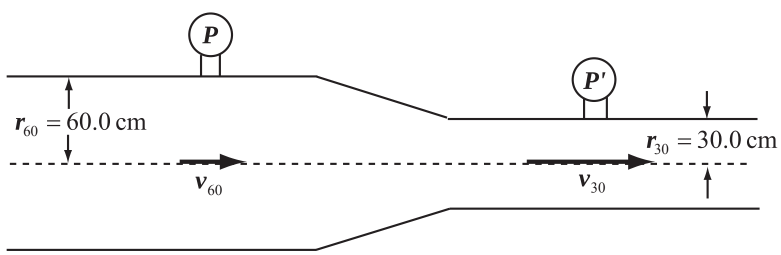
$$v(0)=\frac{0.304\ \text{m}^3/\text{s}}{(0.45\ \text{m})^2}=1.5\ \text{m/s}$$

and

$$v(1.0\ \text{m})=\frac{0.304\ \text{m}^3/\text{s}}{(0.45\ \text{m}-0.20(1.0\ \text{m}))^2}=4.9\ \text{m/s}$$

59 •• The \$8-billion, 800-mile-long Alaskan Pipeline has a maximum volume flow rate of 240,000 m^3 of oil per day. Most of the pipeline has a radius of60.0 cm. Find the pressure P' at a point where the pipe has a 30.0-cm radius. Take the pressure in the 60.0-cm-radius sections to be P = 180 kPa and the density of oil to be 800 kg/m^3. Assume laminar nonviscous steady-state flow.

Picture the Problem Let the subscript 60 denote the 60.0-cm-radius pipe and the subscript 30 denote the 30.0-cm-radius pipe. We can use Bernoulli's equation for constant elevation to express P' in terms of v_{60} and v_{30}, the definition of volume flow rate to find v_{60}, and the continuity equation to find v_{30}.



Using Bernoulli's equation for constant elevation, relate the pressures in the two pipes to the velocities of the oil:

$$P+\tfrac{1}{2}\rho v_{60}^2=P'+\tfrac{1}{2}\rho v_{30}^2$$

Solving for P' yields:

$$P'=P+\tfrac{1}{2}\rho\left(v_{60}^2-v_{30}^2\right) \qquad (1)$$

Use the definition of volume flow rate to express v_{60}:

$$v_{60}=\frac{I_V}{A_{60}}=\frac{I_V}{\pi r_{60}^2}$$

Using the continuity equation, relate the speed of the oil in the half-standard pipe to its speed in the standard pipe:

$$A_{60}v_{60} = A_{30}v_{30} \Rightarrow v_{30} = \frac{A_{60}}{A_{30}}v_{60}$$

Substituting for v_{60} and A_{30} yields:

$$v_{30} = \frac{A_{60}}{A_{30}}\frac{I_V}{A_{60}} = \frac{I_V}{A_{30}} = \frac{I_V}{\pi r_{30}^2}$$

Substitute for v_{60} and v_{30} and simplify to obtain:

$$P' = P + \tfrac{1}{2}\rho\left(\left(\frac{I_V}{\pi r_{60}^2}\right)^2 - \left(\frac{I_V}{\pi r_{30}^2}\right)^2\right) = P + \frac{\rho I_V^2}{2\pi^2}\left(\frac{1}{r_{60}^4} - \frac{1}{r_{30}^4}\right)$$

Substitute numerical values in equation (1) and evaluate P':

$$P' = 180\,\text{kPa} + \frac{\left(800\,\text{kg/m}^3\right)\left(2.40\times10^5\,\frac{\text{m}^3}{\text{d}}\times\frac{1\,\text{d}}{24\,\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{2\pi^2}$$
$$\times\left(\frac{1}{(0.600\,\text{m})^4} - \frac{1}{(0.300\,\text{m})^4}\right)$$
$$= \boxed{144\,\text{kPa}}$$

60 •• Water flows through a Venturi meter like that in Example 13-11 with a pipe diameter of 9.50 cm and a constriction diameter of 5.60 cm. The U-tube manometer is partially filled with mercury. Find the volume flow rate of the water if the difference in the mercury level in the U-tube is 2.40 cm.

Picture the Problem We'll use its definition to relate the volume flow rate in the pipe to the speed of the water and the result of Example 13-11 to find the speed of the water.

Using its definition, express the volume flow rate:

$$I_V = A_1 v_1 = \pi r^2 v_1$$

Using the result of Example 13-11, find the speed of the water upstream from the Venturi meter:

$$v_1 = \sqrt{\frac{2\rho_{Hg}gh}{\rho_w\left(\frac{R_1^2}{R_2^2} - 1\right)}}$$

Substituting for v_1 yields:

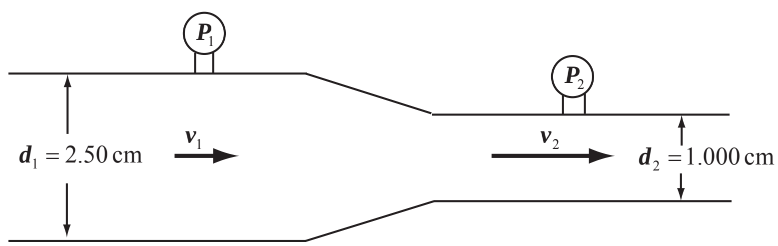
$$I_V = \pi r^2 \sqrt{\frac{2\rho_{Hg} g h}{\rho_w \left(\frac{R_1^2}{R_2^2} - 1\right)}}$$

Substitute numerical values and evaluate I_V:

$$I_V = \frac{\pi}{4}(0.0950\,\text{m})^2 \sqrt{\frac{2(13.6\times10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)(0.0240\,\text{m})}{(1.00\times10^3\ \text{kg/m}^3)\left[\left(\frac{0.0950\,\text{m}}{0.0560\,\text{m}}\right)^2 - 1\right]}} = \boxed{13.1\,\text{L/s}}$$

61 •• [SSM] Horizontal flexible tubing for carrying cooling water extends through a large electromagnet used in your physics experiment at Fermi National Accelerator Laboratory. A minimum volume flow rate of 0.050 L/s through the tubing is necessary in order to keep your magnet cool. Within the magnet volume, the tubing has a circular cross section of radius 0.500 cm. In regions outside the magnet, the tubing widens to a radius of 1.25 cm. You have attached pressure sensors to measure differences in pressure between the 0.500 cm and 1.25 cm sections. The lab technicians tell you that if the flow rate in the system drops below 0.050 L/s, the magnet is in danger of overheating and that you should install an alarm to sound a warning when the flow rate drops below that level. What is the critical pressure difference at which you should program the sensors to send the alarm signal (and is this a minimum, or maximum, pressure difference)? Assume laminar nonviscous steady-state flow.

Picture the Problem The pictorial representation shows the narrowing of the cold-water supply tubes as they enter the magnet. We can apply Bernoulli's equation and the continuity equation to derive an expression for the pressure difference $P_1 - P_2$.



Apply Bernoulli's equation to the two sections of tubing to obtain:

$$P_1 + \tfrac{1}{2}\rho v_1^2 = P_2 + \tfrac{1}{2}\rho v_2^2$$

Solving for the pressure difference $P_1 - P_2$ yields:

$$\Delta P = P_1 - P_2 = \tfrac{1}{2}\rho v_2^2 - \tfrac{1}{2}\rho v_1^2 = \tfrac{1}{2}\rho\left(v_2^2 - v_1^2\right)$$

Factor v_1^2 from the parentheses to obtain:

$$\Delta P = \tfrac{1}{2}\rho v_1^2\left(\frac{v_2^2}{v_1^2}-1\right) = \tfrac{1}{2}\rho v_1^2\left(\left(\frac{v_2}{v_1}\right)^2-1\right)$$

From the continuity equation we have:

$$A_1 v_1 = A_2 v_2$$

Solving for the ratio of v_2 to v_1, expressing the areas in terms of the diameters, and simplifying yields:

$$\frac{v_2}{v_1} = \frac{A_1}{A_2} = \frac{\frac{1}{4}\pi d_1^2}{\frac{1}{4}\pi d_2^2} = \left(\frac{d_1}{d_2}\right)^2$$

Use the expression for the volume flow rate to express v_1:

$$v_1 = \frac{I_V}{A_1} = \frac{I_V}{\frac{1}{4}\pi d_1^2} = \frac{4I_V}{\pi d_1^2}$$

Substituting for v_1 and v_2/v_1 in the expression for ΔP yields:

$$\Delta P = \tfrac{1}{2}\rho\left(\frac{4I_V}{\pi d_1^2}\right)^2\left(\left(\frac{d_1}{d_2}\right)^4-1\right)$$

Substitute numerical values and evaluate ΔP:

$$\Delta P = \tfrac{1}{2}\left(1.00\times10^3\ \text{kg/m}^3\right)\left(\frac{4\left(0.050\ \frac{\text{L}}{\text{s}}\times\frac{10^{-3}\ \text{m}^3}{\text{L}}\right)}{\pi(0.0250\ \text{m})^2}\right)^2\left(\left(\frac{2.50\ \text{cm}}{1.000\ \text{cm}}\right)^4-1\right) = \boxed{0.20\ \text{kPa}}$$

Because $\Delta P \propto I_V^2$ (ΔP as a function of I_V is a parabola that opens upward), this pressure difference is the minimum pressure difference.

62 •• Figure 13-37 shows a Pitot-static tube, a device used for measuring the speed of a gas. The inner pipe faces the incoming fluid, while the ring of holes in the outer tube is parallel to the gas flow. Show that the speed of the gas is given by $v = \sqrt{\frac{2gh(\rho_L - \rho_g)}{\rho_g}}$, where ρ_L is the density of the liquid used in the manometer and ρ_g is the density of the gas.

Picture the Problem Let the numeral 1 denote the opening in the end of the inner pipe and the numeral 2 to one of the holes in the outer tube. We can apply Bernoulli's principle at these locations and solve for the pressure difference between them. By equating this pressure difference to the pressure difference due to the height h of the liquid column we can express the speed of the gas as a function of ρ_L, ρ_g, g, and h.

Apply Bernoulli's principle at locations 1 and 2 to obtain:

$P_1 + \frac{1}{2}\rho_g v_1^2 = P_2 + \frac{1}{2}\rho_g v_2^2$
where we've ignored the difference in elevation between the two openings.

Solve for the pressure difference $\Delta P = P_1 - P_2$:

$\Delta P = P_1 - P_2 = \frac{1}{2}\rho_g v_2^2 - \frac{1}{2}\rho_g v_1^2$

Express the speed of the gas at 1:

Because the gas is brought to a halt (that is, is stagnant) at the opening to the inner pipe, $v_1 = 0$.

Express the speed of the gas at 2:

Because the gas flows freely past the holes in the outer ring, $v_2 = v$.

Substitute to obtain:

$\Delta P = \frac{1}{2}\rho_g v^2$

Letting A be the cross-sectional area of the tube, express the pressure at a depth h in the column of liquid whose density is ρ_l:

$$P_1 = P_2 + \frac{w_{\text{displaced liquid}}}{A} - \frac{B}{A}$$
where $B = \rho_g Ahg$ is the buoyant force acting on the column of liquid of height h.

Substitute to obtain:

$$P_1 = P_2 + \frac{\rho_L ghA}{A} - \frac{\rho_g ghA}{A}$$
$$= P_2 + (\rho_L - \rho_g)gh$$
or
$$\Delta P = P_1 - P_2 = (\rho_L - \rho_g)gh$$

Equate these two expressions for ΔP:

$\frac{1}{2}\rho_g v^2 = (\rho_L - \rho_g)gh$

Solving for v yields:

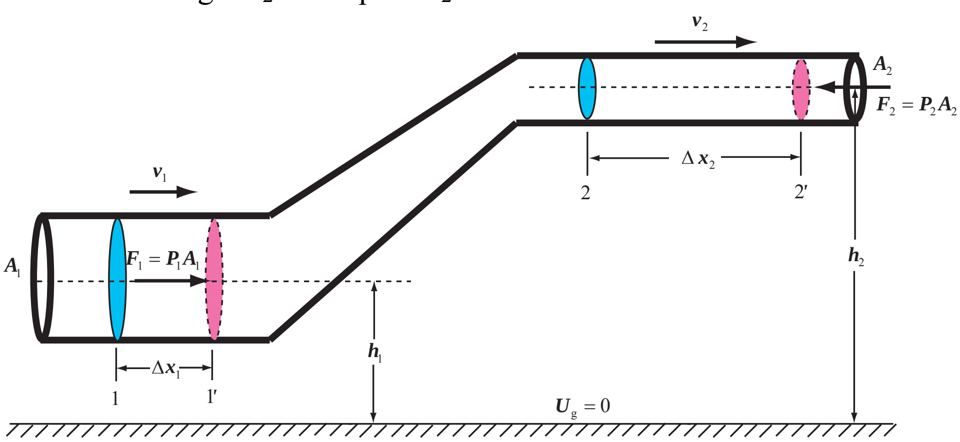
$$v = \boxed{\sqrt{\frac{2gh(\rho_L - \rho_g)}{\rho_g}}}$$

Note that the correction for buoyant force due to the displaced gas is very small and that, to a good approximation, $v = \sqrt{\frac{2gh\rho_L}{\rho_g}}$.

Remarks: Pitot tubes are used to measure the airspeed of airplanes.

63 ••• **[SSM]** Derive the Bernoulli Equation in more generality than done in the text, that is, allow for the fluid to change elevation during its movement. Using the work-energy theorem, show that when changes in elevation are allowed, Equation 13-16 becomes $P_1 + \rho g h_1 + \frac{1}{2}\rho v_1^2 = P_2 + \rho g h_2 + \frac{1}{2}\rho v_2^2$ (Equation 13-17).

Picture the Problem Consider a fluid flowing in a tube that varies in elevation as well as in cross-sectional area, as shown in the pictorial representation below. We can apply the work-energy theorem to a parcel of fluid that initially is contained between points 1 and 2. During time Δt this parcel moves along the tube to the region between point 1′ and 2′. Let ΔV be the volume of fluid passing point 1′ during time Δt. The same volume passes point 2 during the same time. Also, let $\Delta m = \rho\Delta V$ be the mass of the fluid with volume ΔV. The net effect on the parcel during time Δt is that mass Δm initially at height h_1 moving with speed v_1 is "transferred" to height h_2 with speed v_2.



Express the work-energy theorem:

$$W_{\text{total}} = \Delta U + \Delta K \qquad (1)$$

The change in the potential energy of the parcel is given by:

$$\begin{aligned}\Delta U &= (\Delta m)gh_2 - (\Delta m)gh_1 \\ &= (\Delta m)g(h_2 - h) \\ &= \rho\Delta V g(h_2 - h_1)\end{aligned}$$

The change in the kinetic energy of the parcel is given by:

$$\begin{aligned}\Delta K &= \tfrac{1}{2}(\Delta m)v_2^2 - \tfrac{1}{2}(\Delta m)v_1^2 \\ &= \tfrac{1}{2}(\Delta m)(v_2^2 - v_1^2) \\ &= \tfrac{1}{2}\rho\Delta V(v_2^2 - v_1^2)\end{aligned}$$

Express the work done by the fluid behind the parcel (to the parcel's left in the diagram) as it pushes on the parcel with a force of magnitude $F_1 = P_1A_1$, where P_1 is the pressure at point 1:

$$W_1 = F_1\Delta x_1 = P_1A_1\Delta x_1 = P_1\Delta V$$

Express the work done by the fluid in front of the parcel (to the parcel's right in the diagram) as it pushes on the parcel with a force of magnitude $F_2 = P_2 A_2$, where P_2 is the pressure at point 2:

$$W_2 = -F_2\Delta x_2 = -P_2 A_2 \Delta x_2 = -P_2 \Delta V$$

where the work is negative because the applied force and the displacement are in opposite directions.

The total work done on the parcel is:

$$W_{\text{total}} = P_1\Delta V - P_2 \Delta V = (P_1 - P_2)\Delta V$$

Substitute for ΔU, ΔK, and W_{total} in equation (1) to obtain:

$$(P_1 - P_2)\Delta V = \rho \Delta V g(h_2 - h_1) + \tfrac{1}{2}\rho \Delta V\left(v_2^2 - v_1^2\right)$$

Simplifying this expression by dividing out ΔV yields:

$$P_1 - P_2 = \rho g(h_2 - h_1) + \tfrac{1}{2}\rho\left(v_2^2 - v_1^2\right)$$

Collect all the quantities having a subscript 1 on one side and those having a subscript 2 on the other to obtain:

$$\boxed{P_1 + \rho g h_1 + \tfrac{1}{2}\rho v_1^2 = P_2 + \rho g h_2 + \tfrac{1}{2}\rho v_2^2}$$

Remarks: This equation is known as Bernoulli's equation for the steady, nonviscous flow of an incompressible fluid.

64 ••• A large keg of height H and cross-sectional area A_1 is filled with root beer. The top is open to the atmosphere. There is a spigot opening of area A_2, which is much smaller than A_1, at the bottom of the keg. (*a*) Show that when the height of the root beer is h, the speed of the root beer leaving the spigot is approximately $\sqrt{2gh}$. (*b*) Show that if $A_2 << A_1$, the rate of change of the height h of the root beer is given by $dh/dt = -(A_2/A_1)(2gh)^{1/2}$. (*c*) Find h as a function of time if $h = H$ at $t = 0$. (*d*) Find the total time needed to drain the keg if $H = 2.00$ m, $A_1 = 0.800$ m^2, and $A_2 = 1.00 \times 10^{-4}\,A_1$. Assume laminar nonviscous flow.

Picture the Problem We can apply Bernoulli's equation to the top of the keg and to the spigot opening to determine the rate at which the root beer exits the tank. Because the area of the spigot is much smaller than that of the keg, we can neglect the speed of the root beer at the top of the keg. We'll use the continuity equation to obtain an expression for the rate of change of the height of the root beer in the keg as a function of the height and integrate this function to find h as a function of time.

(a) Apply Bernoulli's equation to the beer at the top of the keg and at the spigot:

$$P_1+\rho_{\text{beer}}gh_1+\tfrac{1}{2}\rho_{\text{beer}}v_1^2=P_2+\rho_{\text{beer}}gh_2+\tfrac{1}{2}\rho_{\text{beer}}v_2^2$$

or, because $v_1 \approx 0$, $h_2 = 0$, $P_1 = P_2 = P_{\text{at}}$, and $h_1 = h$,

$$gh=\tfrac{1}{2}v_2^2 \Rightarrow v_2=\boxed{\sqrt{2gh}}$$

(b) Use the continuity equation to relate v_1 and v_2:

$$A_1v_1=A_2v_2$$

Substitute $-dh/dt$ for v_1 and $\sqrt{2gh}$ for v_2 to obtain:

$$-A_1\frac{dh}{dt}=A_2\sqrt{2gh}$$

Solving for dh/dt yields:

$$\frac{dh}{dt}=\boxed{-\frac{A_2}{A_1}\sqrt{2gh}}$$

(c) Separate the variables in the differential equation to obtain:

$$-\frac{A_1/A_2}{\sqrt{2g}}\frac{dh}{\sqrt{h}}=dt$$

Express the integral from H to h and 0 to t:

$$-\frac{A_1/A_2}{\sqrt{2g}}\int_H^h\frac{dh}{\sqrt{h}}=\int_0^t dt$$

Evaluate the integral to obtain:

$$-\frac{2A_1/A_2}{\sqrt{2g}}\left(\sqrt{H}-\sqrt{h}\right)=t$$

Solving for h gives:

$$h=\boxed{\left(\sqrt{H}-\frac{A_2}{2A_1}\sqrt{2g}\,t\right)^2}$$

(d) Solve $h(t)$ for the time-to-drain t':

$$t'=\frac{A_1}{A_2}\sqrt{\frac{2H}{g}}$$

Substitute numerical values and evaluate t'

$$t'=\frac{A_1}{1.00\times10^{-4}A_1}\sqrt{\frac{2(2.00\,\text{m})}{9.81\,\text{m/s}^2}}=6.39\times10^3\,\text{s}=\boxed{1\,\text{h}\ 46\,\text{min}}$$

65 •• A siphon is a device for transferring a liquid from container to container. The tube shown in Figure 13-38 must be filled to start the siphon, but once this has been done, fluid will flow through the tube until the liquid surfaces in the containers are at the same level. (a) Using Bernoulli's equation, show that

the speed of water in the tube is $v = \sqrt{2gd}$. (*b*) What is the pressure at the highest part of the tube?

Picture the Problem Let the letter ″a″ denote the entrance to the siphon tube and the letter ″b″ denote its exit and assume that ″b″ in at the surface of the liquid in the container to the right. Assuming streamline flow between these points, we can apply Bernoulli's equation to relate the entrance and exit speeds of the water flowing in the siphon to the pressures at either end, the density of the water, and the difference in elevation between the entrance and exit points. We'll also use the equation of continuity to argue that, provided the surface area of the beaker is large compared to the area of the opening of the tube, the entrance speed of the water is approximately zero.

(*a*) Assuming that the height of the containers is *H,* apply Bernoulli's equation at the surface of the left container and at point b:

$$P_{\text{at}} + \tfrac{1}{2}\rho v_{\text{surface}}^2 + \rho g(H-h) = P_{\text{at}} + \tfrac{1}{2}\rho v_{\text{b}}^2 + \rho g(H-h-d) \qquad (1)$$

Apply the continuity equation to a point at the surface of the liquid in the container to the left and to point b:

$$v_{\text{b}}A_{\text{b}} = v_{\text{surface}}A_{\text{surface}} \Rightarrow v_{\text{surface}} = v_{\text{b}}\frac{A_{\text{b}}}{A_{\text{surface}}}$$

or, because $A_{\text{surface}} >> A_{\text{b}}$,

$v_{\text{surface}} = 0$

With $v_{\text{a}} = 0$, equation (1) becomes:

$$\rho g(H-h) = \tfrac{1}{2}\rho v_{\text{b}}^2 + \rho g(H-h-d)$$

Solving for v_{b} gives:

$$v_{\text{b}} = \boxed{\sqrt{2gd}}$$

(*b*) Relate the pressure at the highest part of the tube P_{top} to the pressure at point b:

$$P_{\text{top}} + \rho g(H-h) + \tfrac{1}{2}\rho v_{\text{top}}^2 = P_{\text{at}} + \rho g(H-h-d) + \tfrac{1}{2}\rho v_{\text{b}}^2$$

The equation of continuity requires that $v_{\text{top}} = v_{\text{b}} = v_{\text{a}}$:

$$P_{\text{top}} + \rho g(H-h) + \tfrac{1}{2}\rho v_{\text{top}}^2 = P_{\text{at}} + \rho g(H-h-d) + \tfrac{1}{2}\rho v_{\text{top}}^2$$

or, simplifying,

$$P_{\text{top}} + \rho g(H-h) = P_{\text{at}} + \rho g(H-h-d)$$

Solve for P_{top} to obtain:

$$P_{\text{top}} = \boxed{P_{\text{at}} - \rho g d}$$

Remarks: If we let P_{top} = 0, we can use this result to find the maximum theoretical height a siphon can lift water.

66 •• A fountain designed to spray a column of water 12 m into the air has a 1.0-cm-diameter nozzle at ground level. The water pump is 3.0 m below the ground. The pipe to the nozzle has a diameter of 2.0 cm. Find pump pressure necessary if the fountain is to operate as designed. (Assume laminar nonviscous steady-state flow.)

Picture the Problem Let the letter P denote the pump and the 2.0-cm diameter pipe and the letter N the 1-cm diameter nozzle. We'll use Bernoulli's equation to express the necessary pump pressure, the continuity equation to relate the speed of the water coming out of the pump to its speed at the nozzle, and a constant-acceleration equation to relate its speed at the nozzle to the height to which the water rises.

Using Bernoulli's equation, relate the pressures, areas, and velocities in the pipe and nozzle:

$$P_P + \rho_w g h_P + \tfrac{1}{2}\rho_w v_P^2 = P_N + \rho_w g h_N + \tfrac{1}{2}\rho_w v_N^2$$

or, because $P_N = P_{at}$ and $h_P = 0$,

$$P_P + \tfrac{1}{2}\rho_w v_P^2 = P_N + \rho_w g h_N + \tfrac{1}{2}\rho_w v_N^2$$

Solve for the pump pressure:

$$P_P = P_{at} + \rho_w g h_N + \tfrac{1}{2}\rho_w\left(v_N^2 - v_P^2\right) \quad (1)$$

Use the continuity equation to relate v_P and v_N to the cross-sectional areas of the pipe from the pump and the nozzle:

$$A_P v_P = A_N v_N$$

and

$$v_P = \frac{A_N}{A_P} v_N = \frac{\frac{1}{4}\pi d_N^2}{\frac{1}{4}\pi d_P^2} v_N = \left(\frac{1.0\,\text{cm}}{2.0\,\text{cm}}\right)^2 v_N = \tfrac{1}{4} v_N$$

Use a constant-acceleration equation to express the speed of the water at the nozzle in terms of the desired height Δh:

$$v^2 = v_N^2 - 2g\Delta h$$

or, because $v = 0$,

$$v_N^2 = 2g\Delta h$$

Substitute for v_N and v_P in equation (1) and simplify to obtain:

$$P_P = P_{at} + \rho_w g h_N + \tfrac{1}{2}\rho_w\left[2g\Delta h - \tfrac{1}{16}(2g\Delta h)\right] = P_{at} + \rho_w g h_N + \tfrac{1}{2}\rho_w\left(\tfrac{15}{8} g\Delta h\right)$$
$$= P_{at} + \rho_w g\left(h_N + \tfrac{15}{16}\Delta h\right)$$

Substitute numerical values and evaluate P_P:

$$P_P = 101.325\,\text{kPa} + \left(1.00\times10^3\ \text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)\left[3.0\,\text{m} + \tfrac{15}{16}(12\,\text{m})\right] = \boxed{2.4\times10^5\,\text{Pa}}$$

67 •• Water at 20°C exits a circular tap moving straight down with a flow rate of 10.5 cm^3/s. (*a*) If the diameter of the tap is 1.20 cm, what is the speed of the water? (*b*) As the fluid falls from the tap, the stream of water narrows. Find the new diameter of the stream at a point 7.50 cm below the tap. Assume that the stream still has a circular cross section and neglect any effects of drag forces acting on the water. (*c*) If turbulent flows are characterized by Reynolds numbers above 2300 or so, how far does the water have to fall before it becomes turbulent? Does this match your everyday observations?

Picture the Problem Let I represent the flow rate of the water. Then we can use $I = Av$ to relate the flow rate to the cross-sectional area of the circular tap and the speed of the water. In (*b*) we can use the equation of continuity to express the diameter of the stream 7.50 cm below the tap and a constant-acceleration equation to find the speed of the water at this distance. In (*c*) we can use a constant-acceleration equation to express the distance-to-turbulence in terms of the speed of the water at turbulence v_t and the definition of Reynolds number N_R to relate v_t to N_R.

(*a*) Express the flow rate of the water in terms of the cross-sectional area A of the circular tap and the speed v_i of the water:

$$I = Av_i = \pi r^2 v_i = \tfrac{1}{4}\pi d^2 v_i \qquad (1)$$

Solving for v_i yields:

$$v_i = \frac{I}{\frac{1}{4}\pi d^2}$$

Substitute numerical values and evaluate v_i:

$$v_i = \frac{10.5\,\text{cm}^3/\text{s}}{\frac{1}{4}\pi(1.20\,\text{cm})^2} = \boxed{9.28\,\text{cm/s}}$$

(*b*) Apply the equation of continuity to the stream of water:

$$v_f A_f = v_i A_i$$

or

$$v_f \frac{\pi}{4} d_f^2 = v_i \frac{\pi}{4} d_i^2 \Rightarrow d_f = \sqrt{\frac{v_i}{v_f}}\, d_i \qquad (2)$$

Use a constant-acceleration equation to relate v_f and v_i to the distance Δh fallen by the water:

$$v_f^2 = v_i^2 + 2g\Delta h \Rightarrow v_f = \sqrt{v_i^2 + 2g\Delta h}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{(9.28\,\text{cm/s})^2 + 2(981\,\text{cm/s}^2)(7.50\,\text{cm})} = 122\,\text{cm/s}$$

Substitute numerical values in equation (2) and evaluate d_f:

$$d_f = (1.20\,\text{cm})\sqrt{\frac{9.28\,\text{cm/s}}{122\,\text{cm/s}}} = \boxed{0.331\,\text{cm}}$$

(*c*) Use a constant-acceleration equation to relate the fall-distance-to-turbulence Δd to its initial speed v_i and its speed v_t when its flow becomes turbulent:

$$v_t^2 = v_i^2 + 2g\Delta d \Rightarrow \Delta d = \frac{v_f^2 - v_i^2}{2g} \quad (3)$$

Express Reynolds number N_R for turbulent flow:

$$N_R = \frac{2r\rho v_t}{\eta} \quad (4)$$

The volume flow rate equals Av. Express the volume flow rate at the speed v_t:

$$I = \pi r^2 v_t \quad (5)$$

Eliminate r from equations (4) and (5) and solve for v_t (see Table 13-1 for the coefficient of viscosity for water):

$$v_t = \frac{\pi N_R^2 \eta^2}{4\rho^2 I}$$

Substitute numerical values (see Figure 13-1 for the density of water and Table 13-3 for the coefficient of viscosity for water) and evaluate v_t:

$$v_t = \frac{\pi(2300)^2\left(1.00\times10^{-3}\ \text{Pa}\cdot\text{s}\right)^2}{4\left(1.00\times10^3\ \text{kg/m}^3\right)^2\left(10.5\,\text{cm}^3/\text{s}\right)} = 0.396\,\text{m/s}$$

Substitute numerical values in equation (3) and evaluate the fall-distance-to turbulence:

$$\Delta d = \frac{(39.6\,\text{cm/s})^2 - (9.28\,\text{cm/s})^2}{2\left(9.81\,\text{m/s}^2\right)} \approx \boxed{0.76\,\text{cm}}$$

This result seems to be too small.

68 •• To better fight fires in your seaside community, the local fire brigade has asked you to set up a pump system to draw seawater from the ocean to the top of a steep cliff adjacent to the water where most of the homes are. If the cliff is 12.0 m high, and the pump is capable of producing a gauge pressure of 150 kPa, how much water (in L/s) can be pumped using a hose with a radius of 4.00 cm?

Picture the Problem The water being drawn from the ocean is at rest initially and is pumped upward to a height of 12.0 m. Let the variables subscripted 1 correspond to the intake and those subscripted 2 to the outflow and use the volume flow rate equation and Bernoulli's equation.

Express the volume flow rate in the hose:

$$I_V = Av = \pi r^2 v_2 \quad (1)$$

Apply Bernoulli's equation to the intake and outflow to obtain:

$$P_1 + \rho g h_1 + \tfrac{1}{2}\rho v_1^2 = P_2 + \rho g h_2 + \tfrac{1}{2}\rho v_2^2$$

Rewriting this equation to isolate the speed terms yields:

$$\tfrac{1}{2}\rho\left(v_2^2 - v_1^2\right) = P_1 - P_2 + \rho g h_1 - \rho g h_2$$

Because $v_1 = 0$ and $h_1 = 0$ and $P_1 - P_2 = \Delta P$:

$$\tfrac{1}{2}\rho v_2^2 = \Delta P - \rho g h_2$$

Solving for v_2 yields:

$$v_2 = \sqrt{\frac{2\left(\Delta P - \rho g h_2\right)}{\rho}}$$

Substitute for v_2 in equation (1) to obtain:

$$I_{\rm V} = \pi r^2 \sqrt{\frac{2\left(\Delta P - \rho g h_2\right)}{\rho}}$$

Substitute numerical values and evaluate $I_{\rm V}$:

$$I_{\rm V} = \pi\left(0.0400\ \text{m}\right)^2 \sqrt{\frac{2\left(150\ \text{kPa} - \left(1.00\times10^3\ \text{kg/m}^3\right)\left(9.81\ \text{m/s}^2\right)\left(12.0\ \text{m}\right)\right)}{1.00\times10^3\ \text{kg/m}^3}}$$

$$= 4.039\times10^{-2}\ \frac{\text{m}^3}{\text{s}}\times\frac{1\ \text{L}}{10^{-3}\ \text{m}^3} = \boxed{40.4\ \text{L/s}}$$

69 ••• In Figure 13-39, H is the depth of the liquid and h is the distance from the surface of the liquid to the pipe inserted in the tank's side. (*a*) Find the distance x at which the water strikes the ground as a function of h and H. (*b*) Show that, for a given value of H, there are two values of h (whose average value is $\tfrac{1}{2}H$) that give the same distance x. (*c*) Show that, for a given value of H, x is a maximum when $h = \tfrac{1}{2}H$. Find the maximum value for x as a function of H.

Picture the Problem We can apply Bernoulli's equation to points a and b to determine the rate at which the water exits the tank. Because the diameter of the small pipe is much smaller than the diameter of the tank, we can neglect the speed of the water at the point a. The distance the water travels once it exits the pipe is the product of its speed and the time required to fall the distance $H - h$. That there are two values of h that are equidistant from the point $h = \tfrac{1}{2}H$ can be shown by solving the quadratic equation that relates x to h and H. That x is a maximum for this value of h can be established by treating $x = f(h)$ as an extreme-value problem.

(*a*) Express the distance x as a function of the exit speed of the water and the time to fall the distance $H - h$:

$$x = v_b \Delta t \qquad (1)$$

Apply Bernoulli's equation to the water at points a and b:

$$P_a + \rho_{\mathrm{w}} gH + \tfrac{1}{2}\rho_{\mathrm{w}} v_a^2 = P_{\mathrm{b}} + \rho_{\mathrm{w}} g(H-h) + \tfrac{1}{2}\rho_{\mathrm{w}} v_b^2$$

or, because $v_a \approx 0$ and $P_a = P_b = P_{\mathrm{at}}$,

$$gH = g(H-h) + \tfrac{1}{2}v_b^2 \Rightarrow v_b = \sqrt{2gh}$$

Using a constant-acceleration equation, relate the time of fall to the distance of fall:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

or, because $v_{0y} = 0$,

$$H - h = \tfrac{1}{2}g(\Delta t)^2 \Rightarrow \Delta t = \sqrt{\frac{2(H-h)}{g}}$$

Substitute for Δt in equation (1) to obtain:

$$x = \sqrt{2gh}\sqrt{\frac{2(H-h)}{g}} = \boxed{2\sqrt{h(H-h)}}$$

(b) Square both sides of this equation and simplify to obtain:

$$x^2 = 4hH - 4h^2 \text{ or } 4h^2 - 4Hh + x^2 = 0$$

Solving this quadratic equation yields:

$$h = \boxed{\tfrac{1}{2}H \pm \tfrac{1}{2}\sqrt{H^2 - x^2}}$$

Find the average of these two values for h:

$$h_{\mathrm{av}} = \frac{\tfrac{1}{2}H + \sqrt{H^2 - x^2} + \tfrac{1}{2}H - \sqrt{H^2 - x^2}}{2} = \boxed{\tfrac{1}{2}H}$$

(c) Differentiate $x = 2\sqrt{h(H-h)}$ with respect to h:

$$\frac{dx}{dh} = 2\left(\tfrac{1}{2}\right)[h(H-h)]^{-\frac{1}{2}}(H-2h) = \frac{H-2h}{\sqrt{h(H-h)}}$$

Set dx/dh equal to zero for extrema:

$$\frac{H-2h}{\sqrt{h(H-h)}} = 0$$

Solve for h to obtain:

$$h = \boxed{\tfrac{1}{2}H}$$

Evaluate $x = 2\sqrt{h(H-h)}$ with $h = \tfrac{1}{2}H$:

$$x_{\max} = 2\sqrt{\tfrac{1}{2}H\left(H - \tfrac{1}{2}H\right)} = \boxed{H}$$

Remarks: To show that this value for *h* corresponds to a *maximum*, one can either show that $\frac{d^2x}{dh^2} < 0$ at $h = \frac{1}{2}H$ or confirm that the graph of *f*(*h*) at $h = \frac{1}{2}H$ is concave downward.

*Viscous Flow

70 • Water flows through a horizontal 25.0-cm-long tube with an inside diameter of 1.20 mm at 0.300 mL/s. Find the pressure difference required to drive this flow if the viscosity of water is 1.00 mPa·s. Assume laminar flow.

Picture the Problem The required pressure difference can be found by applying Poiseuille's law to the viscous flow of water through the horizontal tube.

Using Poiseuille's law, relate the pressure difference between the two ends of the tube to its length, radius, and the volume flow rate of the water:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_\text{V}$$

Substitute numerical values and evaluate ΔP:

$$\Delta P = \frac{8(1.00\,\text{mPa}\cdot\text{s})(0.250\,\text{m})}{\pi\left(\dfrac{1.20\times10^{-3}\,\text{m}}{2}\right)^4}(0.300\,\text{mL/s}) = \boxed{1.47\,\text{kPa}}$$

71 • Find the diameter of a tube that would give double the flow rate for the pressure difference in Problem 70.

Picture the Problem Because the pressure difference is unchanged, we can equate the expressions of Poiseuille's law for the two tubes and solve for the diameter of the tube that would double the flow rate.

Using Poiseuille's law, express the pressure difference required for the radius and volume flow rate of Problem 70:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_\text{V}$$

Express the pressure difference required for the radius r' that would double the volume flow rate of Problem 70:

$$\Delta P = \frac{8\eta L}{\pi r'^4}(2I_\text{V})$$

Equate these equations and simplify to obtain:

$$\frac{8\eta L}{\pi r'^4}(2I_\text{V})=\frac{8\eta L}{\pi r^4}I_\text{V}$$

or

$$\frac{2}{r'^4}=\frac{1}{r^4}\Rightarrow r'=\sqrt[4]{2}r$$

Because d' is two times r':

$$d'=2r'=2\sqrt[4]{2}r=\sqrt[4]{2}d$$

Substitute numerical values and evaluate d':

$$d'=\sqrt[4]{2}(1.20\,\text{mm})=\boxed{1.43\,\text{mm}}$$

72 • Blood takes about 1.00 s to pass through a 1.00-mm-long capillary in the human circulatory system. If the diameter of the capillary is 7.00 μm and the pressure drop is 2.60 kPa, find the viscosity of blood. Assume laminar flow.

Picture the Problem We can apply Poiseuille's law to relate the pressure drop across the capillary tube to the radius and length of the tube, the rate at which blood is flowing through it, and the viscosity of blood.

Using Poiseuille's law, relate the pressure drop to the length and diameter of the capillary tube, the volume flow rate of the blood, and the viscosity of the blood:

$$\Delta P=\frac{8\eta L}{\pi r^4}I_\text{V}\Rightarrow\eta=\frac{\pi r^4\Delta P}{8LI_\text{V}}$$

Using its definition, express the volume flow rate of the blood:

$$I_\text{V}=A_\text{cap}v=\pi r^2v$$

Substitute for I_V and simplify to obtain:

$$\eta=\frac{r^2\Delta P}{8Lv}$$

Substitute numerical values to obtain:

$$\eta=\frac{(3.50\times10^{-6}\,\text{m})^2(2.60\,\text{kPa})}{8(1.00\times10^{-3}\,\text{m})\left(\dfrac{1.00\times10^{-3}\,\text{m}}{1.00\,\text{s}}\right)}$$

$$=\boxed{3.98\,\text{mPa}\cdot\text{s}}$$

73 • **[SSM]** An abrupt transition occurs at Reynolds numbers of about 3×10^5, where the drag on a sphere moving through a fluid abruptly decreases. Estimate the speed at which this transition occurs for a baseball, and comment on whether it should play a role in the physics of the game.

Picture the Problem We can use the definition of Reynolds number to find the speed of a baseball at which the drag crisis occurs.

Using its definition, relate Reynolds number to the speed v of the baseball:

$$N_R = \frac{2r\rho v}{\eta} \Rightarrow v = \frac{\eta N_R}{2r\rho}$$

Substitute numerical values (see Figure 13-1 for the density of air and Table 13-3 for the coefficient of viscosity for air) and evaluate v:

$$v = \frac{(0.018\,\text{mPa}\cdot\text{s})(3\times10^5)}{2(0.05\,\text{m})(1.293\,\text{kg/m}^3)} = 41.8\,\text{m/s}\times\frac{1\,\text{mi/h}}{0.447\,\text{m/s}} \approx \boxed{90\,\text{mi/h}}$$

Because most major league pitchers can throw a fastball in the low-to-mid-90s, this drag crisis may very well play a role in the game.

Remarks: This is a topic that has been fiercely debated by people who study the physics of baseball.

74 •• A horizontal pipe of radius 1.5 cm and length 25 m is connected to the output that can sustain an output gauge pressure of 10 kPa. What is the speed of 20°C water flowing through the pipe? If the temperature of the water is 60°C, what is the speed of the water in the pipe?

Picture the Problem Assuming laminar flow of the water, we can apply Poiseuille's law to find the speed of the water coming out the outflow end of the pipe.

Use Poiseuille's law to relate the pressure difference to the volume flow rate in the pipe:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_V$$

Substituting for I_V yields:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_V = \frac{8\eta L}{\pi r^4} Av$$

Substitute for the cross-sectional area A of the pipe and simplify to obtain:

$$\Delta P = \frac{8\eta L}{\pi r^4}\pi r^2 v = \frac{8\eta L}{r^2} v$$

Solving for v yields:

$$v = \frac{r^2 \Delta P}{8\eta L}$$

Substitute numerical values and evaluate v(20°C):

$$v(20°\text{C}) = \frac{(0.015\,\text{m})^2(10\,\text{kPa})}{8(1.00\,\text{mPa}\cdot\text{s})(25\,\text{m})} = \boxed{11\,\text{m/s}}$$

Substitute numerical values and evaluate $v(60°\text{C})$:

$$v(60°\text{C}) = \frac{(0.015\ \text{m})^2(10\ \text{kPa})}{8(0.65\ \text{mPa}\cdot\text{s})(25\ \text{m})} = \boxed{17\ \text{m/s}}$$

75 •• A very large tank is filled to a depth of 250 cm with oil that has a density of 860 kg/m^3 and a viscosity of 180 mPa·s. If the container walls are 5.00 cm thick, and a cylindrical hole of radius 0.750 cm is bored through the base of the container, what is the initial volume flow rate (in L/s) of the oil through the hole?

Picture the Problem Assuming laminar flow, we can apply Poiseuille's law to relate the pressure difference between the inside and the outside of the container at its base to the volume flow rate of oil out of the hole. We can find the pressure difference from the expression for the pressure as a function of depth in a fluid.

Use Poiseuille's law to relate the pressure difference to the volume flow rate of oil out of the hole:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_\text{V} \Rightarrow I_\text{V} = \frac{\pi r^4 \Delta P}{8\eta L} \quad (1)$$

The pressure at the bottom of the container of oil is given by:

$$P = P_0 + \rho_\text{oil} g h$$

The pressure difference between the inside and outside of the container is:

$$\Delta P = P - P_0 = \rho_\text{oil} g h$$

Substituting for ΔP in equation (1) yields:

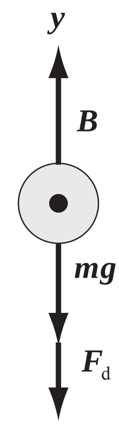
$$I_\text{V} = \frac{\pi r^4 \rho_\text{oil} g h}{8\eta L}$$

Substitute numerical values and evaluate I_V:

$$I_\text{V} = \frac{\pi(0.0075\ \text{m})^4(860\ \text{kg/m}^3)(9.81\ \text{m/s}^2)(2.50\ \text{m})}{8(180\ \text{mPa}\cdot\text{s})(0.0500\ \text{m})} = 2.91\times10^{-3}\ \text{m}^3/\text{s} = \boxed{2.91\ \text{L/s}}$$

76 ••• The drag force on a moving sphere at very low Reynolds number is given by $F_\text{D} = 6\pi\eta a v$, where η is the viscosity of the surrounding fluid and a is the radius of the sphere. (This relation is called Stokes' law.) Using this information, find the terminal speed of ascent for a spherical 1.0-mm diameter carbon dioxide bubble of 1.0-mm diameter rising in a carbonated beverage (ρ = 1.1 kg/L and η = 1.8 mPa·s). How long should it take for this bubble to rise 20 cm (the height of a drinking glass)? Is this length of time consistent with your observations?

Picture the Problem Let the subscripts ″f″ refer to ″displaced fluid", ″s″ to ″soda″, and ″g″ to the ″gas″ in the bubble. The free-body diagram shows the forces acting on the bubble prior to reaching its terminal speed. We can apply Newton's second law, Stokes′ law, and Archimedes principle to express the terminal speed of the bubble in terms of its radius, and the viscosity and density of water.



Apply $\sum F_y = ma_y$ to the bubble to obtain:

$$B - m_g g - F_D = ma_y$$

Under terminal speed conditions:

$$B - m_g g - F_D = 0$$

Using Archimedes principle, express the buoyant force B acting on the bubble:

$$B = w_f = m_f g = \rho_f V_f g = \rho_s V_{bubble} g$$

Express the mass of the gas bubble:

$$m_g = \rho_g V_g = \rho_g V_{bubble}$$

Substitute to obtain:

$$\rho_s V_{bubble} g - \rho_g V_{bubble} g - 6\pi\eta a v_t = 0$$

Solving for v_t gives:

$$v_t = \frac{V_{bubble} g(\rho_s - \rho_g)}{6\pi\eta a}$$

Substitute for V_{bubble} and simplify:

$$v_t = \frac{\frac{4}{3}\pi a^3 g(\rho_s - \rho_g)}{6\pi\eta a} = \frac{2a^2 g(\rho_s - \rho_g)}{9\eta} \approx \frac{2a^2 g\rho_s}{9\eta}, \text{since } \rho_s >> \rho_g.$$

Substitute numerical values and evaluate v_t:

$$v_t = \frac{2(0.50\times10^{-3}\text{ m})^2(9.81\text{m/s}^2)(1.1\times10^3\text{ kg/m}^3)}{9(1.8\times10^{-3}\text{ Pa}\cdot\text{s})} = 0.333\text{m/s} = \boxed{0.33\text{m/s}}$$

Express the rise time Δt in terms of the height of the soda glass h and the terminal speed of the bubble:

$$\Delta t = \frac{h}{v_t}$$

Assuming that a "typical" soda glass has a height of about 15 cm, evaluate Δt:

$$\Delta t = \frac{0.15\,\text{m}}{0.333\,\text{m/s}} = \boxed{0.45\,\text{s}}$$

Remarks: About half a second seems reasonable for the rise time of the bubble.

General Problems

77 • **[SSM]** Several teenagers swim toward a rectangular, wooden raft that is 3.00 m wide and 2.00 m long. If the raft is 9.00 cm thick, how many 75.0-kg teenage boys can stand on top of the raft without the raft becoming submerged? Assume the wood density is 650 kg/m^3.

Picture the Problem If the raft is to be just barely submerged, then the buoyant force on it will be equal in magnitude to the weight of the raft plus the weight of the boys. We can apply Archimedes' principle to find the buoyant force on the raft.

The buoyant force acting on the raft is the sum of the weights of the raft and the boys:

$$B = w_{\text{raft}} + w_{\text{boys}} \qquad (1)$$

Express the buoyant force acting on the raft:

$$B = w_{\text{displaced water}} = m_{\text{displaced water}}\,g = \rho_{\text{water}} V_{\text{displaced water}}\,g = \rho_{\text{water}} V_{\text{raft}}\,g$$

Express the weight of the raft:

$$w_{\text{raft}} = m_{\text{raft}}\,g = \rho_{\text{raft}} V_{\text{raft}}\,g$$

Express the weight of the boys:

$$w_{\text{boys}} = m_{\text{boys}}\,g = N m_{1\,\text{boy}}\,g$$

Substituting for B, w_{raft}, and w_{boys} in equation (1) yields:

$$\rho_{\text{water}} V_{\text{raft}}\,g = \rho_{\text{raft}} V_{\text{raft}}\,g + N m_{1\,\text{boy}}\,g$$

Solve for N and simplify to obtain:

$$N = \frac{\rho_{\text{water}} V_{\text{raft}}\,g - \rho_{\text{raft}} V_{\text{raft}}\,g}{m_{1\,\text{boy}}\,g} = \frac{(\rho_{\text{water}} - \rho_{\text{raft}})V_{\text{raft}}}{m_{1\,\text{boy}}}$$

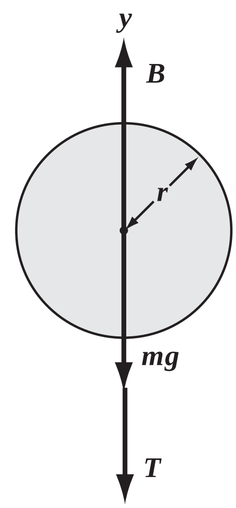
Substitute numerical values and evaluate N:

$$N = \frac{\left(1.00\times10^{3}\ \text{kg/m}^3 - 650\,\text{kg/m}^3\right)(3.00\,\text{m})(2.00\,\text{m})(0.0900\,\text{m})}{75.0\,\text{kg}} = 2.52$$

Hence, a maximum of $\boxed{2}$ boys can be on the raft under these circumstances.

78 • A thread attaches a 2.7-g Ping-Pong ball to the bottom of a beaker. When the beaker is filled with water so that the ball is totally submerged, the tension in the thread is 7.0 mN. Determine the diameter of the ball.

Picture the Problem The forces acting on the ball, shown in the free-body diagram, are the buoyant force, the weight of the ball, and the tension in the string. Because the ball is in equilibrium under the influence of these forces, we can apply the condition for translational equilibrium to establish the relationship between them. We can also apply Archimedes' principle to relate the buoyant force on the ball to its diameter.



Apply $\sum F_y = 0$ to the ball:

$$B - mg - T = 0$$

Using Archimedes' principle, relate the buoyant force on the ball to its diameter:

$$B = w_{\substack{\text{displaced}\\ \text{water}}} = m_{\substack{\text{displaced}\\ \text{water}}} g = \rho_{\text{water}} V_{\text{ball}} g = \tfrac{4}{3}\pi\rho_{\text{water}} g r^3$$

Substituting for B yields:

$$\tfrac{4}{3}\pi\rho_{\text{water}} g r^3 - mg - T = 0$$

Solve for r:

$$r = \sqrt[3]{\frac{3(T+mg)}{4\pi\rho_{\text{water}} g}} \Rightarrow d = 2\left(\sqrt[3]{\frac{3(T+mg)}{4\pi\rho_{\text{water}} g}}\right)$$

Substitute numerical values and evaluate d:

$$d = 2\left(\sqrt[3]{\frac{3\left[7.0\ \text{mN} + (0.0027\,\text{kg})(9.81\,\text{m/s}^2)\right]}{4\pi(1.00\times10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)}}\right) = \boxed{1.9\,\text{cm}}$$

79 • Seawater has a bulk modulus of 2.30×10^9 N/m^2. Find the difference in density of seawater at a depth where the pressure is 800 atm as compared to the density at the surface which is 1025 kg/m^3. Neglect any effects due to either temperature or salinity.

Picture the Problem Let ρ_0 represent the density of seawater at the surface. We can use the definition of density and the fact that mass is constant to relate the fractional change in the density of water to its fractional change in volume. We can also use the definition of bulk modulus to relate the fractional change in density to the increase in pressure with depth and solve the resulting equation for the change in density at the depth at which the pressure is 800 atm.

Using the definition of density, relate the mass of a given volume of seawater to its volume:

$$m = \rho V$$

Noting that the mass does not vary with depth, evaluate its differential:

$$\rho dV + V d\rho = 0$$

Solve for $d\rho/\rho$:

$$\frac{d\rho}{\rho} = -\frac{dV}{V} \text{ or } \frac{\Delta\rho}{\rho} \approx -\frac{\Delta V}{V}$$

Using the definition of the bulk modulus, relate ΔP to $\Delta\rho/\rho_0$:

$$B = -\frac{\Delta P}{\Delta V/V} = \frac{\Delta P}{\Delta\rho/\rho_0}$$

Solving for $\Delta\rho$ yields:

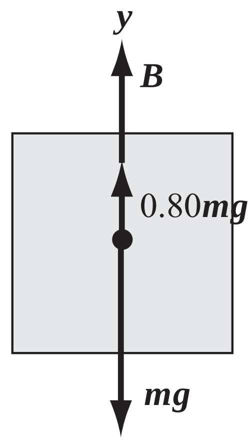
$$\Delta\rho = \rho - \rho_0 = \frac{\rho_0 \Delta P}{B}$$

Substitute numerical values and evaluate $\Delta\rho$:

$$\Delta\rho = \frac{\left(1025\,\text{kg/m}^3\right)\left(799\,\text{atm} \times \dfrac{101.325\,\text{kPa}}{1\,\text{atm}}\right)}{2.30\times10^9\ \text{N/m}^2} = \boxed{36.1\ \text{kg/m}^3}$$

80 • A solid cube with 0.60-m edge length is suspended from a spring balance. When the cube is submerged in water, the spring balance reads 80 percent of the reading when the cube is in air. Determine the density of the cube.

Picture the Problem When it is submerged, the block is in equilibrium under the influence of the buoyant force due to the water, the force exerted by the spring balance, and its weight. We can use the condition for translational equilibrium to relate the buoyant force to the weight of the block and the definition of density to express the weight of the block in terms of its density.



Apply $\sum F_y = 0$ to the block:

$$B + 0.80mg - mg = 0 \Rightarrow B = 0.20mg$$

Substitute for B and m to obtain:

$$\rho_{\text{w}} V_{\text{block}} g = 0.20 \rho_{\text{block}} V_{\text{block}} g$$

Solve for and evaluate ρ_{block}:

$$\rho_{\text{block}} = \frac{\rho_{\text{w}}}{0.20} = 5.0\left(1.00\times10^3\ \text{kg/m}^3\right) = \boxed{5.0\times10^3\ \text{kg/m}^3}$$

81 •• [SSM] A 1.5-kg block of wood floats on water with 68 percent of its volume submerged. A lead block is placed on the wood, fully submerging the wood to a depth where the lead remains entirely out of the water. Find the mass of the lead block.

Picture the Problem Let m and V represent the mass and volume of the block of wood. Because the block is in equilibrium when it is floating, we can apply the condition for translational equilibrium and Archimedes' principle to express the dependence of the volume of water it displaces when it is fully submerged on its weight. We'll repeat this process for the situation in which the lead block is resting on the wood block with the latter fully submerged. Let the upward direction be the $+y$ direction.

Apply $\sum F_y = 0$ to floating block:

$$B - mg = 0 \qquad (1)$$

Use Archimedes' principle to relate the density of water to the volume of the block of wood:

$$B = w_{\substack{\text{displaced}\\ \text{water}}} = m_{\substack{\text{displaced}\\ \text{water}}} g = \rho_{\text{water}} V_{\substack{\text{displaced}\\ \text{water}}} g = \rho_{\text{water}}\left(0.68V\right)g$$

Using the definition of density, express the weight of the block in terms of its density:

$$mg = \rho_{\text{wood}} V g$$

Substitute for B and mg in equation (1) to obtain:

$$\rho_{\text{water}}(0.68V)g - \rho_{\text{wood}}Vg = 0$$

Solving for ρ_{wood} yields:

$$\rho_{\text{wood}} = 0.68\rho_{\text{water}}$$

Use the definition of density to express the volume of the wood:

$$V = \frac{m}{\rho_{\text{wood}}}$$

Apply $\sum F_y = 0$ to the floating block when the lead block is placed on it:

$B' - m'g = 0$, where B' is the new buoyant force on the block and m' is the combined mass of the wood block and the lead block.

Use Archimedes' principle and the definition of density to obtain:

$$\rho_{\text{water}}Vg - (m_{\text{Pb}} + m)g = 0$$

Solve for the mass of the lead block to obtain:

$$m_{\text{Pb}} = \rho_{\text{water}}V - m$$

Substituting for V and ρ_{water} yields:

$$m_{\text{Pb}} = \frac{\rho_{\text{wood}}}{0.68}\frac{m}{\rho_{\text{wood}}} - m = \left(\frac{1}{0.68} - 1\right)m$$

Substitute numerical values and evaluate m_{Pb}:

$$m_{\text{Pb}} = \left(\frac{1}{0.68} - 1\right)(1.5\text{ kg}) = \boxed{0.71\text{ kg}}$$

82 •• A Styrofoam cube, 25 cm on an edge, is placed on one pan of a balance. The balance is in equilibrium when a 20-g mass of brass is placed on the other pan. Find the mass of the Styrofoam cube. Neglect the buoyant force of the air on the brass mass, but do not neglect the buoyant force of the air on the Styrofoam cube.

Picture the Problem The true mass of the Styrofoam cube is greater than that indicated by the balance due to the buoyant force acting on it. The balance is in rotational equilibrium under the influence of the buoyant and gravitational forces acting on the Styrofoam cube and the brass masses. Let m and V represent the mass and volume of the cube and L the lever arm of the balance.

Apply $\sum \vec{\tau} = 0$ to the balance:

$$(mg - B)L - m_{\text{brass}}gL = 0 \qquad (1)$$

Use Archimedes' principle to express the buoyant force on the Styrofoam cube as a function of volume and density of the air it displaces:

$$B = w_{\substack{\text{displaced}\\ \text{fluid}}} = m_{\substack{\text{displaced}\\ \text{fluid}}}\, g = \rho_{\substack{\text{displaced}\\ \text{fluid}}} V_{\substack{\text{displaced}\\ \text{fluid}}}\, g = \rho_{\text{air}} V g$$

Substitute for B in equation (1) and simplify to obtain:

$$m - \rho_{\text{air}} V - m_{\text{brass}} = 0$$

Solving for m yields:

$$m = \rho_{\text{air}} V + m_{\text{brass}}$$

Substitute numerical values and evaluate m:

$$m = \left(1.293\,\text{kg/m}^3\right)\left(0.25\,\text{m}\right)^3 + 20\times10^{-3}\,\text{kg} = \boxed{40\,\text{g}}$$

83 •• A spherical shell of copper with an outer diameter of 12.0 cm floats on water with half its volume above the water's surface. Determine the inner diameter of the shell. The cavity inside the spherical shell is empty.

Picture the Problem Let d_{in} and d_{out} represent the inner and outer diameters of the copper shell and V' the volume of the spherical shell that is submerged. Because the spherical shell is floating, it is in equilibrium and we can apply a condition for translational equilibrium to relate the buoyant force B due to the displaced water and its weight w.

Apply $\sum F_y = 0$ to the spherical shell:

$$B - w = 0$$

Using Archimedes' principle and the definition of w, substitute to obtain:

$$\rho_{\text{w}} V' g - mg = 0 \Rightarrow \rho_{\text{w}} V' - m = 0 \quad (1)$$

Express V' as a function d_{out}:

$$V' = \frac{1}{2}\frac{\pi}{6} d_{\text{out}}^3 = \frac{\pi}{12} d_{\text{out}}^3$$

Express m in terms of d_{in} and d_{out}:

$$m = \rho_{\text{Cu}}\left(V_{\text{out}} - V_{\text{in}}\right) = \rho_{\text{Cu}}\left(\frac{\pi}{6} d_{\text{out}}^3 - \frac{\pi}{6} d_{\text{in}}^3\right)$$

Substitute in equation (1) to obtain:

$$\rho_{\text{w}} \frac{\pi}{12} d_{\text{out}}^3 - \rho_{\text{Cu}}\left(\frac{\pi}{6} d_{\text{out}}^3 - \frac{\pi}{6} d_{\text{in}}^3\right) = 0$$

Simplifying yields:

$$\frac{1}{2}\rho_{\rm w}d_{\rm out}^3-\rho_{\rm Cu}\left(d_{\rm out}^3-d_{\rm in}^3\right)=0$$

Solve for $d_{\rm in}$ to obtain:

$$d_{\rm in}=d_{\rm out}\sqrt[3]{1-\frac{\rho_{\rm w}}{2\rho_{\rm Cu}}}$$

Substitute numerical values and evaluate $d_{\rm in}$:

$$d_{\rm in}=(12.0\,{\rm cm})\sqrt[3]{1-\frac{1}{2(8.93)}}=\boxed{11.8\,{\rm cm}}$$

84 •• A 200-mL beaker that is half-filled with water is on the left pan of a balance, and a sufficient amount of sand is placed on the right pan to bring the balance to equilibrium. A cube 4.0 cm on an edge that is attached to a string is then lowered into the water so that it is completely submerged, but not touching the bottom of the beaker. A piece of brass of mass m is then added to the right pan to restore equilibrium. What is m?

Determine the Concept Taking the water in the beaker and the beaker as the system, the additional weight on the right pan is needed to balance the reaction force to the buoyant force the water in the beaker exerts on the cube.

The buoyant force exerted on the cube by the water is given by:

$$B=w_{\rm displaced\ water}=m_{\rm water}g=\rho_{\rm water}V_{\rm cube}g$$

The weight of the piece of brass is the product of its mass and the gravitational field:

$$w=mg$$

Equating these forces yields:

$$\rho_{\rm water}V_{\rm cube}g=mg\Rightarrow m=\rho_{\rm water}V_{\rm cube}$$

Substitute numerical values and evaluate m:

$$m=\left(1.00\ {\rm g/cm^3}\right)(4\ {\rm cm})^3=\boxed{64\ {\rm g}}$$

85 •• **[SSM]** Crude oil has a viscosity of about 0.800 Pa·s at normal temperature. You are the chief design engineer in charge of constructing a 50.0-km horizontal pipeline that connects an oil field to a tanker terminal. The pipeline is to deliver oil at the terminal at a rate of 500 L/s and the flow through the pipeline is to be laminar. Assuming that the density of crude oil is 700 kg/m^3, estimate the diameter of the pipeline that should be used.

Picture the Problem We can use the definition of Reynolds number and assume a value for N_R of 1000 (well within the laminar-flow range) to obtain a trial value for the radius of the pipe. We'll then use Poiseuille's law to determine the pressure difference between the ends of the pipe that would be required to maintain a volume flow rate of 500 L/s.

Use the definition of Reynolds number to relate N_R to the radius of the pipe:

$$N_R = \frac{2r\rho v}{\eta}$$

Use the definition of I_V to relate the volume flow rate of the pipe to its radius:

$$I_V = Av = \pi r^2 v \Rightarrow v = \frac{I_V}{\pi r^2}$$

Substitute to obtain:

$$N_R = \frac{2\rho I_V}{\eta\pi r} \Rightarrow r = \frac{2\rho I_V}{\eta\pi N_R}$$

Substitute numerical values and evaluate r:

$$r = \frac{2(700\,\text{kg/m}^3)(0.500\,\text{m}^3/\text{s})}{\pi(0.800\,\text{Pa}\cdot\text{s})(1000)} = 27.9\,\text{cm}$$

Using Poiseuille's law, relate the pressure difference between the ends of the pipe to its radius:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_V$$

Substitute numerical values and evaluate ΔP:

$$\Delta P = \frac{8(0.800\,\text{Pa}\cdot\text{s})(50\,\text{km})}{\pi(0.279\,\text{m})^4}(0.500\text{m}^3/\text{s})$$
$$= 8.41\times10^6\ \text{Pa} = 83.0\,\text{atm}$$

This pressure is too large to maintain in the pipe. Evaluate ΔP for a pipe of 50 cm radius:

$$\Delta P = \frac{8(0.800\,\text{Pa}\cdot\text{s})(50\,\text{km})}{\pi(0.50\,\text{m})^4}(0.500\,\text{m}^3/\text{s})$$
$$= 8.15\times10^5\ \text{Pa} = 8.04\,\text{atm}$$

1 m is a reasonable diameter for the pipeline. This larger diameter makes the Reynolds number still smaller, so the flow is still laminar.

86 •• Water flows through the pipe in Figure 13-40 and exits to the atmosphere at the right end of section C. The diameter of the pipe is 2.00 cm at A, 1.00 cm at B, and 0.800 cm at C. The gauge pressure in the pipe at the center of section A is 1.22 atm and the flow rate is 0.800 L/s. The vertical pipes are open to the air. Find the level (above the flow mid-line as shown) of the liquid–air interfaces in the two vertical pipes. Assume laminar nonviscous flow.

Picture the Problem We'll measure the height of the liquid–air interfaces relative to the centerline of the pipe. We can use the definition of the volume flow rate in a pipe to find the speed of the water at point A and the relationship between the gauge pressures at points A and C to determine the level of the liquid-air interface at A. We can use the continuity equation to express the speed of the water at B in terms of its speed at A and Bernoulli's equation for constant elevation to find the gauge pressure at B. Finally, we can use the relationship between the gauge pressures at points A and B to find the level of the liquid-air interface at B.

Relate the gauge pressure in the pipe at A to the height of the liquid-air interface at A:

$$P_{\text{gauge,A}} = \rho g h_{\text{A}} \Rightarrow h_{\text{A}} = \frac{P_{\text{gauge,A}}}{\rho g}$$

where h_{A} is measured from the center of the pipe.

Substitute numerical values and evaluate h_{A}:

$$h_{\text{A}} = \frac{(1.22\,\text{atm})(1.01\times10^5\ \text{Pa/atm})}{(1.00\times10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)} = \boxed{12.6\,\text{m}}$$

Determine the speed of the water at A:

$$v_{\text{A}} = \frac{I_{\text{V}}}{A_{\text{A}}} = \frac{0.800\times10^{-3}\ \text{m}^3/\text{s}}{\frac{\pi}{4}(0.0200\,\text{m})^2} = 2.55\,\text{m/s}$$

Apply Bernoulli's equation for constant elevation to relate P_{B} and P_{A}:

$$P_{\text{A}} + \tfrac{1}{2}\rho v_{\text{A}}^2 = P_{\text{B}} + \tfrac{1}{2}\rho v_{\text{B}}^2 \qquad (1)$$

Use the continuity equation to relate v_{B} and v_{A}:

$$A_{\text{A}} v_{\text{A}} = A_{\text{B}} v_{\text{B}} \Rightarrow v_{\text{B}} = \frac{A_{\text{A}}}{A_{\text{B}}} v_{\text{A}}$$

Substitute numerical values and evaluate v_{B}:

$$v_{\text{B}} = \frac{(2.00\,\text{cm})^2}{(1.00\,\text{cm})^2} v_{\text{A}} = 4 v_{\text{A}}$$

Substitute in equation (1) to obtain:

$$P_{\text{A}} + \tfrac{1}{2}\rho v_{\text{A}}^2 = P_{\text{B}} + 8\rho v_{\text{A}}^2$$

Solving for P_{B} yields:

$$P_{\text{B}} = P_{\text{A}} - \tfrac{15}{2}\rho v_{\text{A}}^2 = P_{\text{gauge, A}} + P_{\text{at}} - \tfrac{15}{2}\rho v_{\text{A}}^2$$

Substitute numerical values and evaluate P_B:

$$P_B = (1.22\,\text{atm} + 1.00\,\text{atm})(101.325\,\text{kPa/atm}) - \tfrac{15}{2}(1.00\times10^3\ \text{kg/m}^3)(2.55\,\text{m/s})^2$$
$$= 1.762\times10^5\ \text{Pa}\times\frac{1\,\text{atm}}{101.325\,\text{kPa}} = 1.739\,\text{atm}$$

Relate the gauge pressure in the pipe at B to the height of the liquid-air interface at B:

$$P_{\text{gauge,B}} = \rho g h_B$$

Solve for h_B:

$$h_B = \frac{P_{\text{gauge,B}}}{\rho g} = \frac{P_B - P_{\text{at}}}{\rho g}$$

Substitute numerical values and evaluate h_B:

$$h_B = \frac{(1.739\,\text{atm} - 1.00\,\text{atm})\left(101.325\dfrac{\text{kPa}}{\text{atm}}\right)}{(1.00\times10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)} = \boxed{7.63\,\text{m}}$$

87 •• [SSM] You are employed as a tanker truck driver for the summer. Heating oil is delivered to customers for winter usage by your large tanker truck. The delivery hose has a radius 1.00 cm. The specific gravity of the oil is 0.875, and its coefficient of viscosity is 200 mPa·s. What is the minimum time it will take you fill a customer's 55-gal oil drum if laminar flow through the hose must be maintained?

Picture the Problem We can use the volume of the drum and the volume flow rate equation to express the time to fill the customer's oil drum. The Reynolds number equation relates Reynolds number to the speed with which oil flows through the hose to the volume flow rate. Because the upper limit on the Reynolds number for laminar flow is approximately 2000, we'll use this value in our calculation of the fill time.

The time t_{fill} is related to the volume flow rate in the hose:

$$t_{\text{fill}} = \frac{V}{I_V} = \frac{V}{Av} \qquad (1)$$

where A is the cross-sectional area of the hose and V is the volume of the oil drum.

Reynolds number is defined by the equation:

$$N_R = \frac{2r\rho v}{\eta} \Rightarrow v = \frac{\eta N_R}{2r\rho}$$

Substitute for v and A in equation (1) to obtain:

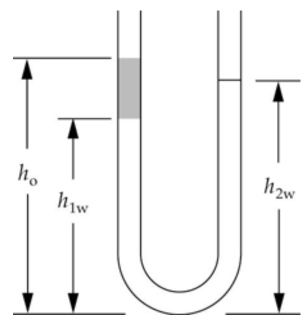
$$t_{\text{fill}} = \frac{V}{\pi r^2\left(\frac{\eta N_{\text{R}}}{2r\rho}\right)} = \frac{2\rho V}{\pi r\eta N_{\text{R}}}$$

Substitute numerical values and evaluate t_{fill}:

$$t_{\text{fill}} = \frac{2\left(875\ \text{kg/m}^3\right)\left(55\ \text{gal}\times\frac{3.785\ \text{L}}{\text{gal}}\right)}{\pi(0.010\ \text{m})(200\ \text{mPa}\cdot\text{s})(2000)} = \boxed{29\ \text{s}}$$

88 •• A U-tube is filled with water until the liquid level is 28 cm above the bottom of the tube (Figure 13-41*a*). Oil, which has a specific gravity 0.78, is now poured into one arm of the U-tube until the level of the water in the other arm of the tube is 34 cm above the bottom of the tube (Figure 13-41*b*). Find the levels of the oil–water and oil–air interfaces in the other arm of the tube.

Picture the Problem We can use the equality of the pressure at the bottom of the U-tube due to the water on one side and that due to the oil and water on the other to relate the various heights. Let h represent the height of the oil above the water. Then $h_{\text{o}} = h_{1\text{w}} + h$.



Using the constancy of the amount of water, express the relationship between $h_{1\text{w}}$ and $h_{2\text{w}}$:

$$h_{1\text{w}} + h_{2\text{w}} = 56\ \text{cm}$$

Find the height of the oil-water interface:

$$h_{1\text{w}} = 56\,\text{cm} - 34\,\text{cm} = \boxed{22\,\text{cm}}$$

Express the equality of the pressure at the bottom of the two arms of the U tube:

$$\rho_{\text{w}} g(34\,\text{cm}) = \rho_{\text{w}} g(22\,\text{cm}) + 0.78\rho_{\text{w}} g h_{\text{oil}}$$

Solve for and evaluate h_{oil}:

$$h_{\text{oil}} = \frac{\rho_{\text{w}} g(34\,\text{cm}) - \rho_{\text{w}} g(22\,\text{cm})}{0.78\rho_{\text{w}} g} = \frac{(34\,\text{cm}) - (22\,\text{cm})}{0.78} = 15.4\,\text{cm}$$

The height of the air-oil interface h_{o} is:

$$h_{\text{o}} = 22\text{cm} + 15.4\,\text{cm} = \boxed{37\,\text{cm}}$$

89 •• [SSM] A helium balloon can just lift a load that weighs 750 N and has a negligible volume. The skin of the balloon has a mass of 1.5 kg. (*a*) What is the volume of the balloon? (*b*) If the volume of the balloon were twice that found in Part (*a*), what would be the initial acceleration of the balloon when released at sea level carrying a load weighing 900 N?

Picture the Problem The balloon is in equilibrium under the influence of the buoyant force exerted by the air, the weight of its basket and load *w*, the weight of the skin of the balloon, and the weight of the helium. Choose upward to be the +*y* direction and apply the condition for translational equilibrium to relate these forces. Archimedes' principle relates the buoyant force on the balloon to the density of the air it displaces and the volume of the balloon.

(*a*) Apply $\sum F_y = 0$ to the balloon:

$$B - m_{\text{skin}}g - m_{\text{He}}g - w = 0$$

Letting *V* represent the volume of the balloon, use Archimedes' principle to express the buoyant force:

$$\rho_{\text{air}}Vg - m_{\text{skin}}g - m_{\text{He}}g - w = 0$$

Substituting for m_{He} yields:

$$\rho_{\text{air}}Vg - m_{\text{skin}}g - \rho_{\text{He}}Vg - w = 0$$

Solve for *V* to obtain:

$$V = \frac{m_{\text{skin}}g + w}{(\rho_{\text{air}} - \rho_{\text{He}})g}$$

Substitute numerical values and evaluate *V*:

$$V = \frac{(1.5\,\text{kg})(9.81\,\text{m/s}^2) + 750\,\text{N}}{(1.293\,\text{kg/m}^3 - 0.1786\,\text{kg/m}^3)(9.81\,\text{m/s}^2)} = \boxed{70\,\text{m}^3}$$

(*b*) Apply $\sum F_y = ma$ to the balloon:

$$B - m_{\text{tot}}g = m_{\text{tot}}a \Rightarrow a = \frac{B}{m_{\text{tot}}} - g \quad (1)$$

Assuming that the mass of the skin has not changed and letting *V'* represent the doubled volume of the balloon, express m_{tot}:

$$m_{\text{tot}} = m_{\text{load}} + m_{\text{He}} + m_{\text{skin}} = \frac{w_{\text{load}}}{g} + \rho_{\text{He}}V' + m_{\text{skin}}$$

Express the buoyant force acting on the balloon:

$$B = w_{\text{displaced fluid}} = \rho_{\text{air}}V'g$$

Substituting for m_{tot} and B in equation (1) yields:

$$a = \frac{\rho_{air} V' g}{\frac{w_{load}}{g} + \rho_{He} V' + m_{skin}} - g$$

Substitute numerical values and evaluate a:

$$a = \frac{(1.293\,\text{kg/m}^3)(140\,\text{m}^3)(9.81\,\text{m/s}^2)}{\frac{900\text{ N}}{9.81\,\text{m/s}^2} + (0.1786\,\text{kg/m}^3)(140\,\text{m}^3) + 1.5\,\text{kg}} - 9.81\,\text{m/s}^2 = \boxed{5.2\text{ m/s}^2}$$

90 •• A hollow sphere with an inner radius R and an outer radius $2R$. It is made of material of density ρ_0 and is floating in a liquid of density $2\rho_0$. The interior is now completely filled with material of density ρ' such that that the sphere just floats completely submerged. Find ρ'.

Picture the Problem When the hollow sphere is completely submerged but floating, it is in translational equilibrium under the influence of a buoyant force and its weight. The buoyant force is given by Archimedes' principle and the weight of the sphere is the sum of the weights of the hollow sphere and the material filling its center.

Apply $\sum F_y = 0$ to the hollow sphere:

$$B - w = 0 \qquad (1)$$

Express the buoyant force acting on the completely submerged sphere:

$$B = 2\rho_0 V_{sphere} g = 2\rho_0 \left[\tfrac{4}{3}\pi(2R)^3\right] g = \tfrac{64}{3}\rho_0 \pi R^3 g$$

Express the weight of the sphere when the hollow in it is filled with a material of density ρ':

$$\begin{aligned} w &= \rho_0 V_{\text{hollow sphere}} g + \rho' V_{\text{hollow}} g \\ &= \rho_0\left[\tfrac{4}{3}\pi\left\{(2R)^3 - R^3\right\}\right] g + \rho'\left[\tfrac{4}{3}\pi R^3\right] g \\ &= \tfrac{28}{3}\rho_0 \pi R^3 g + \tfrac{4}{3}\rho' \pi R^3 g \end{aligned}$$

Substitute for B and w in equation (1) to obtain:

$$\tfrac{64}{3}\rho_0 \pi R^3 g - \tfrac{28}{3}\rho_0 \pi R^3 g - \tfrac{4}{3}\rho' \pi R^3 g = 0$$

Solving for ρ' yields:

$$\rho' = \boxed{9\rho_0}$$

91 •• According to *the law of atmospheres*, the fractional decrease in atmospheric pressure is proportional to the change in altitude. This law can be expressed as the differential equation $dP/P = -Cdh$, where C is a positive constant. (a) Show that $P(h) = P_0 e^{-Ch}$ where P_0 is the pressure at $h = 0$, is a

solution of the differential equation. (*b*) Given that the pressure 5.5 km above sea level is half that at sea level, find the constant *C*.

Picture the Problem We can differentiate the function $P(h)$ to show that it satisfies the differential equation $dP/P = -C\,dh$ and in Part (*b*) we can use the approximation $e^{-x} \approx 1 - x$ and $\Delta h << h_0$ to establish the given result.

(*a*) Differentiate $P(h) = P_0\,e^{-Ch}$:

$$\frac{dP}{dh} = -CP_0e^{-Ch} = -CP$$

Separating variables yields:

$$\frac{dP}{P} = \boxed{-C\,dh}$$

(*b*) Take the logarithm of both sides of the function $P(h)$:

$$\ln P = \ln\left(P_0e^{-Ch}\right) = \ln P_0 + \ln e^{-Ch} = \ln\left(P_0\right) - Ch$$

Solving for C yields:

$$C = \frac{1}{h}\ln\left(\frac{P_0}{P}\right)$$

Substitute numerical values and evaluate C:

$$C = \frac{1}{5.5\,\text{km}}\ln\left(\frac{P_0}{\frac{1}{2}P_0}\right) = \frac{1}{5.5\,\text{km}}\ln 2 = \boxed{0.13\,\text{km}^{-1}}$$

92 •• A submarine has a total mass of 2.40×10^6 kg, including crew and equipment. The vessel consists of two parts, the pressure hull, which has a volume of $2.00 \times 10^3\ \text{m}^3$, and the ballast tanks, which have a volume of $4.00 \times 10^2\ \text{m}^3$. When the boat cruises on the surface, the ballast tanks are filled with air at atmospheric pressure; to cruise below the surface, seawater must be admitted into the tanks. (*a*) What fraction of the submarine's volume is above the water surface when the tanks are filled with air? (*b*) How much water must be admitted into the tanks to give the submarine neutral buoyancy? Neglect the mass of any air in the tanks and use 1.025 as the specific gravity of seawater.

Picture the Problem Let V represent the volume of the submarine and V' the volume of seawater it displaces when it is on the surface. The submarine is in equilibrium in both parts of the problem. Hence we can apply the condition for translational equilibrium (neutral buoyancy) to the submarine to relate its weight to the buoyant force acting on it. We'll also use Archimedes' principle to connect the buoyant forces to the volume of seawater the submarine displaces. Let upward be the $+y$ direction.

(*a*) Express *f*, the fraction of the submarine's volume above the surface when the tanks are filled with air:

$$f = \frac{V - V'}{V} = 1 - \frac{V'}{V} \qquad (1)$$

Apply $\sum F_y = 0$ to the submarine when its tanks are full of air:

$$B - w = 0$$

Use Archimedes' principle to express the buoyant force on the submarine in terms of the volume of the displaced water:

$$B = \rho_{sw} V' g$$

Substituting for *B* and *w* yields:

$$\rho_{sw} V' g - mg = 0 \Rightarrow V' = \frac{m}{\rho_{sw}}$$

Substitute in equation (1) to obtain:

$$f = 1 - \frac{m}{\rho_{sw} V}$$

Substitute numerical values and evaluate *f*:

$$f = 1 - \frac{2.40 \times 10^6\ \text{kg}}{\left(1.025 \times 10^3\ \text{kg/m}^3\right)\left(2.40 \times 10^3\ \text{m}^3\right)} = \boxed{2.44\%}$$

(*b*) Express the volume of seawater in terms of its mass and density:

$$V_{sw} = \frac{m_{sw}}{\rho_{sw}} \qquad (2)$$

Apply $\sum F_y = 0$, the condition for neutral buoyancy, to the submarine:

$$B - w_{sub} - w_{sw} = 0$$

Use Archimedes' principle to express the buoyant force on the submarine in terms of the volume of the displaced water:

$$B = \rho_{sw} V g$$

Substituting for *B*, w_{sub}, and w_{sw} yields:

$$\rho_{sw} V g - m_{sub} g - m_{sw} g = 0$$

Solve for m_{sw} to obtain:

$$m_{sw} = \rho_{sw} V - m_{sub}$$

Substituting for V_{sw} in equation (2) yields:

$$V_{sw} = \frac{\rho_{sw}V - m_{sub}}{\rho_{sw}} = V - \frac{m_{sub}}{\rho_{sw}}$$

Substitute numerical values and evaluate V_{sw}:

$$V_{sw} = 2.40\times10^3\ \text{m}^3 - \frac{2.40\times10^6\ \text{kg}}{1025\,\text{kg/m}^3} = \boxed{60\,\text{m}^3}$$

93 ••• Most species of fish have expandable sacs, commonly known as "swim bladders," that enable fish to rise in the water by filling the bladders with oxygen collected by their gills and to sink by emptying the bladders into the surrounding water. A freshwater fish has an average density equal to 1.05 kg/L when its swim bladder is empty. How large must the volume of oxygen in the fish's swim bladder be if the fish is to have neutral buoyancy? The fish has a mass of 0.825 kg. Assume the density of oxygen in the bladder is equal to air density at standard temperature and pressure.

Picture the Problem For the fish to achieve neutral buoyancy, its overall density must be lowered to 1.00 kg/L. In order to lower its density, the buoyant force acting on the fish needs to be increased by increasing the fish's volume. It can accomplish this by filling its swim bladder.

Apply the condition for translational equilibrium to the fish:

$$\sum F_y = B - F_g = 0$$

Substitute for B and F_g to obtain:

$$\rho_{water}(V + \delta V)g - mg = 0$$

where V is the fish's volume and δV is the increase in the fish's volume resulting from the additional oxygen in its swim bladder.

Solving for δV yields:

$$\delta V = \frac{m}{\rho_{water}} - V$$

Express the density ρ of the fish:

$$\rho = \frac{m}{V} \Rightarrow V = \frac{m}{\rho}$$

Substitute for V to obtain:

$$\delta V = \frac{m}{\rho_{water}} - \frac{m}{\rho} = m\left(\frac{1}{\rho_{water}} - \frac{1}{\rho}\right)$$

The volume of oxygen transferred to the fish bladders is:

$$\delta V = (0.825\ \text{kg})\left(\frac{1}{1.00\ \frac{\text{kg}}{\text{L}}} - \frac{1}{1.05\ \frac{\text{kg}}{\text{L}}}\right)$$
$$= \boxed{39\ \text{cm}^3}$$

Remarks: In this solution, we've neglected the additional mass of oxygen that should be added to the fish's mass. Consider how small that mass is for a volume of 39 cm^3: $m_{\text{oxygen}} = \rho_{\text{air}}\delta V = (1.293\ \text{kg/m}^3)(39\times10^{-6}\ \text{m}^3) = 50\ \mu\text{g}$.

Chapter 14
Oscillations

Conceptual Problems

1 • True or false:

(*a*) For a simple harmonic oscillator, the period is proportional to the square of the amplitude.
(*b*) For a simple harmonic oscillator, the frequency does not depend on the amplitude.
(*c*) If the net force on a particle undergoing one-dimensional motion is proportional to, and oppositely directed from, the displacement from equilibrium, the motion is simple harmonic.

(*a*) False. In simple harmonic motion, the period is independent of the amplitude.

(*b*) True. In simple harmonic motion, the frequency is the reciprocal of the period which, in turn, is independent of the amplitude.

(*c*) True. This is the condition for simple harmonic motion

2 • If the amplitude of a simple harmonic oscillator is tripled, by what factor is the energy changed?

Determine the Concept The energy of a simple harmonic oscillator varies as the square of the amplitude of its motion. Hence, tripling the amplitude increases the energy by a factor of 9.

3 •• **[SSM]** An object attached to a spring exhibits simple harmonic motion with an amplitude of 4.0 cm. When the object is 2.0 cm from the equilibrium position, what percentage of its total mechanical energy is in the form of potential energy? (*a*) One-quarter. (*b*) One-third. (*c*) One-half. (*d*) Two-thirds. (*e*) Three-quarters.

Picture the Problem The total energy of an object undergoing simple harmonic motion is given by $E_{\text{tot}} = \frac{1}{2}kA^2$, where k is the force constant and A is the amplitude of the motion. The potential energy of the oscillator when it is a distance x from its equilibrium position is $U(x) = \frac{1}{2}kx^2$.

Express the ratio of the potential energy of the object when it is 2.0 cm from the equilibrium position to its total energy:

$$\frac{U(x)}{E_{\text{tot}}} = \frac{\frac{1}{2}kx^2}{\frac{1}{2}kA^2} = \frac{x^2}{A^2}$$

Evaluate this ratio for $x = 2.0$ cm and $A = 4.0$ cm:

$$\frac{U(2\,\text{cm})}{E_{\text{tot}}} = \frac{(2.0\,\text{cm})^2}{(4.0\,\text{cm})^2} = \frac{1}{4}$$

and $\boxed{(a)}$ is correct.

4 • An object attached to a spring exhibits simple harmonic motion with an amplitude of 10.0 cm. How far from equilibrium will the object be when the system's potential energy is equal to its kinetic energy? (*a*) 5.00 cm. (*b*) 7.07 cm. (*c*) 9.00 cm. (*d*) The distance can't be determined from the data given.

Determine the Concept Because the object's total energy is the sum of its kinetic and potential energies, when its potential energy equals its kinetic energy, its potential energy (and its kinetic energy) equals one-half its total energy.

Equate the object's potential energy to one-half its total energy:

$$U_{\text{s}} = \tfrac{1}{2}E_{\text{total}}$$

Substituting for U_{s} and E_{total} yields:

$$\tfrac{1}{2}kx^2 = \tfrac{1}{2}\left(\tfrac{1}{2}kA^2\right) \Rightarrow x = \frac{A}{\sqrt{2}}$$

Substitute the numerical value of A and evaluate x to obtain:

$$\boldsymbol{x} = \frac{10.0\,\text{cm}}{\sqrt{2}} = 7.07\,\text{cm}$$

and $\boxed{(b)}$ is correct.

5 • Two identical systems each consist of a spring with one end attached to a block and the other end attached to a wall. The springs are horizontal, and the blocks are supported from below by a frictionless horizontal table. The blocks are oscillating in simple harmonic motions such that the amplitude of the motion of block A is four times as large as the amplitude of the motion of block B. How do their maximum speeds compare? (*a*) $v_{\text{A max}} = v_{\text{B max}}$, (*b*) $v_{\text{A max}} = 2v_{\text{B max}}$, (*c*) $v_{\text{A max}} = 4v_{\text{B max}}$, (*d*) This comparison cannot be done by using the data given.

Determine the Concept The maximum speed of a simple harmonic oscillator is the product of its angular frequency and its amplitude. The angular frequency of a simple harmonic oscillator is the square root of the quotient of the force constant of the spring and the mass of the oscillator.

Relate the maximum speed of system A to the amplitude of its motion:

$$v_{\text{A max}} = \omega_{\text{A}} A_{\text{A}}$$

Relate the maximum speed of system B to the amplitude of its motion:

$$v_{\text{B max}} = \omega_{\text{B}} A_{\text{B}}$$

Divide the first of these equations by the second to obtain:

$$\frac{v_{\text{A max}}}{v_{\text{B max}}} = \frac{\omega_{\text{A}} A_{\text{A}}}{\omega_{\text{B}} A_{\text{B}}}$$

Because the systems differ only in amplitude, $\omega_{\text{A}} = \omega_{\text{B}}$, and:

$$\frac{v_{\text{A max}}}{v_{\text{B max}}} = \frac{A_{\text{A}}}{A_{\text{B}}}$$

Substituting for A_{A} and simplifying yields:

$$\frac{v_{\text{A max}}}{v_{\text{B max}}} = \frac{4A_{\text{B}}}{A_{\text{B}}} = 4 \Rightarrow v_{\text{A max}} = 4v_{\text{B max}}$$

$\boxed{(c)}$ is correct.

6 • Two systems each consist of a spring with one end attached to a block and the other end attached to a wall. The springs are horizontal, and the blocks are supported from below by a frictionless horizontal table. The blocks are oscillating in simple harmonic motions with equal amplitudes. However, the force constant of spring A is four times as large as the force constant of spring B. How do their maximum speeds compare? (*a*) $v_{\text{A max}} = v_{\text{B max}}$, (*b*) $v_{\text{A max}} = 2v_{\text{B max}}$, (*c*) $v_{\text{A max}} = 4v_{\text{B max}}$, (*d*) This comparison cannot be done by using the data given.

Determine the Concept The maximum speed of a simple harmonic oscillator is the product of its angular frequency and its amplitude. The angular frequency of a simple harmonic oscillator is the square root of the quotient of the force constant of the spring and the mass of the oscillator.

Relate the maximum speed of system A to its force constant:

$$v_{\text{A max}} = \omega_{\text{A}} A_{\text{A}} = \sqrt{\frac{k_{\text{A}}}{m_{\text{A}}}} A_{\text{A}}$$

Relate the maximum speed of system B to its force constant:

$$v_{\text{B max}} = \omega_{\text{B}} A_{\text{B}} = \sqrt{\frac{k_{\text{B}}}{m_{\text{B}}}} A_{\text{B}}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{v_{\text{A max}}}{v_{\text{B max}}} = \frac{\sqrt{\frac{k_{\text{A}}}{m_{\text{A}}}} A_{\text{A}}}{\sqrt{\frac{k_{\text{B}}}{m_{\text{B}}}} A_{\text{B}}} = \sqrt{\frac{m_{\text{B}}}{m_{\text{A}}} \frac{k_{\text{A}}}{k_{\text{B}}}} \frac{A_{\text{A}}}{A_{\text{B}}}$$

Because the systems differ only in their force constants:

$$\frac{v_{\text{A max}}}{v_{\text{B max}}} = \sqrt{\frac{k_{\text{A}}}{k_{\text{B}}}}$$

Substituting for k_A and simplifying yields:

$$\frac{v_{\text{A max}}}{v_{\text{B max}}} = \sqrt{\frac{4k_B}{k_B}} = 2 \Rightarrow v_{\text{A max}} = 2v_{\text{B max}}$$

$\boxed{(b)}$ is correct.

7 •• **[SSM]** Two systems each consist of a spring with one end attached to a block and the other end attached to a wall. The identical springs are horizontal, and the blocks are supported from below by a frictionless horizontal table. The blocks are oscillating in simple harmonic motions with equal amplitudes. However, the mass of block A is four times as large as the mass of block B. How do their maximum speeds compare? (*a*) $v_{\text{A max}} = v_{\text{B max}}$, (*b*) $v_{\text{A max}} = 2v_{\text{B max}}$, (*c*) $v_{\text{A max}} = \frac{1}{2}v_{\text{B max}}$, (*d*) This comparison cannot be done by using the data given.

Determine the Concept The maximum speed of a simple harmonic oscillator is the product of its angular frequency and its amplitude. The angular frequency of a simple harmonic oscillator is the square root of the quotient of the force constant of the spring and the mass of the oscillator.

Relate the maximum speed of system A to its force constant:

$$v_{\text{A max}} = \omega_A A_A = \sqrt{\frac{k_A}{m_A}} A_A$$

Relate the maximum speed of system B to its force constant:

$$v_{\text{B max}} = \omega_B A_B = \sqrt{\frac{k_B}{m_B}} A_B$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{v_{\text{A max}}}{v_{\text{B max}}} = \frac{\sqrt{\frac{k_A}{m_A}} A_A}{\sqrt{\frac{k_B}{m_B}} A_B} = \sqrt{\frac{m_B}{m_A}\frac{k_A}{k_B}}\frac{A_A}{A_B}$$

Because the systems differ only in the masses attached to the springs:

$$\frac{v_{\text{A max}}}{v_{\text{B max}}} = \sqrt{\frac{m_B}{m_A}}$$

Substituting for m_A and simplifying yields:

$$\frac{v_{\text{A max}}}{v_{\text{B max}}} = \sqrt{\frac{m_B}{4m_B}} = \tfrac{1}{2} \Rightarrow v_{\text{A max}} = \tfrac{1}{2}v_{\text{B max}}$$

$\boxed{(c)}$ is correct.

8 •• Two systems each consist of a spring with one end attached to a block and the other end attached to a wall. The identical springs are horizontal, and the blocks are supported from below by a frictionless horizontal table. The blocks are

oscillating in simple harmonic motions with equal amplitudes. However, the mass of block A is four times as large as the mass of block B. How do the magnitudes of their maximum acceleration compare? (*a*) $a_{\text{A max}} = a_{\text{B max}}$, (*b*) $a_{\text{A max}} = 2a_{\text{B max}}$, (*c*) $a_{\text{A max}} = \frac{1}{2}a_{\text{B max}}$, (*d*) $a_{\text{A max}} = \frac{1}{4}a_{\text{B max}}$, (*e*) This comparison cannot be done by using the data given.

Determine the Concept The maximum acceleration of a simple harmonic oscillator is the product of the square of its angular frequency and its amplitude. The angular frequency of a simple harmonic oscillator is the square root of the quotient of the force constant of the spring and the mass of the oscillator.

Relate the maximum acceleration of system A to its force constant:

$$a_{\text{A max}} = \omega_{\text{A}}^2 A_{\text{A}} = \frac{k_{\text{A}}}{m_{\text{A}}} A_{\text{A}}$$

Relate the maximum acceleration of system B to its force constant:

$$a_{\text{B max}} = \omega_{\text{B}}^2 A_{\text{B}} = \frac{k_{\text{B}}}{m_{\text{B}}} A_{\text{B}}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{a_{\text{A max}}}{a_{,\text{max}}} = \frac{\frac{k_{\text{A}}}{m_{\text{A}}} A_{\text{A}}}{\frac{k_{\text{B}}}{m_{\text{B}}} A_{\text{B}}} = \frac{m_{\text{B}}}{m_{\text{A}}} \frac{k_{\text{A}}}{k_{\text{B}}} \frac{A_{\text{A}}}{A_{\text{B}}}$$

Because the systems differ only in the masses attached to the springs:

$$\frac{a_{\text{A max}}}{a_{\text{B max}}} = \frac{m_{\text{B}}}{m_{\text{A}}}$$

Substituting for m_{A} and simplifying yields:

$$\frac{a_{\text{A max}}}{a_{\text{B max}}} = \frac{m_{\text{B}}}{4m_{\text{B}}} = \frac{1}{4} \Rightarrow a_{\text{A max}} = \frac{1}{4} a_{\text{B max}}$$

$\boxed{(d)}$ is correct.

9 •• **[SSM]** In general physics courses, the mass of the spring in simple harmonic motion is usually neglected because its mass is usually much smaller than the mass of the object attached to it. However, this is not always the case. If you neglect the mass of the spring when it is not negligible, how will your calculation of the system's period, frequency and total energy compare to the actual values of these parameters? Explain.

Determine the Concept Neglecting the mass of the spring, the period of a simple harmonic oscillator is given by $T = 2\pi/\omega = 2\pi\sqrt{m/k}$ where m is the mass of the oscillating system (spring plus object) and its total energy is given by $E_{\text{total}} = \frac{1}{2}kA^2$.

Neglecting the mass of the spring results in your using a value for the mass of the oscillating system that is smaller than its actual value. Hence, your calculated value for the period will be smaller than the actual period of the system and the calculated value for the frequency, which is the reciprocal of the period, will be higher than the actual value.

Because the total energy of the oscillating system depends solely on the amplitude of its motion and on the stiffness of the spring, it is independent of the mass of the system, and so neglecting the mass of the spring would have no effect on your calculation of the system's total energy.

10 •• Two mass–spring systems oscillate with periods T_A and T_B. If $T_A = 2T_B$ and the systems' springs have identical force constants, it follows that the systems' masses are related by (*a*) $m_A = 4m_B$, (*b*) $m_A = m_B/\sqrt{2}$, (*c*) $m_A = m_B/2$, (*d*) $m_A = m_B/4$.

Picture the Problem We can use $T = 2\pi\sqrt{m/k}$ to express the periods of the two mass-spring systems in terms of their force constants. Dividing one of the equations by the other will allow us to express m_A in terms of m_B.

Express the period of system A:

$$T_A = 2\pi\sqrt{\frac{m_A}{k_A}} \Rightarrow m_A = \frac{k_A T_A^2}{4\pi^2}$$

Relate the mass of system B to its period:

$$m_B = \frac{k_B T_B^2}{4\pi^2}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{m_A}{m_B} = \frac{\dfrac{k_A T_A^2}{4\pi^2}}{\dfrac{k_B T_B^2}{4\pi^2}} = \frac{k_A T_A^2}{k_B T_B^2}$$

Because the force constants of the two systems are the same:

$$\frac{m_A}{m_B} = \frac{T_A^2}{T_B^2} = \left(\frac{T_A}{T_B}\right)^2$$

Substituting for T_A and simplifying yields:

$$\frac{m_A}{m_B} = \left(\frac{2T_B}{T_B}\right)^2 = 4 \Rightarrow m_A = 4m_B$$

$\boxed{(a)}$ is correct.

11 •• Two mass–spring systems oscillate at frequencies f_A and f_B. If $f_A = 2f_B$ and the systems' springs have identical force constants, it follows that the systems' masses are related by (*a*) $m_A = 4m_B$, (*b*) $m_A = m_B/\sqrt{2}$, (*c*) $m_A = m_B/2$, (*d*) $m_A = m_B/4$.

Picture the Problem We can use $f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$ to express the frequencies of the two mass-spring systems in terms of their masses. Dividing one of the equations by the other will allow us to express m_A in terms of m_B.

Express the frequency of mass-spring system A as a function of its mass:

$$f_A = \frac{1}{2\pi}\sqrt{\frac{k}{m_A}}$$

Express the frequency of mass-spring system B as a function of its mass:

$$f_B = \frac{1}{2\pi}\sqrt{\frac{k}{m_B}}$$

Divide the second of these equations by the first to obtain:

$$\frac{f_B}{f_A} = \sqrt{\frac{m_A}{m_B}}$$

Solve for m_A:

$$m_A = \left(\frac{f_B}{f_A}\right)^2 m_B = \left(\frac{f_B}{2f_B}\right)^2 m_B = \tfrac{1}{4}m_B$$

$\boxed{(d)}$ is correct.

12 •• Two mass–spring systems *A* and *B* oscillate so that their total mechanical energies are equal. If $m_A = 2m_B$, which expression best relates their amplitudes? (*a*) $A_A = A_B/4$, (*b*) $A_A = A_B/\sqrt{2}$, (*c*) $A_A = A_B$, (*d*) Not enough information is given to determine the ratio of the amplitudes.

Picture the Problem We can relate the energies of the two mass-spring systems through either $E = \frac{1}{2}kA^2$ or $E = \frac{1}{2}m\omega^2A^2$ and investigate the relationship between their amplitudes by equating the expressions, substituting for m_A, and expressing A_A in terms of A_B.

Express the energy of mass-spring system A: $E_A = \frac{1}{2}k_A A_A^2 = \frac{1}{2}m_A\omega_A^2 A_A^2$

Express the energy of mass-spring system B: $E_B = \frac{1}{2}k_B A_B^2 = \frac{1}{2}m_B\omega_B^2 A_B^2$

Divide the first of these equations by the second to obtain:

$$\frac{E_A}{E_B} = 1 = \frac{\frac{1}{2}m_A\omega_A^2 A_A^2}{\frac{1}{2}m_B\omega_B^2 A_B^2}$$

Substitute for m_A and simplify:

$$1 = \frac{2m_B\omega_A^2 A_A^2}{m_B\omega_B^2 A_B^2} = \frac{2\omega_A^2 A_A^2}{\omega_B^2 A_B^2}$$

Solve for A_A:

$$A_A = \frac{\omega_B}{\sqrt{2}\omega_A}A_B$$

Without knowing how ω_A and ω_B, or k_A and k_B, are related, we cannot simplify this expression further. $\boxed{(d)}$ is correct.

13 •• [SSM] Two mass–spring systems *A* and *B* oscillate so that their total mechanical energies are equal. If the force constant of spring A is two times the force constant of spring B, then which expression best relates their amplitudes? (*a*) $A_A = A_B/4$, (*b*) $A_A = A_B/\sqrt{2}$, (*c*) $A_A = A_B$, (*d*) Not enough information is given to determine the ratio of the amplitudes.

Picture the Problem We can express the energy of each system using $E = \frac{1}{2}kA^2$ and, because the energies are equal, equate them and solve for A_A.

Express the energy of mass-spring system A in terms of the amplitude of its motion: $E_A = \frac{1}{2}k_A A_A^2$

Express the energy of mass-spring system B in terms of the amplitude of its motion: $E_B = \frac{1}{2}k_B A_B^2$

Because the energies of the two systems are equal we can equate them to obtain:

$$\frac{1}{2}k_A A_A^2 = \frac{1}{2}k_B A_B^2 \Rightarrow A_A = \sqrt{\frac{k_B}{k_A}}A_B$$

Substitute for k_A and simplify to obtain:

$$A_A = \sqrt{\frac{k_B}{2k_B}}A_B = \frac{A_B}{\sqrt{2}} \Rightarrow \boxed{(b)} \text{ is correct.}$$

14 •• The length of the string or wire supporting a pendulum bob increases slightly when the temperature of the string or wire is raised. How does this affect a clock operated by a simple pendulum?

Determine the Concept The period of a simple pendulum depends on the square root of the length of the pendulum. Increasing the length of the pendulum will lengthen its period and, hence, the clock will run slow.

15 •• A lamp hanging from the ceiling of the club car in a train oscillates with period T_0 when the train is at rest. The period will be (match left and right columns)

1. greater than T_0 when	A. The train moves horizontally at constant velocity.
2. less than T_0 when	B. The train rounds a curve at constant speed.
3. equal to T_0 when	C. The train climbs a hill at constant speed.
	D. The train goes over the crest of a hill at constant speed.

Determine the Concept The period of the lamp varies inversely with the square root of the effective value of the local gravitational field.

1 matches up with B. The period will be greater than T_0 when the train rounds a curve of radius R with speed v.

2 matches up with D. The period will be less than T_0 when the train goes over the crest of a hill of radius of curvature R with constant speed.

3 matches up with A. The period will be equal to T_0 when the train moves horizontally with constant velocity.

16 •• Two simple pendulums are related as follows. Pendulum A has a length L_A and a bob of mass m_A; pendulum B has a length L_B and a bob of mass m_B. If the period of A is twice that of B, then (*a*) $L_A = 2L_B$ and $m_A = 2m_B$,

(b) $L_A = 4L_B$ and $m_A = m_B$, (c) $L_A = 4L_B$ whatever the ratio m_A/m_B, (d) $L_A = \sqrt{2}L_B$ whatever the ratio m_A/m_B.

Picture the Problem The period of a simple pendulum is independent of the mass of its bob and is given by $T = 2\pi\sqrt{L/g}$.

Express the period of pendulum A:

$$T_A = 2\pi\sqrt{\frac{L_A}{g}}$$

Express the period of pendulum B:

$$T_B = 2\pi\sqrt{\frac{L_B}{g}}$$

Divide the first of these equations by the second and solve for L_A/L_B:

$$\frac{L_A}{L_B} = \left(\frac{T_A}{T_B}\right)^2$$

Substitute for T_A and solve for L_B to obtain:

$$L_A = \left(\frac{2T_B}{T_B}\right)^2 L_B = 4L_B$$

$\boxed{(c)}$ is correct.

17 •• [SSM] Two simple pendulums are related as follows. Pendulum A has a length L_A and a bob of mass m_A; pendulum B has a length L_B and a bob of mass m_B. If the frequency of A is one-third that of B, then (a) $L_A = 3L_B$ and $m_A = 3m_B$, (b) $L_A = 9L_B$ and $m_A = m_B$, (c) $L_A = 9L_B$ regardless of the ratio m_A/m_B, (d) $L_A = \sqrt{3}L_B$ regardless of the ratio m_A/m_B.

Picture the Problem The frequency of a simple pendulum is independent of the mass of its bob and is given by $f = \frac{1}{2\pi}\sqrt{g/L}$.

Express the frequency of pendulum A:

$$f_A = \frac{1}{2\pi}\sqrt{\frac{g}{L_A}} \Rightarrow L_A = \frac{g}{4\pi^2 f_A^2}$$

Similarly, the length of pendulum B is given by:

$$L_B = \frac{g}{4\pi^2 f_B^2}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{L_A}{L_B}=\frac{\dfrac{g}{4\pi^2 f_A^2}}{\dfrac{g}{4\pi^2 f_B^2}}=\frac{f_B^2}{f_A^2}=\left(\frac{f_B}{f_A}\right)^2$$

Substitute for f_A to obtain:

$$\frac{L_A}{L_B}=\left(\frac{f_B}{\frac{1}{3}f_B}\right)^2=9\Rightarrow\boxed{(c)}\text{ is correct.}$$

18 •• Two simple pendulums are related as follows. Pendulum A has a length L_A and a bob of mass m_A; pendulum B has a length L_B a bob of mass m_B. They have the same period. The only thing different between their motions is that the amplitude of A's motion is twice that of B's motion, then (*a*) $L_A = L_B$ and $m_A = m_B$, (*b*) $L_A = 2L_B$ and $m_A = m_B$, (*c*) $L_A = L_B$ whatever the ratio m_A/m_B, (*d*) $L_A = \frac{1}{2}L_B$ whatever the ratio m_A/m_B.

Picture the Problem The period of a simple pendulum is independent of the mass of its bob and is given by $T = 2\pi\sqrt{L/g}$. For small amplitudes, the period is independent of the amplitude.

Express the period of pendulum A:

$$T_A = 2\pi\sqrt{\frac{L_A}{g}}$$

Express the period of pendulum B:

$$T_B = 2\pi\sqrt{\frac{L_B}{g}}$$

Divide the first of these equations by the second and solve for L_A/L_B:

$$\frac{L_A}{L_B}=\left(\frac{T_A}{T_B}\right)^2$$

Because their periods are the same:

$$\frac{L_A}{L_B}=\left(\frac{T_B}{T_B}\right)^2=1\Rightarrow\boxed{(c)}\text{ is correct.}$$

19 •• True or false:

(*a*) The mechanical energy of a damped, undriven oscillator decreases exponentially with time.
(*b*) Resonance for a damped, driven oscillator occurs when the driving frequency exactly equals the natural frequency.
(*c*) If the Q factor of a damped oscillator is high, then its resonance curve will be narrow.

(*d*) The decay time τ for a spring-mass oscillator with linear damping is independent of its mass.
(*e*) The Q factor for a driven spring-mass oscillator with linear damping is independent of its mass.

(*a*) True. Because the energy of an oscillator is proportional to the square of its amplitude, and the amplitude of a damped, undriven oscillator decreases exponentially with time, so does its energy.

(*b*) False. For a damped driven oscillator, the resonant frequency ω' is given by $\omega' = \omega_0\sqrt{1-\left(\frac{b}{2m\omega_0}\right)^2}$, where ω_0 is the natural frequency of the oscillator.

(*c*) True. The ratio of the width of a resonance curve to the resonant frequency equals the reciprocal of the Q factor ($\Delta\boldsymbol{\omega}/\boldsymbol{\omega}_0 = 1/\boldsymbol{Q}$). Hence, the larger Q is, the narrower the resonance curve.

(*d*) False. The decay time for a damped but undriven spring-mass oscillator is directly proportional to its mass.

(*e*) True. From $\Delta\omega/\omega_0 = 1/Q$ one can see that Q is independent of m.

20 •• Two damped spring-mass oscillating systems have identical spring and damping constants. However, system A's mass m_A is four times system B's. How do their decay times compare? (*a*) $\tau_A = 4\tau_B$, (*b*) $\tau_A = 2\tau_B$, (*c*) $\tau_A = \tau_B$, (*d*) Their decay times cannot be compared, given the information provided.

Picture the Problem The decay time τ of a damped oscillator is related to the mass m of the oscillator and the damping constant b for the motion according to $\tau = m/b$.

Express the decay time of System A:

$$\tau_A = \frac{m_A}{b_A}$$

The decay time for System B is given by:

$$\tau_B = \frac{m_B}{b_B}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{\tau_A}{\tau_B} = \frac{\frac{m_A}{b_A}}{\frac{m_B}{b_B}} = \frac{m_A}{m_B}\frac{b_B}{b_A}$$

Because their damping constants are the same:

$$\frac{\tau_A}{\tau_B} = \frac{m_A}{m_B}$$

Substituting for m_A yields:

$$\frac{\tau_A}{\tau_B} = \frac{4m_B}{m_B} = 4 \Rightarrow \tau_A = 4\tau_B$$

$\boxed{(a)}$ is correct.

21 •• Two damped spring-mass oscillating systems have identical spring constants and decay times. However, system A's mass m_A is twice system B's mass m_B. How do their damping constants, b, compare? (*a*) $b_A = 4b_B$, (*b*) $b_A = 2b_B$, (*c*) $b_A = b_B$, (*d*) $b_A = \frac{1}{2}b_B$, (*e*) Their decay times cannot be compared, given the information provided.

Picture the Problem The decay time τ of a damped oscillator is related to the mass m of the oscillator and the damping constant b for the motion according to $\tau = m/b$.

Express the damping constant of System A:

$$b_A = \frac{m_A}{\tau_A}$$

The damping constant for System B is given by:

$$b_B = \frac{m_B}{\tau_B}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{b_A}{b_B} = \frac{\dfrac{m_A}{\tau_A}}{\dfrac{m_B}{\tau_B}} = \frac{m_A}{m_B}\frac{\tau_B}{\tau_A}$$

Because their decay times are the same:

$$\frac{b_A}{b_B} = \frac{m_A}{m_B}$$

Substituting for m_A yields:

$$\frac{b_A}{b_B} = \frac{2m_B}{m_B} = 2 \Rightarrow b_A = 2b_B$$

$\boxed{(b)}$ is correct.

22 •• Two damped, driven spring-mass oscillating systems have identical driving forces as well as identical spring and damping constants. However, the mass of system A is four times the mass of system B. Assume both systems are very weakly damped. How do their resonant frequencies compare? (*a*) $\omega_A = \omega_B$, (*b*) $\omega_A = 2\omega_B$, (*c*) $\omega_A = \frac{1}{2}\omega_B$, (*d*) $\omega_A = \frac{1}{4}\omega_B$, (*e*) Their resonant frequencies cannot be compared, given the information provided.

Picture the Problem For very weak damping, the resonant frequency of a spring-mass oscillator is the same as its natural frequency and is given by $\omega_0 = \sqrt{k/m}$, where m is the oscillator's mass and k is the force constant of the spring.

Express the resonant frequency of System A:

$$\omega_A = \sqrt{\frac{k_A}{m_A}}$$

The resonant frequency of System B is given by:

$$\omega_B = \sqrt{\frac{k_B}{m_B}}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{\omega_A}{\omega_B} = \frac{\sqrt{\dfrac{k_A}{m_A}}}{\sqrt{\dfrac{k_B}{m_B}}} = \sqrt{\frac{k_A}{k_B}\frac{m_B}{m_A}}$$

Because their force constants are the same:

$$\frac{\omega_A}{\omega_B} = \sqrt{\frac{m_B}{m_A}}$$

Substituting for m_A yields:

$$\frac{\omega_A}{\omega_B} = \sqrt{\frac{m_B}{4m_B}} = \tfrac{1}{2} \Rightarrow \boxed{(c)} \text{ is correct.}$$

23 •• [SSM] Two damped, driven spring-mass oscillating systems have identical masses, driving forces, and damping constants. However, system A's force constant k_A is four times system B's force constant k_B. Assume they are both very weakly damped. How do their resonant frequencies compare? (*a*) $\omega_A = \omega_B$, (*b*) $\omega_A = 2\omega_B$, (*c*) $\omega_A = \frac{1}{2}\omega_B$, (*d*) $\omega_A = \frac{1}{4}\omega_B$, (*e*) Their resonant frequencies cannot be compared, given the information provided.

Picture the Problem For very weak damping, the resonant frequency of a spring-mass oscillator is the same as its natural frequency and is given by $\omega_0 = \sqrt{k/m}$, where m is the oscillator's mass and k is the force constant of the spring.

Express the resonant frequency of System A:

$$\omega_A = \sqrt{\frac{k_A}{m_A}}$$

The resonant frequency of System B is given by:

$$\omega_B = \sqrt{\frac{k_B}{m_B}}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{\omega_A}{\omega_B}=\frac{\sqrt{\frac{k_A}{m_A}}}{\sqrt{\frac{k_B}{m_B}}}=\sqrt{\frac{k_A}{k_B}\frac{m_B}{m_A}}$$

Because their masses are the same:

$$\frac{\omega_A}{\omega_B}=\sqrt{\frac{k_A}{k_B}}$$

Substituting for k_A yields:

$$\frac{\omega_A}{\omega_B}=\sqrt{\frac{4k_B}{k_B}}=2\Rightarrow\boxed{(b)}\text{ is correct.}$$

24 •• Two damped, driven simple-pendulum systems have identical masses, driving forces, and damping constants. However, system A's length is four times system B's length. Assume they are both very weakly damped. How do their resonant frequencies compare? (*a*) $\omega_A=\omega_B$, (*b*) $\omega_A=2\omega_B$, (*c*) $\omega_A=\frac{1}{2}\omega_B$, (*d*) $\omega_A=\frac{1}{4}\omega_B$, (*e*) Their resonant frequencies cannot be compared, given the information provided.

Picture the Problem For very weak damping, the resonant frequency of a simple pendulum is the same as its natural frequency and is given by $\omega_0=\sqrt{g/L}$, where L is the length of the simple pendulum and g is the gravitational field.

Express the resonant frequency of System A:

$$\omega_A=\sqrt{\frac{g}{L_A}}$$

The resonant frequency of System B is given by:

$$\omega_B=\sqrt{\frac{g}{L_B}}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{\omega_A}{\omega_B}=\frac{\sqrt{\frac{g}{L_A}}}{\sqrt{\frac{g}{L_B}}}=\sqrt{\frac{L_B}{L_A}}$$

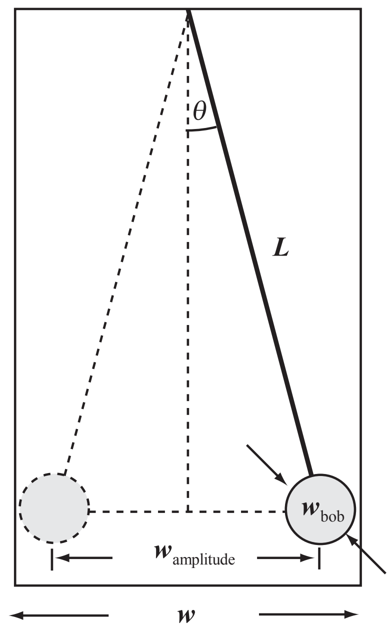
Substituting for L_A yields:

$$\frac{\omega_A}{\omega_B}=\sqrt{\frac{L_B}{4L_B}}=\tfrac{1}{2}\Rightarrow\boxed{(c)}\text{ is correct.}$$

Estimation and Approximation

25 • **[SSM]** Estimate the width of a typical grandfather clocks' cabinet relative to the width of the pendulum bob, presuming the desired motion of the pendulum is simple harmonic.

Picture the Problem If the motion of the pendulum in a grandfather clock is to be simple harmonic motion, then its period must be independent of the angular amplitude of its oscillations. The period of the motion for large-amplitude oscillations is given by Equation 14-30 and we can use this expression to obtain a maximum value for the amplitude of swinging pendulum in the clock. We can then use this value and an assumed value for the length of the pendulum to estimate the width of the grandfather clocks' cabinet.



Referring to the diagram, we see that the minimum width of the cabinet is determined by the width of the bob and the width required to accommodate the swinging pendulum:

$$w = w_{\text{bob}} + w_{\text{amplitude}}$$

and

$$\frac{w}{w_{\text{bob}}} = 1 + \frac{w_{\text{amplitude}}}{w_{\text{bob}}} \qquad (1)$$

Express $w_{\text{amplitude}}$ in terms of the angular amplitude θ and the length of the pendulum L:

$$w_{\text{amplitude}} = 2L\sin\theta$$

Substituting for $w_{\text{amplitude}}$ in equation (1) yields:

$$\frac{w}{w_{\text{bob}}} = 1 + \frac{2L\sin\theta}{w_{\text{bob}}} \qquad (2)$$

Equation 14-30 gives us the period of a simple pendulum as a function of its angular amplitude:

$$T = T_0\left[1 + \frac{1}{2^2}\sin^2\frac{1}{2}\theta + \ldots\right]$$

If T is to be approximately equal to T_0, the second term in the brackets must be small compared to the first term. Suppose that:

$$\frac{1}{4}\sin^2\frac{1}{2}\theta \leq 0.001$$

Solving for θ yields:

$$\theta \leq 2\sin^{-1}(0.0632) \approx 7.25°$$

If we assume that the length of a grandfather clock's pendulum is about 1.5 m and that the width of the bob is about 10 cm, then equation (2) yields:

$$\frac{w}{w_{\text{bob}}} = 1 + \frac{2(1.5\text{ m})\sin 7.25°}{0.10\text{ m}} \approx \boxed{5}$$

26 • A small punching bag for boxing workouts is approximately the size and weight of a person's head and is suspended from a very short rope or chain. Estimate the natural frequency of oscillations of such a punching bag.

Picture the Problem For the purposes of this estimation, model the punching bag as a sphere of radius R and assume that the spindle about which it rotates to be 1.5 times the radius of the sphere. The natural frequency of oscillations of this physical pendulum is given by $f_0 = \omega_0 = \frac{1}{2\pi}\sqrt{\frac{MgD}{I}}$ where M is the mass of the pendulum, D is the distance from the point of support to the center of mass of the punching bag, and I is its moment of inertia about an axis through the spindle from which it is supported and about which it swivels.

Express the natural frequency of oscillation of the punching bag:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{MgD}{I_{\text{spindle}}}} \qquad (1)$$

From the parallel-axis theorem we have:

$$I_{\text{spindle}} = I_{\text{cm}} + Mh^2$$
where $h = 1.5R + 0.5R = 2R$

Substituting for I_{cm} and h yields:

$$I_{\text{spindle}} = \tfrac{2}{5}MR^2 + M(2R)^2 = 4.4MR^2$$

Substitute for I_{spindle} in equation (1) to obtain:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{Mg(2R)}{4.4MR^2}} = \frac{1}{2\pi}\sqrt{\frac{g}{2.2R}}$$

Assume that the radius of the punching bag is 10 cm, substitute numerical values and evaluate f_0:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{9.81\text{ m/s}^2}{2.2(0.10\text{ m})}} \approx \boxed{1\text{ Hz}}$$

27 •• For a child on a swing, the amplitude drops by a factor of $1/e$ in about eight periods if no additional mechanical energy is given to the system. Estimate the Q factor for this system.

Picture the Problem The Q factor for this system is related to the decay constant τ through $Q = \omega_0\tau = 2\pi\tau/T$ and the amplitude of the child's damped motion varies with time according to $A = A_0 e^{-t/2\tau}$. We can set the ratio of two displacements separated by eight periods equal to $1/e$ to determine τ in terms of T.

Express Q as a function of τ:

$$Q = \omega_0\tau = \frac{2\pi\tau}{T} \qquad (1)$$

The amplitude of the oscillations varies with time according to:

$$A = A_0 e^{-t/2\tau}$$

The amplitude after eight periods is:

$$A_8 = A_0 e^{-(t+8T)/2\tau}$$

Express and simplify the ratio A_8/A:

$$\frac{A_8}{A} = \frac{A_0 e^{-(t+8T)/2\tau}}{A_0 e^{-t/2\tau}} = e^{-4T/\tau}$$

Set this ratio equal to $1/e$ and solve for τ:

$$e^{-4T/\tau} = e^{-1} \Rightarrow \tau = 4T$$

Substitute in equation (1) and evaluate Q:

$$Q = \frac{2\pi(4T)}{T} = \boxed{8\pi}$$

28 •• (a) Estimate the natural period of oscillation for swinging your arms as you walk, when your hands are empty. (b) Now estimate the natural period of oscillation when you are carrying a heavy briefcase. (c) Observe other people as they walk. Do your estimates seem reasonable?

Picture the Problem Assume that an average length for an arm is about 80 cm, and that it can be treated as a uniform rod, pivoted at one end. We can use the expression for the period of a physical pendulum to derive an expression for the period of the swinging arm. When carrying a heavy briefcase, the mass is concentrated mostly at the end of the rod (that is, in the briefcase), so we can treat the arm-plus-briefcase system as a simple pendulum.

(*a*) Express the period of a uniform rod pivoted at one end:

$$T = 2\pi\sqrt{\frac{I}{MgD}}$$

where I is the moment of inertia of the stick about an axis through one end, M is the mass of the stick, and D (= $L/2$) is the distance from the end of the stick to its center of mass.

Express the moment of inertia of a rod about an axis through its end:

$$I = \tfrac{1}{3}ML^2$$

Substitute the values for I and D in the expression for T and simplify to obtain:

$$T = 2\pi\sqrt{\frac{\frac{1}{3}ML^2}{Mg\left(\frac{1}{2}L\right)}} = 2\pi\sqrt{\frac{2L}{3g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{2(0.80\,\text{m})}{3(9.81\,\text{m/s}^2)}} = \boxed{1.5\,\text{s}}$$

(*b*) Express the period of a simple pendulum:

$$T' = 2\pi\sqrt{\frac{L'}{g}}$$

where L' is slightly longer than the arm length due to the size of the briefcase.

Assuming $L' = 1.0$ m, evaluate the period of the simple pendulum:

$$T' = 2\pi\sqrt{\frac{1.0\,\text{m}}{9.81\,\text{m/s}^2}} = \boxed{2.0\,\text{s}}$$

(*c*) From observation of people as they walk, these estimates seem reasonable.

Simple Harmonic Motion

29 • The position of a particle is given by $x = (7.0\text{ cm})\cos 6\pi t$, where t is in seconds. What are (*a*) the frequency, (*b*) the period, and (*c*) the amplitude of the particle's motion? (*d*) What is the first time after $t = 0$ that the particle is at its equilibrium position? In what direction is it moving at that time?

Picture the Problem The position of the particle is given by $x = A\cos(\omega t + \delta)$ where A is the amplitude of the motion, ω is the angular frequency, and δ is a phase constant. The frequency of the motion is given by $f = \omega/2\pi$ and the period of the motion is the reciprocal of its frequency.

(*a*) Use the definition of ω to determine f:

$$f = \frac{\omega}{2\pi} = \frac{6\pi\,\text{s}^{-1}}{2\pi} = \boxed{3.00\,\text{Hz}}$$

(*b*) Evaluate the reciprocal of the frequency:

$$T = \frac{1}{f} = \frac{1}{3.00\,\text{Hz}} = \boxed{0.333\,\text{s}}$$

(*c*) Compare $x = (7.0\text{ cm})\cos 6\pi t$ to $x = A\cos(\omega t + \delta)$ to conclude that:

$$A = \boxed{7.0\,\text{cm}}$$

(*d*) Express the condition that must be satisfied when the particle is at its equilibrium position:

$$\cos\omega t = 0 \Rightarrow \omega t = \frac{\pi}{2} \Rightarrow t = \frac{\pi}{2\omega}$$

Substituting for ω yields:

$$t = \frac{\pi}{2(6\pi)} = \boxed{0.0833\,\text{s}}$$

Differentiate x to find $v(t)$:

$$v = \frac{d}{dt}\left[(7.0\,\text{cm})\cos 6\pi t\right] = -(42\pi\text{ cm/s})\sin 6\pi t$$

Evaluate $v(0.0833\text{ s})$:

$$v(0.0833\,\text{s}) = -(42\pi\text{ cm/s})\sin 6\pi(0.0833\,\text{s}) < 0$$

Because $v < 0$, the particle is moving in the $-x$ direction at $t = 0.0833$ s.

30 • What is the phase constant δ in $x = A\cos(\omega t + \delta)$ (Equation 14-4) if the position of the oscillating particle at time $t = 0$ is (*a*) 0, (*b*) $-A$, (*c*) A, (*d*) $A/2$?

Picture the Problem The initial position of the oscillating particle is related to the amplitude and phase constant of the motion by $x_0 = A\cos\delta$ where $0 \le \delta < 2\pi$.

(*a*) For $x_0 = 0$:

$$\cos\delta = 0 \Rightarrow \delta = \cos^{-1}(0) = \boxed{\frac{\pi}{2}, \frac{3\pi}{2}}$$

(*b*) For $x_0 = -A$:

$$-A = A\cos\delta \Rightarrow \delta = \cos^{-1}(-1) = \boxed{\pi}$$

(*c*) For $x_0 = A$:

$$A = A\cos\delta \Rightarrow \delta = \cos^{-1}(1) = \boxed{0}$$

(*d*) When $x = A/2$:

$$\frac{A}{2} = A\cos\delta \Rightarrow \delta = \cos^{-1}\left(\frac{1}{2}\right) = \boxed{\frac{\pi}{3}}$$

31 • **[SSM]** A particle of mass m begins at rest from x = +25 cm and oscillates about its equilibrium position at x = 0 with a period of 1.5 s. Write expressions for (a) the position x as a function of t, (b) the velocity v_x as a function of t, and (c) the acceleration a_x as a function of t.

Picture the Problem The position of the particle as a function of time is given by $x = A\cos(\omega t + \delta)$. The velocity and acceleration of the particle can be found by differentiating the expression for the position of the particle with respect to time.

(a) The position of the particle is given by:

$$x = A\cos(\omega t + \delta)$$

For a particle that begins from rest from x = +25 cm, δ = 0 and A = +25 cm. Hence:

$$x = (+25\ \text{cm})\cos\omega t$$

The angular frequency of the particle's motion is:

$$\omega = \frac{2\pi}{T} = \frac{4\pi}{3}\,\text{s}^{-1} = 4.19\,\text{s}^{-1}$$

Substituting for ω gives:

$$x = (25\,\text{cm})\cos\left[\left(\frac{4\pi}{3}\text{s}^{-1}\right)t\right] = \boxed{(0.25\,\text{m})\cos\left[\left(4.2\,\text{s}^{-1}\right)t\right]}$$

(b) Differentiate the result in Part (a) with respect to time to express the velocity of the particle:

$$v_x = \frac{dx}{dt} = -(25\,\text{cm})\left(\frac{4\pi}{3}\text{s}^{-1}\right)\sin\left[\left(\frac{4\pi}{3}\text{s}^{-1}\right)t\right] = \boxed{-(1.0\,\text{m/s})\sin\left[\left(4.2\,\text{s}^{-1}\right)t\right]}$$

(c) Differentiate the result in Part (b) with respect to time to express the acceleration of the particle:

$$a_x = \frac{dv_x}{dt} = -(25\,\text{cm})\left(\frac{4\pi}{3}\text{s}^{-1}\right)^2\cos\left[\left(\frac{4\pi}{3}\text{s}^{-1}\right)t\right] = \boxed{-\left(4.4\,\text{m/s}^2\right)\cos\left[\left(4.2\,\text{s}^{-1}\right)t\right]}$$

32 •• Find (a) the maximum speed and (b) the maximum acceleration of the particle in Problem 31. (c) What is the first time that the particle is at x = 0 and moving to the right?

Picture the Problem The maximum speed and maximum acceleration of the particle in Problem 29 are given by $v_{max} = A\omega$ and $a_{max} = A\omega^2$. The particle's position is given by $x = A\cos(\omega t + \delta)$ where A = 7.0 cm, $\omega = 6\pi\ \text{s}^{-1}$, and $\delta = 0$, and its velocity is given by $v = -A\omega\sin(\omega t + \delta)$.

(*a*) Express v_{max} in terms of A and ω:

$$v_{max} = A\omega = (7.0\,\text{cm})(6\pi\,\text{s}^{-1}) = 42\pi\,\text{cm/s} = \boxed{1.3\,\text{m/s}}$$

(*b*) Express a_{max} in terms of A and ω:

$$a_{max} = A\omega^2 = (7.0\,\text{cm})(6\pi\,\text{s}^{-1})^2 = 252\pi^2\,\text{cm/s}^2 = \boxed{25\,\text{m/s}^2}$$

(*c*) When $x = 0$:

$$\cos\omega t = 0 \Rightarrow \omega t = \cos^{-1}(0) = \frac{\pi}{2}, \frac{3\pi}{2}$$

Evaluate v for $\omega t = \frac{\pi}{2}$:

$$v = -A\omega\sin\left(\frac{\pi}{2}\right) = -A\omega$$

That is, the particle is moving to the left.

Evaluate v for $\omega t = \frac{3\pi}{2}$:

$$v = -A\omega\sin\left(\frac{3\pi}{2}\right) = A\omega$$

That is, the particle is moving to the right.

Solve $\omega t = \frac{3\pi}{2}$ for t to obtain:

$$t = \frac{3\pi}{2\omega} = \frac{3\pi}{2(6\pi\,\text{s}^{-1})} = \boxed{0.25\,\text{s}}$$

33 •• Work Problem 31 for when the particle initially at x = 25 cm and moving with velocity v_0 = +50 cm/s.

Picture the Problem The position of the particle as a function of time is given by $x = A\cos(\omega t + \delta)$. Its velocity as a function of time is given by $v = -A\omega\sin(\omega t + \delta)$ and its acceleration by $a = -A\omega^2\cos(\omega t + \delta)$. The initial position and velocity give us two equations from which to determine the amplitude A and phase constant δ.

(*a*) Express the position, velocity, and acceleration of the particle as functions of t:

$$x = A\cos(\omega t + \delta) \quad (1)$$

$$v_x = -A\omega\sin(\omega t + \delta) \quad (2)$$

$$a_x = -A\omega^2\cos(\omega t + \delta) \quad (3)$$

Find the angular frequency of the particle's motion:

$$\omega = \frac{2\pi}{T} = \frac{4\pi}{3}\,\mathrm{s}^{-1} = 4.19\,\mathrm{s}^{-1}$$

Relate the initial position and velocity to the amplitude and phase constant:

$$x_0 = A\cos\delta$$
and
$$v_0 = -\omega A\sin\delta$$

Divide these equations to eliminate A:

$$\frac{v_0}{x_0} = \frac{-\omega A\sin\delta}{A\cos\delta} = -\omega\tan\delta$$

Solving for δ yields:

$$\delta = \tan^{-1}\left(-\frac{v_0}{x_0\omega}\right)$$

Substitute numerical values and evaluate δ:

$$\delta = \tan^{-1}\left(-\frac{50\,\mathrm{cm/s}}{(25\,\mathrm{cm})(4.192\,\mathrm{s}^{-1})}\right) = -0.445\,\mathrm{rad}$$

Use either the x_0 or v_0 equation (x_0 is used here) to find the amplitude:

$$A = \frac{x_0}{\cos\delta} = \frac{25\,\mathrm{cm}}{\cos(-0.445\,\mathrm{rad})} = 27.7\,\mathrm{cm}$$

Substitute in equation (1) to obtain:

$$x = \boxed{(0.28\,\mathrm{m})\cos\left[\left(4.2\,\mathrm{s}^{-1}\right)t - 0.45\right]}$$

(*b*) Substitute numerical values in equation (2) to obtain:

$$v_x = -(27.7\,\mathrm{cm})\left(\frac{4\pi}{3}\mathrm{s}^{-1}\right)\sin\left[\left(\frac{4\pi}{3}\mathrm{s}^{-1}\right)t - 0.445\right] = \boxed{-(1.2\,\mathrm{m/s})\sin\left[\left(4.2\,\mathrm{s}^{-1}\right)t - 0.45\right]}$$

(*c*) Substitute numerical values in equation (3) to obtain:

$$a_x = -(27.7\,\mathrm{cm})\left(\frac{4\pi}{3}\mathrm{s}^{-1}\right)^2\cos\left[\left(\frac{4\pi}{3}\mathrm{s}^{-1}\right)t - 0.445\right]$$
$$= \boxed{-\left(4.9\,\mathrm{m/s}^2\right)\cos\left[\left(4.2\,\mathrm{s}^{-1}\right)t - 0.45\right]}$$

34 •• The period of a particle that is oscillating in simple harmonic motion is 8.0 s and its amplitude is 12 cm. At $t = 0$ it is at its equilibrium position. Find the distance it travels during the intervals (*a*) $t = 0$ to $t = 2.0$ s, (*b*) $t = 2.0$ s to $t = 4.0$ s, (*c*) $t = 0$ to $t = 1.0$ s, and (*d*) $t = 1.0$ s to $t = 2.0$ s.

Picture the Problem The position of the particle as a function of time is given by $x = A\cos(\omega t + \delta)$. We're given the amplitude A of the motion and can use the initial position of the particle to determine the phase constant δ. Once we've determined these quantities, we can express the distance traveled Δx during any interval of time.

Express the position of the particle as a function of t:

$$x = (12\,\text{cm})\cos(\omega t + \delta) \quad (1)$$

Find the angular frequency of the particle's motion:

$$\omega = \frac{2\pi}{T} = \frac{2\pi}{8.0\,\text{s}} = \frac{\pi}{4}\,\text{s}^{-1}$$

Relate the initial position of the particle to the amplitude and phase constant:

$$x_0 = A\cos\delta$$

Solve for δ:

$$\delta = \cos^{-1}\left(\frac{x_0}{A}\right) = \cos^{-1}\left(\frac{0}{A}\right) = \frac{\pi}{2}$$

Substitute in equation (1) to obtain:

$$x = (12\,\text{cm})\cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)t + \frac{\pi}{2}\right]$$

Express the distance the particle travels in terms of t_f and t_i:

$$\begin{aligned}\Delta x &= \left|(12\,\text{cm})\cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)t_\text{f} + \frac{\pi}{2}\right] - (12\,\text{cm})\cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)t_\text{i} + \frac{\pi}{2}\right]\right| \\ &= \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)t_\text{f} + \frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)t_\text{i} + \frac{\pi}{2}\right]\right\}\right|\end{aligned}$$

(*a*) Evaluate Δx for $t_\text{f} = 2.0$ s, $t_\text{i} = 0$ s:

$$\Delta x = \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)(2.0\,\text{s}) + \frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)(0) + \frac{\pi}{2}\right]\right\}\right| = \boxed{12\,\text{cm}}$$

(*b*) Evaluate Δx for $t_\text{f} = 4.0$ s, $t_\text{i} = 2.0$ s:

$$\Delta x = \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)(4.0\,\text{s}) + \frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)(2.0\,\text{s}) + \frac{\pi}{2}\right]\right\}\right| = \boxed{12\,\text{cm}}$$

(*c*) Evaluate Δx for $t_f = 1.0$ s, $t_i = 0$:

$$\Delta x = \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(1.0\,\text{s}) + \frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(0) + \frac{\pi}{2}\right]\right\}\right|$$

$$= \left|(12\,\text{cm})\{-0.7071 - 0\}\right| = \boxed{8.5\,\text{cm}}$$

(*d*) Evaluate Δx for $t_f = 2.0$ s, $t_i = 1.0$ s:

$$\Delta x = \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(2.0\,\text{s}) + \frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(1.0\,\text{s}) + \frac{\pi}{2}\right]\right\}\right| = \boxed{3.5\,\text{cm}}$$

35 •• The period of a particle oscillating in simple harmonic motion is 8.0 s. At $t = 0$, the particle is at rest at $x = A = 10$ cm. (*a*) Sketch x as a function of t. (*b*) Find the distance traveled in the first, second, third, and fourth second after $t = 0$.

Picture the Problem The position of the particle as a function of time is given by $x = (10\,\text{cm})\cos(\omega t + \delta)$. We can determine the angular frequency ω from the period of the motion and the phase constant δ from the initial position and velocity. Once we've determined these quantities, we can express the distance traveled Δx during any interval of time.

Express the position of the particle as a function of t:

$$x = (10\,\text{cm})\cos(\omega t + \delta) \qquad (1)$$

Find the angular frequency of the particle's motion:

$$\omega = \frac{2\pi}{T} = \frac{2\pi}{8.0\,\text{s}} = \frac{\pi}{4}\text{s}^{-1}$$

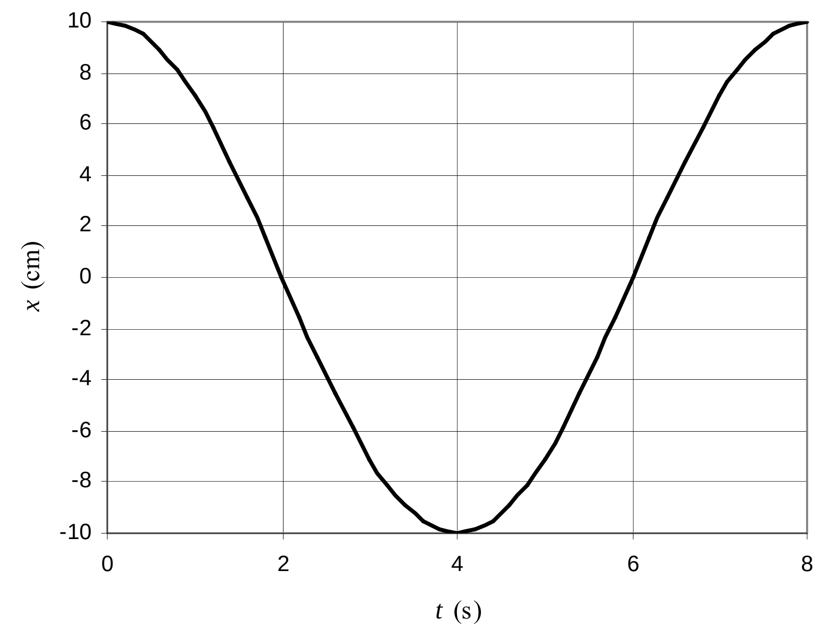
Find the phase constant of the motion:

$$\delta = \tan^{-1}\left(-\frac{v_0}{x_0\omega}\right) = \tan^{-1}\left(-\frac{0}{x_0\omega}\right) = 0$$

Substitute in equation (1) to obtain:

$$x = (10\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t\right]$$

(a) A graph of $x=(10\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t\right]$ follows:



(b) Express the distance the particle travels in terms of t_f and t_i:

$$\begin{aligned}\Delta x &= \left|(10\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_\text{f}\right]-(10\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_\text{i}\right]\right| \\ &= \left|(10\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_\text{f}\right]-\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_\text{i}\right]\right\}\right|\end{aligned} \qquad (2)$$

Substitute numerical values in equation (2) and evaluate Δx in each of the given time intervals to obtain:

t_f (s)	t_i (s)	Δx (cm)
1	0	$\boxed{2.9}$
2	1	$\boxed{7.1}$
3	2	$\boxed{7.1}$
4	3	$\boxed{2.9}$

36 •• Military specifications often call for electronic devices to be able to withstand accelerations of up to $10g$ ($10g = 98.1\ \text{m/s}^2$). To make sure that your company's products meet this specification, your manager has told you to use a "shaking table," which can vibrate a device at controlled and adjustable frequencies and amplitudes. If a device is placed on the table and made to

oscillate at an amplitude of 1.5 cm, what should you adjust the frequency to in order to test for compliance with the 10*g* military specification?

Picture the Problem We can use the expression for the maximum acceleration of an oscillator to relate the 10*g* military specification to the compliance frequency.

Express the maximum acceleration of an oscillator:

$$a_{\max} = A\omega^2$$

Express the relationship between the angular frequency and the frequency of the vibrations:

$$\omega = 2\pi f$$

Substitute for ω to obtain:

$$a_{\max} = 4\pi^2 A f^2 \Rightarrow f = \frac{1}{2\pi}\sqrt{\frac{a_{\max}}{A}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi}\sqrt{\frac{98.1\,\text{m/s}^2}{1.5\times10^{-2}\,\text{m}}} = \boxed{13\,\text{Hz}}$$

37 •• [SSM] The position of a particle is given by $x = 2.5 \cos \pi t$, where x is in meters and t is in seconds. (*a*) Find the maximum speed and maximum acceleration of the particle. (*b*) Find the speed and acceleration of the particle when $x = 1.5$ m.

Picture the Problem The position of the particle is given by $x = A\cos\omega t$, where $A = 2.5$ m and $\omega = \pi$ rad/s. The velocity is the time derivative of the position and the acceleration is the time derivative of the velocity.

(*a*) The velocity is the time derivative of the position and the acceleration is the time derivative of the acceleration:

$$x = A\cos\omega t \Rightarrow v = \frac{dx}{dt} = -\omega A\sin\omega t$$

and $a = \dfrac{dv}{dt} = -\omega^2 A\cos\omega t$

The maximum value of $\sin\omega t$ is +1 and the minimum value of $\sin\omega t$ is −1. A and ω are positive constants:

$$v_{\max} = A\omega = (2.5\,\text{m})(\pi\,\text{s}^{-1}) = \boxed{7.9\,\text{m/s}}$$

The maximum value of $\cos\omega t$ is +1 and the minimum value of $\cos\omega t$ is −1:

$$a_{\max} = A\omega^2 = (2.5\,\text{m})(\pi\,\text{s}^{-1})^2 = \boxed{25\,\text{m/s}^2}$$

(*b*) Use the Pythagorean identity $\sin^2 \omega t + \cos^2 \omega t = 1$ to eliminate *t* from the equations for *x* and *v*:

$$\frac{v^2}{\omega^2 A^2} + \frac{x^2}{A^2} = 1 \Rightarrow |v| = \omega\sqrt{A^2 - x^2}$$

Substitute numerical values and evaluate $|v(1.5\text{ m})|$:

$$|v(1.5\text{ m})| = (\pi\text{ rad/s})\sqrt{(2.5\text{ m})^2 - (1.5\text{ m})^2} = \boxed{6.3\text{ m/s}}$$

Substitute *x* for $A\cos\omega t$ in the equation for *a* to obtain:

$$a = -\omega^2 x$$

Substitute numerical values and evaluate *a*:

$$a = -(\pi\text{ rad/s})^2(1.5\text{ m}) = \boxed{-15\text{ m/s}^2}$$

38 ••• (*a*) Show that $A_0 \cos(\omega t + \delta)$ can be written as $A_s \sin(\omega t) + A_c \cos(\omega t)$, and determine A_s and A_c in terms of A_0 and δ. (*b*) Relate A_c and A_s to the initial position and velocity of a particle undergoing simple harmonic motion.

Picture the Problem We can use the formula for the cosine of the sum of two angles to write $x = A_0 \cos(\omega t + \delta)$ in the desired form. We can then evaluate *x* and dx/dt at $t = 0$ to relate A_c and A_s to the initial position and velocity of a particle undergoing simple harmonic motion.

(*a*) Apply the trigonometric identity $\cos(\omega t + \delta) = \cos\omega t\cos\delta - \sin\omega t\sin\delta$ to obtain:

$$\begin{aligned} x &= A_0\cos(\omega t + \delta) \\ &= A_0[\cos\omega t\cos\delta - \sin\omega t\sin\delta] \\ &= -A_0\sin\delta\sin\omega t + A_0\cos\delta\cos\omega t \\ &= \boxed{A_s\sin\omega t + A_c\cos\omega t} \end{aligned}$$

provided
$A_s = -A_0\sin\delta$ and $A_c = A_0\cos\delta$

(*b*) When $t = 0$:

$$x(0) = \boxed{A_0\cos\delta = A_c}$$

Evaluate dx/dt:

$$\begin{aligned} v &= \frac{dx}{dt} = \frac{d}{dt}[A_s\sin\omega t + A_c\cos\omega t] \\ &= A_s\omega\cos\omega t - A_c\omega\sin\omega t \end{aligned}$$

Evaluate $v(0)$ to obtain:

$$v(0) = \omega A_s = \boxed{-\omega A_0\sin\delta}$$

Simple Harmonic Motion as Related to Circular Motion

39 • **[SSM]** A particle moves at a constant speed of 80 cm/s in a circle of radius 40 cm centered at the origin. (*a*) Find the frequency and period of the *x* component of its position. (*b*) Write an expression for the *x* component of its position as a function of time *t*, assuming that the particle is located on the +*y*-axis at time $t = 0$.

Picture the Problem We can find the period of the motion from the time required for the particle to travel completely around the circle. The frequency of the motion is the reciprocal of its period and the *x*-component of the particle's position is given by $x = A\cos(\omega t + \delta)$. We can use the initial position of the particle to determine the phase constant δ.

(*a*) Use the definition of speed to find the period of the motion:

$$T = \frac{2\pi r}{v} = \frac{2\pi(0.40\,\text{m})}{0.80\,\text{m/s}} = 3.14 = \boxed{3.1\,\text{s}}$$

Because the frequency and the period are reciprocals of each other:

$$f = \frac{1}{T} = \frac{1}{3.14\,\text{s}} = \boxed{0.32\,\text{Hz}}$$

(*b*) Express the *x* component of the position of the particle:

$$x = A\cos(\omega t + \delta) = A\cos(2\pi f t + \delta) \quad (1)$$

The initial condition on the particle's position is:

$$\boldsymbol{x}(0) = 0$$

Substitute in the expression for *x* to obtain:

$$0 = A\cos\delta \Rightarrow \delta = \cos^{-1}(0) = \frac{\pi}{2}$$

Substitute for *A*, ω, and δ in equation (1) to obtain:

$$x = \boxed{(40\,\text{cm})\cos\left[\left(2.0\,\text{s}^{-1}\right)t + \frac{\pi}{2}\right]}$$

40 • A particle moves in a 15-cm-radius circle centered at the origin and completes 1.0 rev every 3.0 s. (*a*) Find the speed of the particle. (*b*) Find its angular speed ω. (*c*) Write an equation for the *x* component of the position of the particle as a function of time *t*, assuming that the particle is on the –*x* axis at time $t = 0$.

Picture the Problem We can find the period of the motion from the time required for the particle to travel completely around the circle. The angular frequency of the motion is 2π times the reciprocal of its period and the *x*-component of the particle's position is given by $x = A\cos(\omega t + \delta)$. We can use the initial position of the particle to determine the phase constant δ.

(*a*) Use the definition of speed to express and evaluate the speed of the particle:

$$v = \frac{2\pi r}{T} = \frac{2\pi(15\,\text{cm})}{3.0\,\text{s}} = \boxed{31\,\text{cm/s}}$$

(*b*) The angular speed of the particle is:

$$\omega = \frac{2\pi}{T} = \frac{2\pi}{3.0\,\text{s}} = \boxed{\frac{2\pi}{3}\,\text{rad/s}}$$

(*c*) Express the *x* component of the position of the particle:

$$x = A\cos(\omega t + \delta) \qquad (1)$$

The initial condition on the particle's position is:

$$x(0) = -A$$

Substituting for *x* in equation (1) yields:

$$-A = A\cos\delta \Rightarrow \delta = \cos^{-1}(-1) = \pi$$

Substitute for *A*, ω, and δ in equation (1) to obtain:

$$x = \boxed{(15\,\text{cm})\cos\left(\left(\frac{2\pi}{3}\,\text{s}^{-1}\right)t + \pi\right)}$$

Energy in Simple Harmonic Motion

41 • A 2.4-kg object on a frictionless horizontal surface is attached to one end of a horizontal spring of force constant k = 4.5 kN/m. The other end of the spring is held stationary. The spring is stretched 10 cm from equilibrium and released. Find the system's total mechanical energy.

Picture the Problem The total mechanical energy of the object is given by $E_{\text{tot}} = \frac{1}{2}kA^2$, where *A* is the amplitude of the object's motion.

The total mechanical energy of the system is given by:

$$E_{\text{tot}} = \tfrac{1}{2}kA^2$$

Substitute numerical values and evaluate E_{tot}:

$$E_{\text{tot}} = \tfrac{1}{2}(4.5\,\text{kN/m})(0.10\,\text{m})^2 = \boxed{23\,\text{J}}$$

42 • Find the total energy of a system consisting of a 3.0-kg object on a frictionless horizontal surface oscillating with an amplitude of 10 cm and a frequency of 2.4 Hz at the end of a horizontal spring.

Picture the Problem The total energy of an oscillating object can be expressed in terms of its kinetic energy as it passes through its equilibrium position: $E_{tot} = \frac{1}{2}mv_{max}^2$. Its maximum speed, in turn, can be expressed in terms of its angular frequency and the amplitude of its motion.

Express the total energy of the object in terms of its maximum kinetic energy:

$$E = \tfrac{1}{2}mv_{max}^2$$

The maximum speed v_{max} of the oscillating object is given by:

$$v_{max} = A\omega = 2\pi Af$$

Substitute for v_{max} to obtain:

$$E = \tfrac{1}{2}m(2\pi Af)^2 = 2mA^2\pi^2 f^2$$

Substitute numerical values and evaluate E:

$$E = 2(3.0\,\text{kg})(0.10\,\text{m})^2\pi^2\left(2.4\,\text{s}^{-1}\right)^2 = \boxed{3.4\,\text{J}}$$

43 • **[SSM]** A 1.50-kg object on a frictionless horizontal surface oscillates at the end of a spring of force constant k = 500 N/m. The object's maximum speed is 70.0 cm/s. (*a*) What is the system's total mechanical energy? (*b*) What is the amplitude of the motion?

Picture the Problem The total mechanical energy of the oscillating object can be expressed in terms of its kinetic energy as it passes through its equilibrium position: $E_{tot} = \frac{1}{2}mv_{max}^2$. Its total energy is also given by $E_{tot} = \frac{1}{2}kA^2$. We can equate these expressions to obtain an expression for A.

(*a*) Express the total mechanical energy of the object in terms of its maximum kinetic energy:

$$E = \tfrac{1}{2}mv_{max}^2$$

Substitute numerical values and evaluate E:

$$E = \tfrac{1}{2}(1.50\,\text{kg})(0.700\,\text{m/s})^2 = 0.3675\,\text{J} = \boxed{0.368\,\text{J}}$$

(*b*) Express the total mechanical energy of the object in terms of the amplitude of its motion:

$$E_{\text{tot}} = \tfrac{1}{2}kA^2 \Rightarrow A = \sqrt{\frac{2E_{\text{tot}}}{k}}$$

Substitute numerical values and evaluate *A*:

$$A = \sqrt{\frac{2(0.3675\,\text{J})}{500\,\text{N/m}}} = \boxed{3.83\,\text{cm}}$$

44 • A 3.0-kg object on a frictionless horizontal surface is oscillating on the end of a spring that has a force constant equal to 2.0 kN/m and a total mechanical energy of 0.90 J. (*a*) What is the amplitude of the motion? (*b*) What is the maximum speed?

Picture the Problem The total mechanical energy of the oscillating object can be expressed in terms of its kinetic energy as it passes through its equilibrium position: $E_{\text{tot}} = \tfrac{1}{2}mv_{\text{max}}^2$. Its total energy is also given by $E_{\text{tot}} = \tfrac{1}{2}kA^2$. We can solve the latter equation to find *A* and solve the former equation for v_{max}.

(*a*) Express the total mechanical energy of the object as a function of the amplitude of its motion:

$$E_{\text{tot}} = \tfrac{1}{2}kA^2 \Rightarrow A = \sqrt{\frac{2E_{\text{tot}}}{k}}$$

Substitute numerical values and evaluate *A*:

$$A = \sqrt{\frac{2(0.90\,\text{J})}{2000\,\text{N/m}}} = \boxed{3.0\,\text{cm}}$$

(*b*) Express the total mechanical energy of the object in terms of its maximum speed:

$$E_{\text{tot}} = \tfrac{1}{2}mv_{\text{max}}^2 \Rightarrow v_{\text{max}} = \sqrt{\frac{2E_{\text{tot}}}{m}}$$

Substitute numerical values and evaluate v_{max}:

$$v_{\text{max}} = \sqrt{\frac{2(0.90\,\text{J})}{3.0\,\text{kg}}} = \boxed{77\,\text{cm/s}}$$

45 • An object on a frictionless horizontal surface oscillates at the end of a spring with an amplitude of 4.5 cm. Its total mechanical energy is 1.4 J. What is the force constant of the spring?

Picture the Problem The total mechanical energy of the object is given by $E_{\text{tot}} = \tfrac{1}{2}kA^2$. We can solve this equation for the force constant *k* and substitute the numerical data to determine its value.

Express the total mechanical energy of the oscillator as a function of the amplitude of its motion:

$$E_{tot} = \tfrac{1}{2}kA^2 \Rightarrow k = \frac{2E_{tot}}{A^2}$$

Substitute numerical values and evaluate k:

$$k = \frac{2(1.4\,\text{J})}{(0.045\,\text{m})^2} = \boxed{1.4\ \text{kN/m}}$$

46 •• A 3.0-kg object on a frictionless horizontal surface oscillates at the end of a spring with an amplitude of 8.0 cm. Its maximum acceleration is 3.5 m/s^2. Find the total mechanical energy.

Picture the Problem The total mechanical energy of the system is the sum of the potential and kinetic energies. That is, $E_{tot} = \tfrac{1}{2}kx^2 + \tfrac{1}{2}mv^2$. Newton's second law relates the acceleration to the displacement. That is, $-kx = ma$. In addition, when $x = A$, $v = 0$. Use these equations to solve E_{tot} in terms of the given parameters m, A and a_{max}.

The total mechanical energy is the sum of the potential and kinetic energies. We don't know k so we need an equation relating k to one or more of the given parameters:

$$E_{tot} = \tfrac{1}{2}kx^2 + \tfrac{1}{2}mv^2$$

The force exerted by the spring equals the mass of the object multiplied by its acceleration:

$$-kx = ma \Rightarrow k = -\frac{ma}{x}$$

When $x = -A$, $a = a_{max}$. Thus,

$$k = -\frac{ma_{max}}{-A} = \frac{ma_{max}}{A}$$

Substitute to obtain:

$$E_{tot} = \tfrac{1}{2}\frac{ma_{max}}{A}x^2 + \tfrac{1}{2}mv^2$$

When $x = A$, $v = 0$. Substitute to obtain:

$$E_{tot} = \tfrac{1}{2}\frac{ma_{max}}{A}A^2 + 0 = \tfrac{1}{2}ma_{max}A$$

Substitute numerical values and evaluate E_{tot}:

$$E_{tot} = \tfrac{1}{2}(3.0\,\text{kg})(3.5\,\text{m/s}^2)(0.080\,\text{m}) = \boxed{0.42\,\text{J}}$$

Simple Harmonic Motion and Springs

47 • A 2.4-kg object on a frictionless horizontal surface is attached to a horizontal spring that has a force constant 4.5 kN/m. The spring is stretched 10 cm from equilibrium and released. What are (*a*) the frequency of the motion, (*b*) the period, (*c*) the amplitude, (*d*) the maximum speed, and (*e*) the maximum acceleration? (*f*) When does the object first reach its equilibrium position? What is its acceleration at this time?

Picture the Problem The frequency of the object's motion is given by $f = \dfrac{1}{2\pi}\sqrt{k/m}$ and its period is the reciprocal of *f*. The maximum velocity and acceleration of an object executing simple harmonic motion are $v_{max} = A\omega$ and $a_{max} = A\omega^2$, respectively.

(*a*) The frequency of the motion is given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi}\sqrt{\frac{4.5\,\text{kN/m}}{2.4\,\text{kg}}} = 6.89\ \text{Hz} = \boxed{6.9\,\text{Hz}}$$

(*b*) The period of the motion to is the reciprocal of its frequency:

$$T = \frac{1}{f} = \frac{1}{6.89\,\text{s}^{-1}} = 0.145\ \text{s} = \boxed{0.15\,\text{s}}$$

(*c*) Because the object is released from rest after the spring to which it is attached is stretched 10 cm:

$$A = \boxed{10\,\text{cm}}$$

(*d*) The object's maximum speed is given by:

$$v_{max} = A\omega = 2\pi f A$$

Substitute numerical values and evaluate v_{max}:

$$v_{max} = 2\pi\left(6.89\,\text{s}^{-1}\right)\left(0.10\,\text{m}\right) = 4.33\,\text{m/s} = \boxed{4.3\,\text{m/s}}$$

(*e*) The object's maximum acceleration is given by:

$$a_{max} = A\omega^2 = \omega v_{max} = 2\pi f v_{max}$$

Substitute numerical values and evaluate a_{max}:

$$a_{max} = 2\pi\left(6.89\,\text{s}^{-1}\right)\left(4.33\,\text{m/s}\right) = \boxed{1.9\times10^{2}\ \text{m/s}^{2}}$$

(*f*) The object first reaches its equilibrium when:

$$t = \tfrac{1}{4}T = \tfrac{1}{4}\left(0.145\,\text{s}\right) = \boxed{36\,\text{ms}}$$

Because the resultant force acting on the object as it passes through its equilibrium position is zero, the acceleration of the object is:

$$a = \boxed{0}$$

48 • A 5.00-kg object on a frictionless horizontal surface is attached to one end of a horizontal spring that has a force constant k = 700 N/m. The spring is stretched 8.00 cm from equilibrium and released. What are (*a*) the frequency of the motion, (*b*) the period, (*c*) the amplitude, (*d*) the maximum speed, and (*e*) the maximum acceleration? (*f*) When does the object first reach its equilibrium position? What is its acceleration at this time?

Picture the Problem The frequency of the object's motion is given by $f = \frac{1}{2\pi}\sqrt{k/m}$ and its period is the reciprocal of *f*. The maximum speed and acceleration of an object executing simple harmonic motion are $v_{max} = A\omega$ and $a_{max} = A\omega^2$, respectively.

(*a*) The frequency of the motion is given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi}\sqrt{\frac{700\,\text{N/m}}{5.00\,\text{kg}}} = 1.883\,\text{Hz} = \boxed{1.88\,\text{Hz}}$$

(*b*) The period of the motion is the reciprocal of its frequency:

$$T = \frac{1}{f} = \frac{1}{1.883\,\text{s}^{-1}} = 0.5310\,\text{s} = \boxed{0.531\,\text{s}}$$

(*c*) Because the object is released from rest after the spring to which it is attached is stretched 8.00 cm:

$$A = \boxed{8.00\,\text{cm}}$$

(*d*) The object's maximum speed is given by:

$$v_{max} = A\omega = 2\pi f A$$

Substitute numerical values and evaluate v_{max}:

$$v_{max} = 2\pi\left(1.883\,s^{-1}\right)\left(0.0800\,m\right) = 0.9465\,m/s = \boxed{0.947\,m/s}$$

(*e*) The object's maximum acceleration is given by:

$$a_{max} = A\omega^2 = \omega v_{max} = 2\pi f v_{max}$$

Substitute numerical values and evaluate a_{max}:

$$a_{max} = 2\pi\left(1.883\,s^{-1}\right)\left(0.9465\,m/s\right) = \boxed{11.2\,m/s^2}$$

(*f*) The object first reaches its equilibrium when:

$$t = \tfrac{1}{4}T = \tfrac{1}{4}\left(0.5310\,s\right) = \boxed{0.133\,s}$$

Because the resultant force acting on the object as it passes through its equilibrium point is zero, the acceleration of the object is $a = \boxed{0.}$

49 • [SSM] A 3.0-kg object on a frictionless horizontal surface is attached to one end of a horizontal spring and oscillates with an amplitude A = 10 cm and a frequency 2.4 Hz. (*a*) What is the force constant of the spring? (*b*) What is the period of the motion? (*c*) What is the maximum speed of the object? (*d*) What is the maximum acceleration of the object?

Picture the Problem (*a*) The angular frequency of the motion is related to the force constant of the spring through $\omega^2 = k/m$. (*b*) The period of the motion is the reciprocal of its frequency. (*c*) and (*d*) The maximum speed and acceleration of an object executing simple harmonic motion are $v_{max} = A\omega$ and $a_{max} = A\omega^2$, respectively.

(*a*) Relate the angular frequency of the motion to the force constant of the spring:

$$\omega^2 = \frac{k}{m} \Rightarrow k = m\omega^2 = 4\pi^2 f^2 m$$

Substitute numerical values to obtain:

$$k = 4\pi^2\left(2.4\,s^{-1}\right)^2\left(3.0\,kg\right) = 682\,N/m = \boxed{0.68\,kN/m}$$

(*b*) Relate the period of the motion to its frequency:

$$T = \frac{1}{f} = \frac{1}{2.4\,\text{s}^{-1}} = 0.417\,\text{s} = \boxed{0.42\,\text{s}}$$

(*c*) The maximum speed of the object is given by:

$$v_{\max} = A\omega = 2\pi f A$$

Substitute numerical values and evaluate $v_{\max}$:

$$v_{\max} = 2\pi\left(2.4\,\text{s}^{-1}\right)\left(0.10\,\text{m}\right) = 1.51\,\text{m/s} = \boxed{1.5\,\text{m/s}}$$

(*d*) The maximum acceleration of the object is given by:

$$a_{\max} = A\omega^2 = 4\pi^2 f^2 A$$

Substitute numerical values and evaluate $a_{\max}$:

$$a_{\max} = 4\pi^2\left(2.4\,\text{s}^{-1}\right)^2\left(0.10\,\text{m}\right) = \boxed{23\,\text{m/s}^2}$$

50 • An 85.0-kg person steps into a car of mass 2400 kg, causing it to sink 2.35 cm on its springs. If started into vertical oscillation, and assuming no damping, at what frequency will the car and passenger vibrate on these springs?

Picture the Problem We can find the frequency of vibration of the car-and-passenger system using $f = \frac{1}{2\pi}\sqrt{\frac{k}{M}}$, where M is the total mass of the system. The force constant of the spring can be determined from the compressing force and the amount of compression.

Express the frequency of the car-and-passenger system:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{M}}$$

The force constant is given by:

$$k = \frac{F}{\Delta x} = \frac{mg}{\Delta x}$$

where m is the person's mass.

Substitute for k in the expression for f to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{mg}{M\Delta x}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi}\sqrt{\frac{\left(85.0\,\text{kg}\right)\left(9.81\,\text{m/s}^2\right)}{\left(2485\,\text{kg}\right)\left(2.35\times10^{-2}\,\text{m}\right)}} = \boxed{0.601\,\text{Hz}}$$

51 • A 4.50-kg object oscillates on a horizontal spring with an amplitude of 3.80 cm. The object's maximum acceleration is 26.0 m/s^2. Find (*a*) the force constant of the spring, (*b*) the frequency of the object, and (*c*) the period of the motion of the object.

Picture the Problem (*a*) We can relate the force constant *k* to the maximum acceleration by eliminating ω^2 between $\omega^2 = k/m$ and $a_{max} = A\omega^2$. (*b*) We can find the frequency *f* of the motion by substituting ma_{max}/A for *k* in $f = \frac{1}{2\pi}\sqrt{k/m}$. (*c*) The period of the motion is the reciprocal of its frequency. Assume that friction is negligible.

(*a*) Relate the angular frequency of the motion to the force constant and the mass of the oscillator:

$$\omega^2 = \frac{k}{m} \Rightarrow k = \omega^2 m$$

Relate the object's maximum acceleration to its angular frequency and amplitude and solve for the square of the angular frequency:

$$a_{max} = A\omega^2 \Rightarrow \omega^2 = \frac{a_{max}}{A} \qquad (1)$$

Substitute for ω^2 to obtain:

$$k = \frac{ma_{max}}{A}$$

Substitute numerical values and evaluate *k*:

$$k = \frac{(4.50\,\text{kg})(26.0\,\text{m/s}^2)}{3.80\times10^{-2}\,\text{m}} = \boxed{3.08\,\text{kN/m}}$$

(*b*) Replace ω in equation (1) by $2\pi f$ and solve for f to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{a_{max}}{A}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi}\sqrt{\frac{26.0\,\text{m/s}^2}{3.80\times10^{-2}\,\text{m}}} = 4.163\,\text{Hz} = \boxed{4.16\,\text{Hz}}$$

(*c*) The period of the motion is the reciprocal of its frequency:

$$T = \frac{1}{f} = \frac{1}{4.163\,\text{s}^{-1}} = \boxed{0.240\,\text{s}}$$

52 •• An object of mass *m* is suspended from a vertical spring of force constant 1800 N/m. When the object is pulled down 2.50 cm from equilibrium and released from rest, the object oscillates at 5.50 Hz. (*a*) Find *m*. (*b*) Find the amount the spring is stretched from its unstressed length when the object is in

equilibrium. (*c*) Write expressions for the displacement x, the velocity v_x, and the acceleration a_x as functions of time t.

Picture the Problem Choose a coordinate system in which upward is the $+y$ direction. We can find the mass of the object using $m = k/\omega^2$. We can apply a condition for translational equilibrium to the object when it is at its equilibrium position to determine the amount the spring has stretched from its natural length. Finally, we can use the initial conditions to determine A and δ and express $x(t)$ and then differentiate this expression to obtain $v_x(t)$ and $a_x(t)$.

(*a*) Express the angular frequency of the system in terms of the mass of the object fastened to the vertical spring and solve for the mass of the object:

$$\omega^2 = \frac{k}{m} \Rightarrow m = \frac{k}{\omega^2}$$

Express ω^2 in terms of f:

$$\omega^2 = 4\pi^2 f^2$$

Substitute for $\boldsymbol{\omega}^2$ to obtain:

$$m = \frac{k}{4\pi^2 f^2}$$

Substitute numerical values and evaluate m:

$$m = \frac{1800\,\text{N/m}}{4\pi^2\left(5.50\,\text{s}^{-1}\right)^2} = 1.507\text{ kg}$$

$$= \boxed{1.51\,\text{kg}}$$

(*b*) Letting Δx represent the amount the spring is stretched from its natural length when the object is in equilibrium, apply $\sum F_y = 0$ to the object when it is in equilibrium:

$$k\Delta x - mg = 0 \Rightarrow \Delta x = \frac{mg}{k}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{(1.507\text{ kg})\left(9.81\,\text{m/s}^2\right)}{1800\text{ N/m}} = \boxed{8.21\,\text{mm}}$$

(*c*) Express the position of the object as a function of time:

$$x = A\cos(\omega t + \delta)$$

Use the initial conditions $x_0 = -2.50$ cm and $v_0 = 0$ to find δ:

$$\delta = \tan^{-1}\left(-\frac{v_0}{\omega x_0}\right) = \tan^{-1}(0) = \pi$$

Evaluate ω:

$$\omega = \sqrt{\frac{k}{m}} = \sqrt{\frac{1800\,\text{N/m}}{1.507\,\text{kg}}} = 34.56\,\text{rad/s}$$

Substituting numerical values in the expression for x gives:

$$x = (2.50\,\text{cm})\cos[(34.56\,\text{rad/s})t + \pi] = \boxed{-(2.50\,\text{cm})\cos[(34.6\,\text{rad/s})t]}$$

Differentiate $x(t)$ to obtain v_x:

$$v_x = (86.39\,\text{cm/s})\sin[(34.56\,\text{rad/s})t] = \boxed{(86.4\,\text{cm/s})\sin[(34.6\,\text{rad/s})t]}$$

Differentiate $v(t)$ to obtain a_x:

$$a_x = (29.86\,\text{m/s}^2)\cos[(34.56\,\text{rad/s})t] = \boxed{(29.9\,\text{m/s}^2)\cos[(34.6\,\text{rad/s})t]}$$

53 •• An object is hung on the end of a vertical spring and is released from rest with the spring unstressed. If the object falls 3.42 cm before first coming to rest, find the period of the resulting oscillatory motion.

Picture the Problem Let the system include the object and the spring. Then, the net external force acting on the system is zero. Choose E_i = 0 and apply the conservation of mechanical energy to the system.

Express the period of the motion in terms of its angular frequency:

$$T = \frac{2\pi}{\omega} \qquad (1)$$

Apply conservation of energy to the system:

$$E_\text{i} = E_\text{f} \Rightarrow 0 = U_\text{g} + U_\text{spring}$$

Substituting for U_g and U_spring yields:

$$0 = -mg\Delta x + \tfrac{1}{2}k(\Delta x)^2 \Rightarrow \frac{k}{m} = \frac{2g}{\Delta x}$$

and $\omega = \sqrt{\frac{k}{m}} = \sqrt{\frac{2g}{\Delta x}}$

Substituting for ω in equation (1) and simplifying yields:

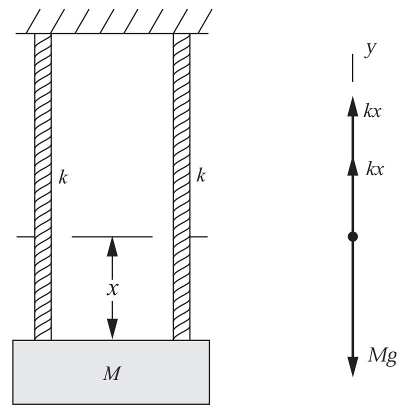
$$T = \frac{2\pi}{\sqrt{\frac{2g}{\Delta x}}} = 2\pi\sqrt{\frac{\Delta x}{2g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{3.42\,\text{cm}}{2(9.81\,\text{m/s}^2)}} = \boxed{0.262\,\text{s}}$$

54 •• A suitcase of mass 20 kg is hung from two bungee cords, as shown in Figure 14-27. Each cord is stretched 5.0 cm when the suitcase is in equilibrium. If the suitcase is pulled down a little and released, what will be its oscillation frequency?

Picture the Problem The diagram shows the stretched bungee cords supporting the suitcase under equilibrium conditions. We can use $f = \frac{1}{2\pi}\sqrt{\frac{k_{\text{eff}}}{M}}$ to express the frequency of the suitcase in terms of the effective ″spring″ constant k_{eff} and apply the condition for translational equilibrium to the suitcase to find k_{eff}.



Express the frequency of the suitcase oscillator:

$$f = \frac{1}{2\pi}\sqrt{\frac{k_{\text{eff}}}{M}} \qquad (1)$$

Apply $\sum F_y = 0$ to the suitcase to obtain:

$$kx + kx - Mg = 0$$

or

$$2kx - Mg = 0$$

or

$$k_{\text{eff}}x - Mg = 0 \Rightarrow k_{\text{eff}} = \frac{Mg}{x}$$

where $k_{\text{eff}} = 2k$

Substitute for k_{eff} in equation (1) to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{g}{x}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi}\sqrt{\frac{9.81\,\text{m/s}^2}{0.050\,\text{m}}} = \boxed{2.2\,\text{Hz}}$$

55 •• A 0.120-kg block is suspended from a spring. When a small pebble of mass 30 g is placed on the block, the spring stretches an additional 5.0 cm. With the pebble on the block, the spring oscillates with an amplitude of 12 cm. (*a*) What is the frequency of the motion? (*b*) How long does the block take to travel from its lowest point to its highest point? (*c*) What is the net force on the pebble when it is at the point of maximum upward displacement?

Picture the Problem (*a*) The frequency of the motion of the pebble and block depends on the force constant of the spring and the mass of the pebble plus block. The force constant can be determined from the equilibrium of the system when

the spring is stretched additionally by the addition of the pebble to the block.
(*b*) The time required for the block to travel from its lowest point to its highest point is half its period. (*c*) We can apply Newton's second law to the pebble to find the net force on the pebble when it is at the point of maximum upward displacement.

(*a*) Express the frequency of the motion in terms of k and m_{tot}:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m_{tot}}} \qquad (1)$$

where m_{tot} is the total mass suspended from the spring.

Apply $\sum F_y = 0$ to the pebble when it is at its equilibrium position:

$$k\Delta y - mg = 0 \Rightarrow k = \frac{mg}{\Delta y}$$

Substitute for k in equation (1) to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{mg}{\Delta y m_{tot}}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi}\sqrt{\frac{(0.030\ \text{kg})(9.81\ \text{m/s}^2)}{(0.050\ \text{m})(0.15\ \text{kg})}} = 0.997\ \text{Hz} = \boxed{1.0\ \text{Hz}}$$

(*b*) The time it takes for the block to travel from its lowest point to its highest point is one-half its period:

$$t = \tfrac{1}{2}T = \frac{1}{2f} = \frac{1}{2(0.997\ \text{s}^{-1})} = \boxed{0.50\ \text{s}}$$

(*c*) Apply $\sum F_y = 0$ to the pebble when it is at the point of maximum upward displacement:

$$F_{net} = ma_{max} = -m(-\omega^2 A) = m\omega^2 A = m(2\pi f)^2 A = 4\pi^2 f^2 mA$$

Substituting for ω and simplifying gives:

$$F_{net} = m(2\pi f)^2 A = 4\pi^2 f^2 mA$$

Substitute numerical values and evaluate F_{net}:

$$F_{net} = 4\pi^2 (0.997\ \text{s}^{-1})^2 (0.030\ \text{kg})(0.12\ \text{m}) = \boxed{0.14\ \text{N}}$$

56 •• Referring to Problem 55, find the maximum amplitude of oscillation at which the pebble will remain in contact with the block.

Picture the Problem We can use the maximum acceleration of the oscillator to express a_{max} in terms of A, k, and m. k can be determined from the equilibrium of the system when the spring is stretched additionally by the addition of the stone to the mass. If the stone is to remain in contact with the block, the block's maximum downward acceleration must not exceed g.

Express the maximum acceleration of the oscillator in terms of its angular frequency and amplitude of the motion:

$$a_{max} = A\omega^2$$

Relate ω^2 to the force constant of the spring and the mass of the block-plus-stone:

$$\omega^2 = \frac{k}{m_{tot}}$$

Substitute for ω^2 to obtain:

$$a_{max} = A\frac{k}{m_{tot}} \qquad (1)$$

Apply $\sum F_y = 0$ to the stone when it is at its equilibrium position:

$$k\Delta y - mg = 0 \Rightarrow k = \frac{mg}{\Delta y}$$

where Δy is the additional distance the spring stretched when the stone was placed on the block.

Substitute for k in equation (1) to obtain:

$$a_{max} = A\left(\frac{mg}{\Delta y m_{tot}}\right)$$

Set $a_{max} = g$ and solve for A_{max}:

$$A_{max} = \frac{\Delta y m_{tot}}{mg}g = \frac{m_{tot}}{m}\Delta y$$

Substitute numerical values and evaluate A_{max}:

$$A_{max} = \left(\frac{0.15\text{ kg}}{0.030\text{ kg}}\right)(0.050\text{ m}) = \boxed{25\text{ cm}}$$

57 •• An object of mass 2.0 kg is attached to the top of a vertical spring that is anchored to the floor. The unstressed length of the spring is 8.0 cm and the length of the spring when the object is in equilibrium is 5.0 cm. When the object is resting at its equilibrium position, it is given a sharp downward blow with a hammer so that its initial speed is 0.30 m/s. (*a*) To what maximum height above the floor does the object eventually rise? (*b*) How long does it take for the object to reach its maximum height for the first time? (*c*) Does the spring ever become unstressed? What minimum initial speed must be given to the object for the spring to be unstressed at some time?

Picture the Problem (*a*) The maximum height above the floor to which the object rises is the sum of its initial distance from the floor and the amplitude of its motion. We can find the amplitude of its motion by relating it to the object's maximum speed. (*b*) Because the object initially travels downward, it will be three-fourths of the way through its cycle when it first reaches its maximum height. (*c*) We can find the minimum initial speed the object would need to be given in order for the spring to become uncompressed by applying conservation of mechanical energy.

(*a*) Relate *h*, the maximum height above the floor to which the object rises, to the amplitude of its motion:

$$h = A + 5.0\ \text{cm} \qquad (1)$$

Relate the maximum speed of the object to the angular frequency and amplitude of its motion and solve for the amplitude:

$$v_{\text{max}} = A\omega$$

or, because $\omega^2 = \dfrac{k}{m}$,

$$A = v_{\text{max}}\sqrt{\frac{m}{k}} \qquad (2)$$

Apply $\sum F_y = 0$ to the object when it is resting at its equilibrium position to obtain:

$$k\Delta y - mg = 0 \Rightarrow k = \frac{mg}{\Delta y}$$

Substitute for k in equation (2):

$$A = v_{\text{max}}\sqrt{\frac{m\Delta y}{mg}} = v_{\text{max}}\sqrt{\frac{\Delta y}{g}}$$

Substituting for A in equation (1) yields:

$$h = v_{\text{max}}\sqrt{\frac{\Delta y}{g}} + 5.0\ \text{cm}$$

Substitute numerical values and evaluate *h*:

$$h = 0.30\ \text{m/s}^2\sqrt{\frac{0.030\ \text{m}}{9.81\ \text{m/s}^2}} + 5.0\ \text{cm}$$

$$= \boxed{6.7\ \text{cm}}$$

(*b*) The time required for the object to reach its maximum height the first time is three-fourths its period:

$$t = \tfrac{3}{4}T$$

Express the period of the motion of the oscillator:

$$T = 2\pi\sqrt{\frac{m}{k}} = 2\pi\sqrt{\frac{m}{\frac{mg}{\Delta y}}} = 2\pi\sqrt{\frac{\Delta y}{g}}$$

Substitute for T in the expression for t to obtain:

$$t = \frac{3}{4}\left(2\pi\sqrt{\frac{\Delta y}{g}}\right) = \frac{3\pi}{2}\sqrt{\frac{\Delta y}{g}}$$

Substitute numerical values and evaluate t:

$$t = \frac{3\pi}{2}\sqrt{\frac{0.030\ \text{m}}{9.81\ \text{m/s}^2}} = \boxed{0.26\ \text{s}}$$

(c) Because $h < 8.0$ cm, the spring is never uncompressed.

Using conservation of energy and letting U_g be zero 5 cm above the floor, relate the height to which the object rises, Δy, to its initial kinetic energy:

$$\Delta K + \Delta U_g + \Delta U_s = 0$$

or, because $K_f = U_i = 0$,

$$\tfrac{1}{2}mv_i^2 - mg\Delta y + \tfrac{1}{2}k(\Delta y)^2 - \tfrac{1}{2}k(L - y_i)^2 = 0$$

Because $\Delta y = L - y_i$:

$$\tfrac{1}{2}mv_i^2 - mg\Delta y + \tfrac{1}{2}k(\Delta y)^2 - \tfrac{1}{2}k(\Delta y)^2 = 0$$

and

$$\tfrac{1}{2}mv_i^2 - mg\Delta y = 0 \Rightarrow v_i = \sqrt{2g\Delta y}$$

Substitute numerical values and evaluate v_i:

$$v_i = \sqrt{2(9.81\ \text{m/s}^2)(3.0\ \text{cm})} = 77\ \text{cm/s}$$

That is, the minimum initial speed that must be given to the object for the spring to be uncompressed at some time is $\boxed{77\ \text{cm/s}}$

58 ••• A winch cable has a cross-sectional area of 1.5 cm^2 and a length of 2.5 m. Young's modulus for the cable is 150 GN/m^2. A 950-kg engine block is hung from the end of the cable. (a) By what length does the cable stretch? (b) If we treat the cable as a simple spring, what is the oscillation frequency of the engine block at the end of the cable?

Picture the Problem We can relate the elongation of the cable to the load on it using the definition of Young's modulus and use the expression for the frequency of a spring-mass oscillator to find the oscillation frequency of the engine block at the end of the wire.

(*a*) Using the definition of Young's modulus, relate the elongation of the cable to the applied stress:

$$Y = \frac{\text{stress}}{\text{strain}} = \frac{F/A}{\Delta\ell/\ell} \Rightarrow \Delta\ell = \frac{F\ell}{AY} = \frac{Mg\ell}{AY}$$

Substitute numerical values and evaluate $\Delta\ell$:

$$\Delta\ell = \frac{(950\,\text{kg})(9.81\,\text{m/s}^2)(2.5\,\text{m})}{(1.5\,\text{cm}^2)(150\,\text{GN/m}^2)} = 1.0355\,\text{mm} = \boxed{1.0\,\text{mm}}$$

(*b*) Express the oscillation frequency of the wire-engine block system:

$$f = \frac{1}{2\pi}\sqrt{\frac{k_{\text{eff}}}{M}}$$

Express the effective ″spring″ constant of the cable:

$$k_{\text{eff}} = \frac{F}{\Delta\ell} = \frac{Mg}{\Delta\ell}$$

Substitute for k_{eff} to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{g}{\Delta\ell}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi}\sqrt{\frac{9.81\,\text{m/s}^2}{1.0355\,\text{mm}}} = \boxed{15\,\text{Hz}}$$

Simple Pendulum Systems

59 • **[SSM]** Find the length of a simple pendulum if its frequency for small amplitudes is 0.75 Hz.

Picture the Problem The frequency of a simple pendulum depends on its length and on the local gravitational field and is given by $f = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$.

The frequency of a simple pendulum oscillating with small amplitude is given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{g}{L}} \Rightarrow L = \frac{g}{4\pi^2 f^2}$$

Substitute numerical values and evaluate *L*:

$$L = \frac{9.81\,\text{m/s}^2}{4\pi^2\left(0.75\,\text{s}^{-1}\right)^2} = \boxed{44\,\text{cm}}$$

60 • Find the length of a simple pendulum if its period for small amplitudes is 5.0 s.

Picture the Problem We can determine the required length of the pendulum from the expression for the period of a simple pendulum.

Express the period of a simple pendulum:

$$T = 2\pi\sqrt{\frac{L}{g}} \Rightarrow L = \frac{T^2 g}{4\pi^2}$$

Substitute numerical values and evaluate L:

$$L = \frac{(5.0\,\text{s})^2(9.81\,\text{m/s}^2)}{4\pi^2} = \boxed{6.2\,\text{m}}$$

61 • What would be the period of the pendulum in Problem 60 if the pendulum were on the moon, where the acceleration due to gravity is one-sixth that on Earth?

Picture the Problem We can find the period of the pendulum from $T = 2\pi\sqrt{L/g_{\text{moon}}}$ where $g_{\text{moon}} = \frac{1}{6}g$ and L = 6.21 m.

Express the period of a simple pendulum on the moon:

$$T = 2\pi\sqrt{\frac{L}{g_{\text{moon}}}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{6.21\,\text{m}}{\frac{1}{6}(9.81\,\text{m/s}^2)}} = \boxed{12\,\text{s}}$$

62 • If the period of a 70.0-cm-long simple pendulum is 1.68 s, what is the value of g at the location of the pendulum?

Picture the Problem We can find the value of g at the location of the pendulum by solving the equation $T = 2\pi\sqrt{L/g}$ for g and evaluating it for the given length and period.

Express the period of a simple pendulum where the gravitational field is g:

$$T = 2\pi\sqrt{\frac{L}{g}} \Rightarrow g = \frac{4\pi^2 L}{T^2}$$

Substitute numerical values and evaluate g:

$$g = \frac{4\pi^2(0.700\,\text{m})}{(1.68\,\text{s})^2} = \boxed{9.79\,\text{m/s}^2}$$

63 • A simple pendulum set up in the stairwell of a 10-story building consists of a heavy weight suspended on a 34.0-m-long wire. What is the period of oscillation?

Picture the Problem We can use $T = 2\pi\sqrt{L/g}$ to find the period of this pendulum.

Express the period of a simple pendulum:

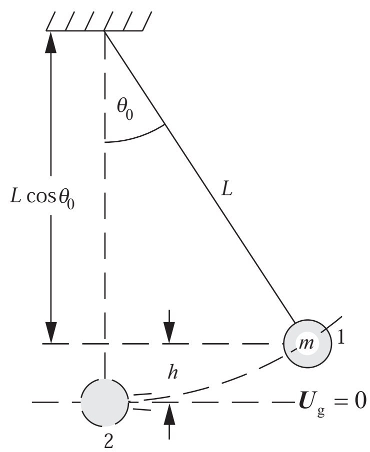
$$T = 2\pi\sqrt{\frac{L}{g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{34.0\,\text{m}}{9.81\,\text{m/s}^2}} = \boxed{11.7\,\text{s}}$$

64 •• Show that the total energy of a simple pendulum undergoing oscillations of small amplitude ϕ_0 (in radians) is $E \approx \frac{1}{2}mgL\phi_0^2$. *Hint: Use the approximation* $\cos\phi \approx 1 - \frac{1}{2}\phi^2$ *for small* ϕ.

Picture the Problem The figure shows the simple pendulum at maximum angular displacement ϕ_0. The total energy of the simple pendulum is equal to its initial gravitational potential energy. We can apply the definition of gravitational potential energy and use the small-angle approximation to show that $E \approx \frac{1}{2}mgL\phi_0^2$.



Express the total energy of the simple pendulum at maximum displacement:

$$E = U_{\text{max displacement}} = mgh$$

Referring to the diagram, express h in terms of L and ϕ_0:

$$h = L - L\cos\phi_0 = L(1 - \cos\phi_0)$$

Substituting for h yields:

$$E = mgL[1 - \cos\phi_0]$$

From the power series expansion for $\cos\phi$, for $\phi << 1$:

$$\cos\phi \approx 1 - \tfrac{1}{2}\phi^2$$

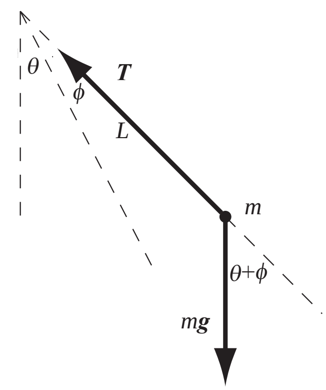
Substitute and simplify to obtain:

$$E = mgL\left[1 - \left(1 - \tfrac{1}{2}\phi_0^2\right)\right] = \boxed{\tfrac{1}{2}mgL\phi_0^2}$$

65 ••• **[SSM]** A simple pendulum of length L is attached to a massive cart that slides without friction down a plane inclined at angle θ with the horizontal, as shown in Figure 14-28. Find the period of oscillation for small oscillations of this pendulum.

Picture the Problem The cart accelerates down the ramp with a constant acceleration of $g\sin\theta$. This happens because the cart is much more massive than the bob, so the motion of the cart is unaffected by the motion of the bob oscillating back and forth. The path of the bob is quite complex in the reference frame of the ramp, but in the reference frame moving with the cart the path of the bob is much simpler—in this frame the bob moves back and forth along a circular arc. To solve this problem we first apply Newton's second law (to the bob) in the inertial reference frame of the ramp. Then we transform to the reference frame moving with the cart in order to exploit the simplicity of the motion in that frame.

Draw the free-body diagram for the bob. Let ϕ denote the angle that the string makes with the normal to the ramp. The forces on the bob are the tension force and the force of gravity:



Apply Newton's second law to the bob, labeling the acceleration of the bob relative to the ramp $\vec{a}_{\mathrm{BR}}$:

$$\vec{T} + m\vec{g} = m\vec{a}_{\mathrm{BR}}$$

The acceleration of the bob relative to the ramp is equal to the acceleration of the bob relative to the cart plus the acceleration of the cart relative to the ramp:

$$\vec{a}_{\mathrm{BR}} = \vec{a}_{\mathrm{BC}} + \vec{a}_{\mathrm{CR}}$$

Substitute for $\vec{a}_{\mathrm{BR}}$ in $\vec{T} + m\vec{g} = m\vec{a}_{\mathrm{BR}}$:

$$\vec{T} + m\vec{g} = m\left(\vec{a}_{\mathrm{BC}} + \vec{a}_{\mathrm{CR}}\right)$$

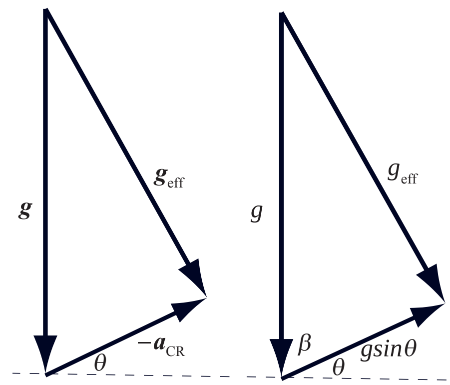
Rearrange terms and label $\vec{g} - \vec{a}_{\mathrm{CR}}$ as $\vec{g}_{\mathrm{eff}}$, where $\vec{g}_{\mathrm{eff}}$ is the acceleration, relative to the cart, of an object in free fall. (If the tension force is set to zero the bob is in free fall.):

$$\vec{T} + m\left(\vec{g} - \vec{a}_{\mathrm{CR}}\right) = m\vec{a}_{\mathrm{BC}}$$

Label $\vec{g} - \vec{a}_{\mathrm{CR}}$ as $\vec{g}_{\mathrm{eff}}$ to obtain

$$\vec{T} + m\vec{g}_{\mathrm{eff}} = m\vec{a}_{\mathrm{BC}} \qquad (1)$$

To find the magnitude of $\vec{g}_{\text{eff}}$, first draw the vector addition diagram representing the equation $\vec{g}_{\text{eff}} = \vec{g} - \vec{a}_{\text{CR}}$. Recall that $a_{\text{CR}} = g\sin\theta$:



From the diagram, find the magnitude of $\vec{g}_{\text{eff}}$. Use the law of cosines to obtain:

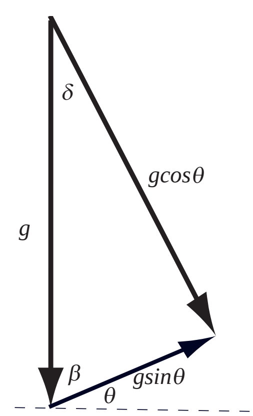
$$g_{\text{eff}}^2 = g^2 + g^2\sin^2\theta - 2g(g\sin\theta)\cos\beta$$

But $\cos\beta = \sin\theta$, so

$$\begin{aligned} g_{\text{eff}}^2 &= g^2 + g^2\sin^2\theta - 2g^2\sin^2\theta \\ &= g^2(1-\sin^2\theta) = g^2\cos^2\theta \end{aligned}$$

Thus $g_{\text{eff}} = g\cos\theta$

To find the direction of $\vec{g}_{\text{eff}}$, first redraw the vector addition diagram as shown:

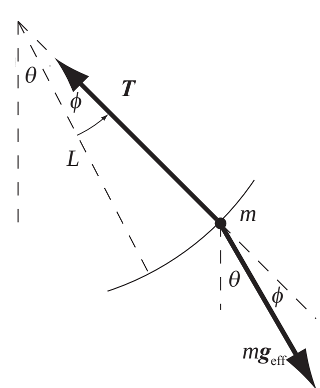


From the diagram find the direction of $\vec{g}_{\text{eff}}$. Use the law of cosines again and solve for δ:

$$g^2\sin^2\theta = g^2 + g^2\cos^2\theta - 2g^2\cos\theta\cos\delta$$

and so $\delta = \theta$

To find an equation for the motion of the bob draw the free-body diagram for the "forces" that appear in equation (1). Draw the path of the bob in the reference frame moving with the cart:



Take the tangential components of each vector in equation (1) in the frame of the cart yields. The tangential component of the acceleration is equal to the radius of the circle times the angular acceleration $(a_t = r\alpha)$:

$$0 - mg_{\text{eff}}\sin\phi = mL\frac{d^2\phi}{dt^2}$$

where L is the length of the string and $\frac{d^2\phi}{dt^2}$ is the angular acceleration of the bob. The positive tangential "direction" is counterclockwise.

Rearranging this equation yields:

$$mL\frac{d^2\phi}{dt^2} + mg_{\text{eff}}\sin\phi = 0 \qquad (2)$$

For small oscillations of the pendulum:

$|\phi| << 1$ and $\sin\phi \approx \phi$

Substituting for $\sin\phi$ in equation (2) yields:

$$mL\frac{d^2\phi}{dt^2} + mg_{\text{eff}}\phi = 0$$

or

$$\frac{d^2\phi}{dt^2} + \frac{g_{\text{eff}}}{L}\phi = 0 \qquad (3)$$

Equation (3) is the equation of motion for simple harmonic motion with angular frequency:

$$\omega = \sqrt{\frac{g_{\text{eff}}}{L}}$$

where ω is the angular frequency of the oscillations (and not the angular speed of the bob).

The period of this motion is:

$$T = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{L}{g_{\text{eff}}}} \qquad (4)$$

Substitute $g\cos\theta$ for g_{eff} in equation (4) to obtain:

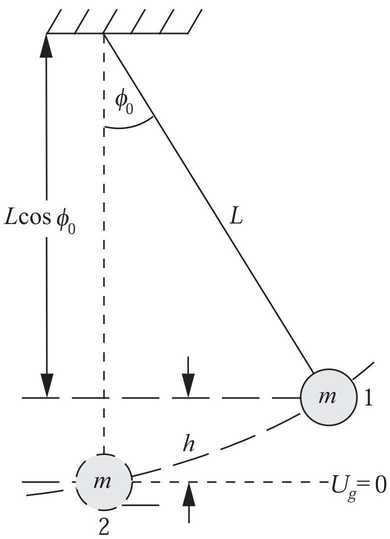
$$T = 2\pi\sqrt{\frac{L}{g_{\text{eff}}}} = \boxed{2\pi\sqrt{\frac{L}{g\cos\theta}}}$$

Remarks: Note that, in the limiting case $\theta = 0$, $T = 2\pi\sqrt{L/g}$. As $\theta \to 90°$, $T \to \infty$.

66 ••• The bob at the end of a simple pendulum of length L is released from rest from an angle ϕ_0. (*a*) Model the pendulum's motion as simple harmonic motion and find its speed as it passes through $\phi = 0$ by using the small angle approximation. (*b*) Using the conservation of energy, find this speed exactly for any angle (not just small angles). (*c*) Show that your result from Part (*b*) agrees

with the approximate answer in Part (*a*) when ϕ_0 is small. (*d*) Find the difference between the approximate and exact results for $\phi_0 = 0.20$ rad and $L = 1.0$ m.
(*e*) Find the difference between the approximate and exact results for $\phi_0 = 1.20$ rad and $L = 1.0$ m.

Picture the Problem The pictorial representation shows the simple pendulum at maximum angular displacement ϕ_0. We can express the angular position of the pendulum bob in terms of its initial angular position and time and differentiate this expression to find the maximum speed of the bob. We can use conservation of energy to find an exact value for v_{max} and the approximation $\cos\phi \approx 1 - \frac{1}{2}\phi^2$ to show that this value reduces to the former value for small ϕ.



(*a*) Relate the speed of the pendulum bob to its angular speed:

$$v = L\frac{d\phi}{dt} \qquad (1)$$

The angular position of the pendulum as a function of time is given by:

$$\phi = \phi_0 \cos\omega t$$

Differentiate this expression with respect to time to express the angular speed of the pendulum:

$$\frac{d\phi}{dt} = -\phi_0\omega \sin\omega t$$

Substitute in equation (1) to obtain:

$$v = -L\phi_0\omega \sin\omega t = -v_{max}\sin\omega t$$

Simplify v_{max} to obtain:

$$v_{max} = L\phi_0\sqrt{\frac{g}{L}} = \boxed{\phi_0\sqrt{gL}}$$

(*b*) Use conservation of energy to relate the potential energy of the pendulum at point 1 to its kinetic energy at point 2:

$$\Delta K + \Delta U = 0$$

or, because $K_1 = U_2 = 0$,

$$K_2 - U_1 = 0$$

Substitute for K_2 and U_1:

$$\tfrac{1}{2}mv_2^2 - mgh = 0$$

Express h in terms of L and ϕ_0: $h = L(1-\cos\phi_0)$

Substituting for h yields: $\frac{1}{2}mv_2^2 - mgL(1-\cos\phi_0) = 0$

Solve for $v_2 = v_{max}$ to obtain:

$$v_{max} = \boxed{\sqrt{2gL(1-\cos\phi_0)}} \qquad (2)$$

(c) For $\phi_0 << 1$: $1-\cos\phi_0 \approx \frac{1}{2}\phi_0^2$

Substitute in equation (2) to obtain:

$$v_{max} = \sqrt{2gL\left(\tfrac{1}{2}\phi_0^2\right)} = \boxed{\phi_0\sqrt{gL}}$$

in agreement with our result in Part (a).

(d) Express the difference in the results from (a) and (b): $\Delta v = v_{max,a} - v_{max,b}$

Substitute for $v_{max,a}$ and $v_{max,b}$ and simplify to obtain:

$$\begin{aligned}\Delta v &= \phi_0\sqrt{gL} - \sqrt{2gL(1-\cos\phi_0)} \\ &= \sqrt{gL}\left(\phi_0 - \sqrt{2(1-\cos\phi_0)}\right)\end{aligned} \qquad (3)$$

The ratio of Δv to v_{max} is given by:

$$\begin{aligned}\frac{\Delta v}{v_{max}} &= \frac{\sqrt{gL}\left(\phi_0 - \sqrt{2(1-\cos\phi_0)}\right)}{\phi_0\sqrt{gL}} \\ &= 1 - \frac{\sqrt{2(1-\cos\phi_0)}}{\phi_0}\end{aligned}$$

Substitute numerical values and evaluate Δv:

$$\Delta v = \sqrt{(9.81\ \text{m/s}^2)(1.0\ \text{m})}\left(0.20\ \text{rad} - \sqrt{2(1-\cos(0.20\ \text{rad}))}\right) \approx \boxed{1\ \text{mm/s}}$$

To make the importance of these Δv differences clearer, evaluate $\Delta v/v_{max}$ to obtain:

$$\begin{aligned}\frac{\Delta v}{v_{max}} &= 1 - \frac{\sqrt{2(1-\cos(0.20\ \text{rad}))}}{0.20\ \text{rad}} \\ &\approx 1.7\times10^{-3}\end{aligned}$$

(e) Evaluate equation (3) for $\phi_0 = 1.20$ rad and $L = 1.0$ m:

$$\Delta v = \sqrt{(9.81\ \text{m/s}^2)(1.0\ \text{m})}\left(1.20\ \text{rad} - \sqrt{2(1-\cos(1.20\ \text{rad}))}\right) \approx \boxed{0.2\ \text{m/s}}$$

Evaluating $\Delta v/v_{max}$ gives:

$$\begin{aligned}\frac{\Delta v}{v_{max}} &= 1 - \frac{\sqrt{2(1-\cos(1.20\ \text{rad}))}}{1.20\ \text{rad}} \\ &\approx 5.9\times10^{-2}\end{aligned}$$

Remarks: Note that the ratio of Δv to v_{max} is approximately 35 times larger for ϕ_0 = 0.20 rad than for ϕ_0 = 0.20 rad.

*Physical Pendulums

67 • **[SSM]** A thin 5.0-kg disk with a 20-cm radius is free to rotate about a fixed horizontal axis perpendicular to the disk and passing through its rim. The disk is displaced slightly from equilibrium and released. Find the period of the subsequent simple harmonic motion.

Picture the Problem The period of this physical pendulum is given by $T = 2\pi\sqrt{I/MgD}$ where I is the moment of inertia of the thin disk about the fixed horizontal axis passing through its rim. We can use the parallel-axis theorem to express I in terms of the moment of inertia of the disk about an axis through its center of mass and the distance from its center of mass to its pivot point.

Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}}$$

Using the parallel-axis theorem, find the moment of inertia of the thin disk about an axis through the pivot point:

$$I = I_{\mathrm{cm}} + MR^2 = \tfrac{1}{2}MR^2 + MR^2 = \tfrac{3}{2}MR^2$$

Substituting for I and simplifying yields:

$$T = 2\pi\sqrt{\frac{\tfrac{3}{2}MR^2}{MgR}} = 2\pi\sqrt{\frac{3R}{2g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{3(0.20\,\mathrm{m})}{2(9.81\,\mathrm{m/s^2})}} = \boxed{1.1\,\mathrm{s}}$$

68 • A circular hoop that has a 50-cm radius is hung on a narrow horizontal rod and allowed to swing in the plane of the hoop. What is the period of its oscillation, assuming that the amplitude is small?

Picture the Problem The period of this physical pendulum is given by $T = 2\pi\sqrt{I/MgD}$ where I is the moment of inertia of the circular hoop about an axis through its pivot point. We can use the parallel-axis theorem to express I in terms of the moment of inertia of the hoop about an axis through its center of mass and the distance from its center of mass to its pivot point.

Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}}$$

Using the parallel-axis theorem, find the moment of inertia of the circular hoop about an axis through the pivot point:

$$I = I_{\text{cm}} + MR^2 = MR^2 + MR^2 = 2MR^2$$

Substitute for I and simplify to obtain:

$$T = 2\pi\sqrt{\frac{2MR^2}{MgR}} = 2\pi\sqrt{\frac{2R}{g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{2(0.50\,\text{m})}{9.81\,\text{m/s}^2}} = \boxed{2.0\,\text{s}}$$

69 • A 3.0-kg plane figure is suspended at a point 10 cm from its center of mass. When it is oscillating with small amplitude, the period of oscillation is 2.6 s. Find the moment of inertia I about an axis perpendicular to the plane of the figure through the pivot point.

Picture the Problem The period of a physical pendulum is given by $T = 2\pi\sqrt{I/MgD}$ where I is its moment of inertia about an axis through its pivot point. We can solve this equation for I and evaluate it using the given numerical data.

Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}} \Rightarrow I = \frac{MgDT^2}{4\pi^2}$$

Substitute numerical values and evaluate I:

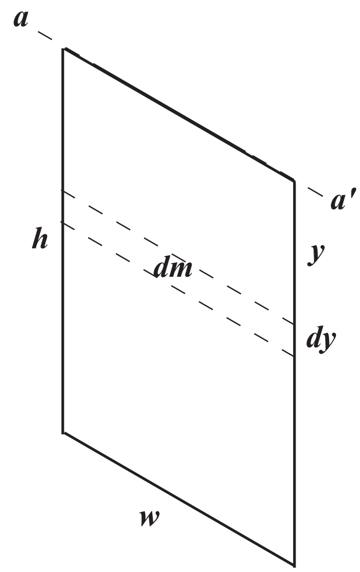
$$I = \frac{(3.0\,\text{kg})(9.81\,\text{m/s}^2)(0.10\,\text{m})(2.6\,\text{s})^2}{4\pi^2} = \boxed{0.50\,\text{kg}\cdot\text{m}^2}$$

70 •• You have designed a cat door that consists of a square piece of plywood that is 1.0 in. thick and 6.0 in. on a side, and is hinged at its top. To make sure the cat has enough time to get through it safely, the door should have a natural period of at least 1.0 s. Will your design work? If not, explain qualitatively what you would do to make it meet your requirements.

Picture the Problem The pictorial representation shows the cat door, of height h and width w, pivoted about an axis through a-a'. We can use

$$T = 2\pi\sqrt{\frac{I_{a-a'}}{mgD}}$$

to find the period of the door but first must find $I_{a-a'}$. The diagram also shows a differential strip of height dy and mass dm a distance y from the axis of rotation of the door. We can integrate the differential expression for the moment of inertia of this strip to determine the moment of inertia of the door.



The period of the cat door is given by:

$$T = 2\pi\sqrt{\frac{I_{a-a'}}{mgD}} \qquad (1)$$

where D is the distance from the center of mass of the door to the axis of rotation.

Express the moment of inertia, about the axis a-a', of the cat door:

$dI_{a-a'} = y^2 dm$

or, because $dm = \rho dV = \rho t dA = \rho w t dy$,

$dI_{a-a'} = \rho wt\, y^2 dy$

Integrating this expression between $y = 0$ and $y = h$ yields:

$$I_{a-a'} = \rho wt \int_0^h y^2 dy = \tfrac{1}{3}\rho wth^3$$

Because $\rho = \dfrac{m}{V} = \dfrac{m}{wht}$:

$$I_{a-a'} = \tfrac{1}{3}\left(\frac{m}{wht}\right)wth^3 = \tfrac{1}{3}mh^2$$

Substituting for D and $I_{a-a'}$ in equation (1) yields:

$$T = 2\pi\sqrt{\frac{\frac{1}{3}mh^2}{mg\left(\frac{1}{2}h\right)}} = 2\pi\sqrt{\frac{2h}{3g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{2\left(6.0\,\text{in}\times\dfrac{2.540\,\text{cm}}{\text{in}}\right)}{3\left(9.81\,\text{m/s}^2\right)}} = 0.64\,\text{s}$$

Thus the door's period is too short. The only way to increase it is to increase the height of the door.

71 •• You are given a meterstick and asked to drill a small diameter hole through it so that, when the stick is pivoted about a horizontal axis through the hole, the period of the pendulum will be a minimum. Where should you drill the hole?

Picture the Problem Let x be the distance of the pivot from the center of the meter stick, m the mass of the meter stick, and L its length. We'll express the period of the meter stick as a function of the distance x and then differentiate this expression with respect to x to determine where the hole should be drilled to minimize the period.

Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}} \qquad (1)$$

Express the moment of inertia of the meter stick about an axis through its center of mass:

$$I_{\text{cm}} = \tfrac{1}{12}mL^2$$

Using the parallel-axis theorem, express the moment of inertia of the meter stick about an axis through the pivot point:

$$I = I_{\text{cm}} + mx^2 = \tfrac{1}{12}mL^2 + mx^2$$

Substitute in equation (1) and simplify to obtain:

$$T = 2\pi\sqrt{\frac{\frac{1}{12}mL^2 + mx^2}{mgx}} = \frac{2\pi}{\sqrt{g}}\sqrt{\frac{L^2 + 12x^2}{12x}}$$

The condition for an extreme value of T is that $\dfrac{d}{dx}\left(\sqrt{\dfrac{L^2+12x^2}{12x}}\right) = 0.$

Evaluate this derivative to obtain:

$$\frac{12x^2 - L^2}{24x^2\sqrt{\dfrac{L^2+12x^2}{12x}}} = 0 \Rightarrow 12x^2 - L^2 = 0$$

Noting that only the positive solution is physically meaningful, solve for x:

$$x = \frac{L}{\sqrt{12}} = \frac{100\,\text{cm}}{\sqrt{12}} = 28.9\,\text{cm}$$

The hole should be drilled at a distance:

$$d = 50.0\,\text{cm} - 28.9\,\text{cm} = \boxed{21.1\,\text{cm}}$$

from the center of the meter stick.

72 •• Figure 14-29 shows a uniform disk that has a radius $R = 0.80$ m, a mass of 6.00 kg, and a small hole a distance d from the disk's center that can serve as a pivot point. (*a*) What should be the distance d so that the period of this physical pendulum is 2.50 s? (*b*) What should be the distance d so that this physical pendulum will have the shortest possible period? What is this shortest possible period?

Picture the Problem (*a*) Let m represent the mass and R the radius of the uniform disk. The disk is a physical pendulum. We'll use the expression $T = 2\pi\sqrt{I/mgd}$ for the period of a physical pendulum. To find I we use the parallel-axis theorem ($I = I_{\text{cm}} + md^2$). (*b*) The period is a minimum when $dT/dx = 0$, where, to avoid notational difficulties, we have substituted x for d.

(*a*) Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{mgd}}$$

Using the parallel-axis theorem ($I = I_{\text{cm}} + md^2$), relate the moment of inertia about the axis through the hole to the moment of inertia I_{cm} about the parallel axis through the center of mass. Obtain I_{cm} from Table 9-1:

$$I = I_{\text{cm}} + md^2 = \tfrac{1}{2}mR^2 + md^2$$

Substituting for I yields:

$$T = 2\pi\sqrt{\frac{\frac{1}{2}mR^2 + md^2}{mgd}} = 2\pi\sqrt{\frac{\frac{1}{2}R^2 + d^2}{gd}} \qquad (1)$$

Square both sides of this equation, simplify, and substitute numerical values to obtain:

$$d^2 - \frac{gT^2}{4\pi^2}d + \frac{R^2}{2} = 0$$

or

$$d^2 - (1.553\,\text{m})d + 0.320\,\text{m}^2 = 0$$

Use the quadratic formula or your graphing calculator to obtain:

$$d = 0.245\ \text{m} = \boxed{24\,\text{cm}}$$

The second root, $d = 1.31$ m, is greater than R, so it is too large to be physically meaningful.

(*b*) The period T is related to the distance d by equation (1). T will be a minimum when $\left(\frac{1}{2}R^2+d^2\right)/d$ is a minimum. Set the derivative of this expression equal to zero to find relative maxima and minima. We'll replace d with x to avoid the notational challenge of differentiating with respect to d. Evaluating $\frac{d}{dx}\left(\sqrt{\frac{\frac{1}{2}R^2+x^2}{x}}\right)=0$ yields:

$$\frac{2d^2-\left(\frac{1}{2}R^2+d^2\right)}{d^2}=0\Rightarrow 2d^2-\left(\frac{1}{2}R^2+d^2\right)=0$$

where we have changed x back to d.

Solving for d yields: $d=\boxed{\frac{R}{\sqrt{2}}}$

Evaluate equation (1) with $d=R/\sqrt{2}$ to obtain an expression for the shortest possible period:

$$T=2\pi\sqrt{\frac{\frac{1}{2}R^2+\frac{1}{2}R^2}{g\frac{R}{\sqrt{2}}}}=2\pi\sqrt{\frac{\sqrt{2}R}{g}}$$

Substitute numerical values and evaluate T:

$$T=2\pi\sqrt{\frac{\sqrt{2}(0.80\,\mathrm{m})}{9.81\,\mathrm{m/s^2}}}=\boxed{2.1\,\mathrm{s}}$$

Remarks: We've shown that $d=R/\sqrt{2}$ corresponds to an *extreme* value; that is, to a maximum, a minimum, or an inflection point. To verify that this value of d corresponds to a minimum, we can either (1) show that d^2T/dx^2 evaluated at $x=R/\sqrt{2}$ (where $x=d$) is positive, or (2) graph T as a function of d and note that the graph is a minimum at $d=R/\sqrt{2}$.

73 ••• [SSM] Points P_1 and P_2 on a plane object (Figure 14-30) are distances h_1 and h_2, respectively, from the center of mass. The object oscillates with the same period T when it is free to rotate about an axis through P_1 and when it is free to rotate about an axis through P_2. Both of these axes are perpendicular to the plane of the object. Show that $h_1+h_2=gT^2/(4\pi)^2$, where $h_1\neq h_2$.

Picture the Problem We can use the equation for the period of a physical pendulum and the parallel-axis theorem to show that $h_1+h_2=gT^2/4\pi^2$.

Express the period of the physical pendulum:

$$T=2\pi\sqrt{\frac{I}{mgd}}$$

Using the parallel-axis theorem, relate the moment of inertia about an axis through P_1 to the moment of inertia about an axis through the plane's center of mass:

$$I = I_{\text{cm}} + mh_1^2$$

Substitute for I to obtain:

$$T = 2\pi\sqrt{\frac{I_{\text{cm}} + mh_1^2}{mgh_1}}$$

Square both sides of this equation and rearrange terms to obtain:

$$\frac{mgT^2}{4\pi^2} = \frac{I_{\text{cm}}}{h_1} + mh_1 \qquad (1)$$

Because the period of oscillation is the same for point P_2:

$$\frac{I_{\text{cm}}}{h_1} + mh_1 = \frac{I_{\text{cm}}}{h_2} + mh_2$$

Combining like terms yields:

$$\left(\frac{1}{h_1} - \frac{1}{h_2}\right)I_{\text{cm}} = m(h_2 - h_1)$$

Provided $h_1 \neq h_2$:

$$I_{\text{cm}} = mh_1h_2$$

Substitute in equation (1) and simplify to obtain:

$$\frac{mgT^2}{4\pi^2} = \frac{mh_1h_2}{h_1} + mh_1$$

Solving for $h_1 + h_2$ gives:

$$h_1 + h_2 = \boxed{\frac{gT^2}{4\pi^2}}$$

74 ••• A physical pendulum consists of a spherical bob of radius r and mass m suspended from a rigid rod of negligible mass as in Figure 14-31. The distance from the center of the sphere to the point of support is L. When r is much less than L, such a pendulum is often treated as a simple pendulum of length L.
(*a*) Show that the period for small oscillations is given by $T = T_0\sqrt{1 + \frac{2r^2}{5L^2}}$ where $T_0 = 2\pi\sqrt{L/g}$ is the period of a simple pendulum of length L. (*b*) Show that when r is much smaller than L, the period can be approximated by $T \approx T_0\,(1 + r^2/5L^2)$. (*c*) If L = 1.00 m and r = 2.00 cm, find the error in the calculated value when the approximation $T = T_0$ is used for the period. How large must be the radius of the bob for the error to be 1.00 percent?

Picture the Problem (*a*) We can find the period of the physical pendulum in terms of the period of a simple pendulum by starting with $T = 2\pi\sqrt{I/mgL}$ and applying the parallel-axis theorem. (*b*) Performing a binomial expansion (with $r << L$) on the radicand of our expression for T will lead to $T \approx T_0(1 + r^2/5L^2)$.

(*a*) Express the period of the physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{mgL}}$$

Using the parallel-axis theorem, relate the moment of inertia of the pendulum about an axis through its center of mass to its moment of inertia about an axis through its point of support:

$$I = I_{\text{cm}} + mL^2 = \tfrac{2}{5}mr^2 + mL^2$$

Substitute for I and simplify to obtain:

$$T = 2\pi\sqrt{\frac{\frac{2}{5}mr^2 + mL^2}{mgL}} = 2\pi\sqrt{\frac{L}{g}}\sqrt{1+\frac{2r^2}{5L^2}} = \boxed{T_0\sqrt{1+\frac{2r^2}{5L^2}}}$$

(*b*) Expanding $\left(1+\frac{2r^2}{5L^2}\right)^{1/2}$ binomially yields:

$$\left(1+\frac{2r^2}{5L^2}\right)^{1/2} = 1+\frac{1}{2}\left(\frac{2r^2}{5L^2}\right)+\frac{1}{8}\left(\frac{2r^2}{5L^2}\right)^2 + \text{higher-order terms} \approx 1+\frac{r^2}{5L^2}$$

provided $r << L$

Substitute in our result from Part (*a*) to obtain:

$$T \approx \boxed{T_0\left(1+\frac{r^2}{5L^2}\right)}$$

(*c*) Express the fractional error when the approximation $T = T_0$ is used for this pendulum:

$$\frac{\Delta T}{T} \approx \frac{T - T_0}{T_0} = \frac{T}{T_0} - 1 = 1 + \frac{r^2}{5L^2} - 1 = \frac{r^2}{5L^2}$$

Substitute numerical values and evaluate $\Delta T/T$:

$$\frac{\Delta T}{T} \approx \frac{(2.00\,\text{cm})^2}{5(100\,\text{cm})^2} = \boxed{0.00800\%}$$

For an error of 1.00%:

$$\frac{r^2}{5L^2} = 0.0100 \Rightarrow r = L\sqrt{0.0500}$$

Substitute the numerical value of L and evaluate r to obtain:

$$r = (100\,\text{cm})\sqrt{0.0500} = \boxed{22.4\,\text{cm}}$$

75 ••• Figure 14-32 shows the pendulum of a clock in your grandmother's house. The uniform rod of length L = 2.00 m has a mass m = 0.800 kg. Attached to the rod is a uniform disk of mass M = 1.20 kg and radius 0.150 m. The clock is constructed to keep perfect time if the period of the pendulum is exactly 3.50 s. (*a*) What should the distance d be so that the period of this pendulum is 2.50 s? (*b*) Suppose that the pendulum clock loses 5.00 min/d. To make sure that your grandmother won't be late for her quilting parties, you decide to adjust the clock back to its proper period. How far and in what direction should you move the disk to ensure that the clock will keep perfect time?

Picture the Problem (*a*) The period of this physical pendulum is given by $T = 2\pi\sqrt{I/MgD}$. We can express its period as a function of the distance d by using the definition of the center of mass of the pendulum to find D in terms of d and the parallel-axis theorem to express I in terms of d. Solving the resulting quadratic equation yields d. (*b*) Because the clock is losing 5 minutes per day, one would reposition the disk so that the clock runs faster; that is, so the pendulum has a shorter period. We can determine the appropriate correction to make in the position of the disk by relating the fractional time loss to the fractional change in its position.

(*a*) Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{m_{\text{tot}}gx_{\text{cm}}}}$$

Solving for $\frac{I}{x_{\text{cm}}}$ yields:

$$\frac{I}{x_{\text{cm}}} = \frac{T^2 g m_{\text{tot}}}{4\pi^2} \qquad (1)$$

Express the moment of inertia of the physical pendulum, about an axis through the pivot point, as a function of d:

$$I = I_{\text{cm}} + Md^2 = \tfrac{1}{3}mL^2 + \tfrac{1}{2}Mr^2 + Md^2$$

Substitute numerical values and evaluate I:

$$\begin{aligned} I &= \tfrac{1}{3}(0.800\,\text{kg})(2.00\,\text{m})^2 \\ &\quad + \tfrac{1}{2}(1.20\,\text{kg})(0.150\,\text{m})^2 + (1.20\,\text{kg})d^2 \\ &= 1.0802\,\text{kg}\cdot\text{m}^2 + (1.20\,\text{kg})d^2 \end{aligned}$$

Locate the center of mass of the physical pendulum relative to the pivot point:

$$x_{cm} = \frac{(0.800\,\text{kg})(1.00\,\text{m}) + (1.20\,\text{kg})d}{2.00\,\text{kg}}$$

and

$$\boldsymbol{x}_{cm} = 0.400\,\text{m} + 0.600\boldsymbol{d}$$

Substitute in equation (1) to obtain:

$$\frac{1.0802\,\text{kg}\cdot\text{m}^2 + (1.20\,\text{kg})d^2}{0.400\,\text{m} + 0.600d} = \frac{T^2(9.81\,\text{m/s}^2)(2.00\,\text{kg})}{4\pi^2} = (0.49698\,\text{kg}\cdot\text{m/s}^2)T^2 \quad (2)$$

Setting $T = 2.50$ s and solving for d yields:

$$d = 1.63574\,\text{m} = \boxed{1.64\,\text{m}}$$

(b) There are 1440 minutes per day. If the clock loses 5.00 min per day, then the period of the clock is related to the perfect period of the clock by:

$$1435T = 1440T_{perfect} \Rightarrow T = \frac{1440}{1435}T_{perfect}$$

where $T_{perfect} = 3.50$ s.

Substitute numerical values and evaluate T:

$$T = \frac{1440}{1435}(3.50\,\text{s}) = 3.51220\,\text{s}$$

Substitute $T = 3.51220$ s in equation (2) and solve for d to obtain:

$$d = 3.40140\,\text{m}$$

Substitute $T = 3.50$ s in equation (2) and solve for d' to obtain:

$$d' = 3.37826\,\text{m}$$

Express the distance the disk needs to be moved upward to correct the period:

$$\Delta d = d - d' = 3.40140\,\text{m} - 3.37826\,\text{m} = \boxed{2.31\,\text{cm}}$$

Damped Oscillations

76 • A 2.00-kg object oscillates with an initial amplitude of 3.00 cm. The force constant of the spring is 400 N/m. Find (a) the period, and (b) the total initial energy. (c) If the energy decreases by 1.00 percent per period, find the linear damping constant b and the Q factor.

Picture the Problem (a) We can find the period of the oscillator from $T = 2\pi\sqrt{m/k}$. (b) The total initial energy of the spring-object system is given by $E_0 = \frac{1}{2}kA^2$. (c) The Q factor can be found from its definition $Q = 2\pi/\left(|\Delta E|/E\right)_{\text{cycle}}$ and the damping constant from $Q = \omega_0 m/b$.

(a) The period of the oscillator is given by:

$$T = 2\pi\sqrt{\frac{m}{k}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{2.00\,\text{kg}}{400\,\text{N/m}}} = \boxed{0.444\,\text{s}}$$

(b) Relate the initial energy of the oscillator to its amplitude:

$$E_0 = \tfrac{1}{2}kA^2$$

Substitute numerical values and evaluate E_0:

$$E_0 = \tfrac{1}{2}(400\,\text{N/m})(0.0300\,\text{m})^2 = \boxed{0.180\,\text{J}}$$

(c) Relate the fractional rate at which the energy decreases to the Q value and evaluate Q:

$$Q = \frac{2\pi}{\left(|\Delta E|/E\right)_{\text{cycle}}} = \frac{2\pi}{0.0100} = \boxed{628}$$

Express the Q value in terms of b:

$$Q = \frac{\omega_0 m}{b}$$

Solve for the damping constant b:

$$b = \frac{\omega_0 m}{Q} = \frac{2\pi m}{TQ} = \frac{2\pi m}{2\pi\sqrt{\frac{m}{k}}Q} = \frac{\sqrt{mk}}{Q}$$

Substitute numerical values and evaluate b:

$$b = \frac{\sqrt{(2.00\,\text{kg})(400\,\text{N/m})}}{628} = \boxed{0.0450\,\text{kg/s}}$$

77 •• [SSM] Show that the ratio of the amplitudes for two successive oscillations is constant for a linearly damped oscillator.

Picture the Problem The amplitude of the oscillation at time t is $A(t) = A_0 e^{-t/2\tau}$ where $\tau = m/b$ is the decay constant. We can express the amplitudes one period apart and then show that their ratio is constant.

Relate the amplitude of a given oscillation peak to the time at which the peak occurs:

$$A(t) = A_0 e^{-t/2\tau}$$

Express the amplitude of the oscillation peak at $t' = t + T$:

$$A(t+T) = A_0 e^{-(t+T)/2\tau}$$

Express the ratio of these consecutive peaks:

$$\frac{A(t)}{A(t+T)} = \frac{A_0 e^{-t/2\tau}}{A_0 e^{-(t+T)/2\tau}} = e^{-T/2\tau} = \boxed{\text{constant}}$$

78 •• An oscillator has a period of 3.00 s. Its amplitude decreases by 5.00 percent during each cycle. (*a*) By how much does its mechanical energy decrease during each cycle? (*b*) What is the time constant τ? (*c*) What is the *Q* factor?

Picture the Problem (*a*) We can relate the fractional change in the energy of the oscillator each cycle to the fractional change in its amplitude. (*b*) and (*c*) Both the *Q* value and the decay constant τ can be found from their definitions.

(*a*) Relate the energy of the oscillator to its amplitude:

$$E = \tfrac{1}{2}kA^2$$

Take the differential of this relationship to obtain:

$$dE = kAdA$$

Divide the second of these equations by the first and simplify to obtain:

$$\frac{dE}{E} = \frac{kAdA}{\frac{1}{2}kA^2} = 2\frac{dA}{A}$$

Approximate dE and dA by ΔE and ΔA and evaluate $\Delta E/E$:

$$\frac{\Delta E}{E} = 2(5.00\%) = \boxed{10.0\%}$$

(*b*) For small damping:

$$\frac{|\Delta E|}{E} = \frac{T}{\tau}$$

and

$$\tau = \frac{T}{|\Delta E|/E} = \frac{3.00\,\text{s}}{0.100} = \boxed{30.0\,\text{s}}$$

(*c*) The *Q* factor is given by:

$$Q = \omega_0\tau = \left(\frac{2\pi}{T}\right)\tau$$

Substitute numerical values and evaluate Q:

$$Q = \frac{2\pi}{3.00\,\text{s}}(30.0\,\text{s}) = \boxed{62.8}$$

79 •• A linearly damped oscillator has a Q factor of 20. (a) By what fraction does the energy decrease during each cycle? (b) Use Equation 14-40 to find the percentage difference between ω' and ω_0. *Hint: Use the approximation* $(1+x)^{1/2} \approx 1 + \frac{1}{2}x$ *for small x.*

Picture the Problem We can use the physical interpretation of Q for small damping $\left(Q = \dfrac{2\pi}{\left(|\Delta E|/E\right)_{\text{cycle}}}\right)$ to find the fractional decrease in the energy of the oscillator each cycle.

(a) Express the fractional decrease in energy each cycle as a function of the Q factor and evaluate $|\Delta E|/E$:

$$\frac{|\Delta E|}{E} = \frac{2\pi}{Q} = \frac{2\pi}{20} = 0.314 = \boxed{0.31}$$

(b) The percentage difference between ω' and ω_0 is given by:

$$\frac{\omega' - \omega_0}{\omega_0} = \frac{\omega'}{\omega_0} - 1$$

Using the definition of the Q factor, use Equation 14-40 to express the ratio of ω' to ω_0 as a function of Q:

$$\frac{\omega'}{\omega_0} = \left[1 - \frac{1}{4}\left(\frac{b^2}{m^2\omega_0^2}\right)\right]^{1/2} = \left[1 - \frac{1}{4Q^2}\right]^{1/2}$$

Substituting for $\dfrac{\omega'}{\omega_0}$ yields:

$$\frac{\omega' - \omega_0}{\omega_0} = \left[1 - \frac{1}{4Q^2}\right]^{1/2} - 1$$

Use the approximation

$$(1+x)^{1/2} \approx 1 + \tfrac{1}{2}x$$

for $x << 1$ to obtain:

$$\left[1 - \frac{1}{4Q^2}\right]^{1/2} \approx 1 - \frac{1}{8Q^2}$$

Substituting for $\left[1 - \dfrac{1}{4Q^2}\right]^{1/2}$ and simplifying yields:

$$\frac{\omega' - \omega_0}{\omega_0} = 1 - \frac{1}{8Q^2} - 1 = -\frac{1}{8Q^2}$$

Substitute the numerical value of Q and evaluate $\dfrac{\omega' - \omega_0}{\omega_0}$:

$$\frac{\omega' - \omega_0}{\omega_0} = -\frac{1}{8(20)^2} = \boxed{-3.1\times10^{-2}\%}$$

80 •• A linearly damped mass–spring system oscillates at 200 Hz. The time constant of the system is 2.0 s. At $t = 0$ the amplitude of oscillation is 6.0 cm and the energy of the oscillating system is 60 J. (*a*) What are the amplitudes of oscillation at t = 2.0 s and t = 4.0 s? (*b*) How much energy is dissipated in the first 2-s interval and in the second 2-s interval?

Picture the Problem The energy of the spring-and-mass oscillator varies with time according to $E = E_0 e^{-t/\tau}$ and its energy is proportional to the square of the amplitude.

(*a*) Using $E = E_0 e^{-t/\tau}$ and $E \propto A^2$, solve for the amplitude A as a function of time:

$E = E_0 e^{-t/\tau}$ and $E \propto A^2$ imply that $A^2 = A_0^2 e^{-t/\tau}$

Hence $A = A_0 e^{-t/2\tau}$

Express the amplitude of the oscillations as a function of time:

$$A = (6.0\text{ cm})e^{-t/4\text{ s}}$$

Evaluate the amplitude when t = 2.0 s:

$$A(2.0\text{ s}) = (6.0\text{ cm})e^{-2.0\text{ s}/4.0\text{ s}} = \boxed{3.6\text{ cm}}$$

Evaluate the amplitude when t = 4.0 s:

$$A(4.0\text{ s}) = (6.0\text{ cm})e^{-4.0\text{ s}/4.0\text{ s}} = \boxed{2.2\text{ cm}}$$

(*b*) Express the energy of the system at t = 0, t = 2.0 s, and t = 4.0 s:

$$E(0) = E_0 e^{-0/2.0\text{s}} = E_0$$
$$E(2.0\text{ s}) = E_0 e^{-2.0/2.0\text{s}} = E_0 e^{-1}$$
$$E(4.0\text{ s}) = E_0 e^{-4.0/2.0\text{s}} = E_0 e^{-2}$$

The energy dissipated in the first 2.0 s is equal to the negative of the change in mechanical energy:

$$-\Delta E_{0\to 2.0\text{ s}} = -E_0\left(e^{-2.0\text{ s}/2.0\text{ s}} - e^0\right) = (60\text{ J})\left(1 - e^{-1}\right) = \boxed{38\text{ J}}$$

The energy dissipated in the second 2.0-s interval is:

$$-\Delta E_{2.0\text{ s}\to 4.0\text{ s}} = -E_0\left(e^{-4.0\text{ s}/2.0\text{ s}} - e^{-2.0\text{ s}/2.0\text{ s}}\right) = (60\text{ J})e^{-1}\left(1 - e^{-1}\right) = \boxed{14\text{ J}}$$

81 •• **[SSM]** Seismologists and geophysicists have determined that the vibrating Earth has a resonance period of 54 min and a Q factor of about 400. After a large earthquake, Earth will "ring" (continue to vibrate) for up to 2 months. (*a*) Find the percentage of the energy of vibration lost to damping forces during each cycle. (*b*) Show that after n periods the vibrational energy is given by $E_n = (0.984)^n E_0$, where E_0 is the original energy. (*c*) If the original energy of vibration of an earthquake is E_0, what is the energy after 2.0 d?

Picture the Problem (*a*) We can find the fractional loss of energy per cycle from the physical interpretation of Q for small damping. (*b*) We will also find a general expression for Earth's vibrational energy as a function of the number of cycles it has completed. (*c*) We can then solve this equation for Earth's vibrational energy after any number of days.

(*a*) Express the fractional change in energy as a function of Q:

$$\frac{\Delta E}{E}=\frac{2\pi}{Q}=\frac{2\pi}{400}=\boxed{1.57\%}$$

(*b*) Express the energy of the damped oscillator after one cycle:

$$E_1=E_0\left(1-\frac{\Delta E}{E}\right)$$

Express the energy after two cycles:

$$E_2=E_1\left(1-\frac{\Delta E}{E}\right)=E_0\left(1-\frac{\Delta E}{E}\right)^2$$

Generalizing to n cycles:

$$E_n=E_0\left(1-\frac{\Delta E}{E}\right)^n=E_0(1-0.0157)^n$$
$$=\boxed{E_0(0.984)^n}$$

(*c*) Express 2.0 d in terms of the number of cycles; that is, the number of vibrations Earth will have experienced:

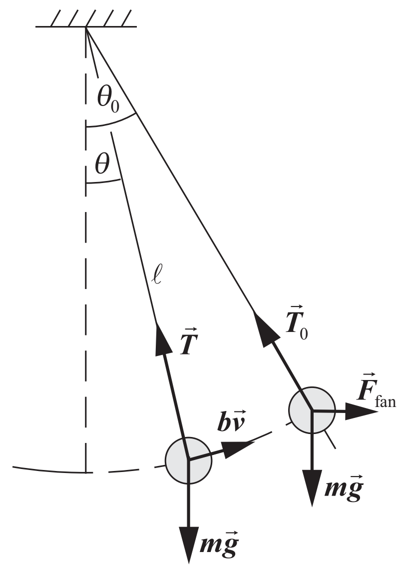
$$2.0\,\text{d}=2.0\,\text{d}\times\frac{24\,\text{h}}{\text{d}}\times\frac{60\,\text{m}}{\text{h}}$$
$$=2880\,\text{min}\times\frac{1T}{54\,\text{min}}$$
$$=53.3T$$

Evaluate E(2 d):

$$E(2\,\text{d})=E_0(0.9843)^{53.3}=\boxed{0.43E_0}$$

82 ••• A pendulum that is used in your physics laboratory experiment has a length of 75 cm and a compact bob with a mass equal to 15 g. To start the bob oscillating, you place a fan next to it that blows a horizontal stream of air on the bob. With the fan on, the bob is in equilibrium when the pendulum is displaced by an angle of 5.0º from the vertical. The speed of the air from the fan is 7.0 m/s. You turn the fan off, and allow the pendulum to oscillate. (*a*) Assuming that the drag force due to the air is of the form $-bv$, predict the decay time constant τ for this pendulum. (*b*) How long will it take for the pendulum's amplitude to reach 1.0º?

Picture the Problem The diagram shows 1) the pendulum bob displaced through an angle θ_0 and held in equilibrium by the force exerted on it by the air from the fan and 2) the bob accelerating, under the influence of gravity, tension force, and drag force, toward its equilibrium position. We can apply Newton's second law to the bob to obtain the equation of motion of the damped pendulum and then use its solution to find the decay time constant and the time required for the amplitude of oscillation to decay to 1°.



(*a*) Apply $\sum \tau = I\alpha$ to the pendulum to obtain:

$$-mg\ell\sin\theta + \ell F_{\text{d}} = I\frac{d^2\theta}{dt^2}$$

Express the moment of inertia of the pendulum about an axis through its point of support:

$$I = m\ell^2$$

Substitute for I and F_{d} to obtain:

$$m\ell^2\frac{d^2\theta}{dt^2} + \ell bv + mg\ell\sin\theta = 0$$

Because $\theta << 1$ and $v = \ell\omega = \ell d\theta/dt$:

$$m\ell^2\frac{d^2\theta}{dt^2} + \ell^2 b\frac{d\theta}{dt} + mg\ell\theta \approx 0$$

or

$$m\frac{d^2\theta}{dt^2} + b\frac{d\theta}{dt} + \frac{mg}{\ell}\theta \approx 0$$

The solution to this second-order homogeneous differential equation with constant coefficients is:

$$\theta = \theta_0 e^{-t/2\tau}\cos(\omega' t + \delta) \qquad (1)$$

where θ_0 is the maximum amplitude, $\tau = m/b$ is the time constant, and the frequency $\omega' = \omega_0\sqrt{1-(b/2m\omega_0)^2}$.

Apply $\sum \vec{F} = m\vec{a}$ to the bob when it is at its maximum angular displacement to obtain:

$$\sum F_x = F_{\text{fan}} - T\sin\theta_0 = 0$$

and

$$\sum F_y = T\cos\theta_0 - mg = 0$$

Divide the x-direction equation by the y-direction equation to obtain:

$$\frac{F_{\text{fan}}}{mg} = \frac{T\sin\theta_0}{T\cos\theta_0} = \tan\theta_0$$

or

$$F_{\text{fan}} = mg\tan\theta_0$$

When the bob is in equilibrium, the drag force on it equals F_{fan}:

$$bv = mg\tan\theta_0 \Rightarrow \tau = \frac{m}{b} = \frac{v}{g\tan\theta_0}$$

Substitute numerical values and evaluate τ:

$$\tau = \frac{7.0\,\text{m/s}}{\left(9.81\,\text{m/s}^2\right)\tan 5.0°} = 8.16\,\text{s} = \boxed{8.2\,\text{s}}$$

(b) From equation (1), the angular amplitude of the motion is given by:

$$\theta = \theta_0 e^{-t/2\tau}$$

When the amplitude has decreased to 1.0°:

$$1.0° = 5.0° e^{-t/2\tau} \text{ or } e^{-t/2\tau} = 0.20$$

Take the natural logarithm of both sides of the equation to obtain:

$$-\frac{t}{2\tau} = \ln(0.20) \Rightarrow t = -2\tau\ln(0.20)$$

Substitute the numerical value of τ and evaluate t:

$$t = -2(8.16\,\text{s})\ln(0.20) = \boxed{26\text{ s}}$$

83 ••• [SSM] You are in charge of monitoring the viscosity of oils at a manufacturing plant and you determine the viscosity of an oil by using the following method: The viscosity of a fluid can be measured by determining the decay time of oscillations for an oscillator that has known properties and operates while immersed in the fluid. As long as the speed of the oscillator through the fluid is relatively small, so that turbulence is not a factor, the drag force of the fluid on a sphere is proportional to the sphere's speed relative to the fluid: $F_\text{d} = 6\pi a\eta v$, where η is the viscosity of the fluid and a is the sphere's radius. Thus, the constant b is given by $6\pi a\eta$. Suppose your apparatus consists of a stiff spring that has a force constant equal to 350 N/cm and a gold sphere (radius 6.00 cm) hanging on the spring. (a) What viscosity of an oil do you measure if the decay time for this system is 2.80 s? (b) What is the Q factor for your system?

Picture the Problem (a) The decay time for a damped oscillator (with speed-dependent damping) system is defined as the ratio of the mass of the oscillator to the coefficient of v in the damping force expression. (b) The Q factor is the product of the resonance frequency and the damping time.

(a) From $F_\text{d} = 6\pi a\eta v$ and $F_\text{d} = -bv$, it follows that:

$$b = 6\pi a\eta \Rightarrow \eta = \frac{b}{6\pi a}$$

Because $\tau = m/b$, we can substitute for b to obtain:

$$\eta = \frac{m}{6\pi a \tau}$$

Substituting $m = \rho V$ and simplifying yields:

$$\eta = \frac{\rho V}{6\pi a \tau} = \frac{\frac{4}{3}\pi a^3 \rho}{6\pi a \tau} = \frac{2a^2 \rho}{9\tau}$$

Substitute numerical values and evaluate η (see Table 13-1 for the density of gold):

$$\eta = \frac{2(0.0600\ \text{m})^2\left(19.3\times10^3\ \text{kg/m}^3\right)}{9(2.8\ \text{s})} = \boxed{5.51\ \text{Pa}\cdot\text{s}}$$

(*b*) The Q factor is the product of the resonance frequency and the damping time:

$$Q = \omega_0\tau = \sqrt{\frac{k}{m}}\tau = \sqrt{\frac{k}{\rho V}}\tau = \sqrt{\frac{k}{\frac{4}{3}\pi a^3 \rho}}\tau$$

Substitute numerical values and evaluate Q:

$$Q = \sqrt{\frac{3\left(350\,\frac{\text{N}}{\text{cm}}\times\frac{100\ \text{cm}}{\text{m}}\right)}{4\pi(0.0600\ \text{m})^3\left(19.3\times10^3\ \text{kg/m}^3\right)}}(2.80\ \text{s}) \approx \boxed{125}$$

Driven Oscillations and Resonance

84 • A linearly damped oscillator loses 2.00 percent of its energy during each cycle. (*a*) What is its Q factor? (*b*) If its resonance frequency is 300 Hz, what is the width of the resonance curve $\Delta\omega$ when the oscillator is driven?

Picture the Problem (*a*) We can use the physical interpretation of Q for small damping to find the Q factor for this damped oscillator. (*b*) The width of the resonance curve depends on the Q factor according to $\Delta\omega = \omega_0/Q$.

(*a*) Using the physical interpretation of Q for small damping, relate Q to the fractional loss of energy of the damped oscillator per cycle:

$$Q = \frac{2\pi}{\left(|\Delta E|/E\right)_{\text{cycle}}}$$

Evaluate this expression for $\left(|\Delta E|/E\right)_{\text{cycle}} = 2.00\%$:

$$Q = \frac{2\pi}{0.0200} = \boxed{314}$$

(*b*) Relate the width of the resonance curve to the Q value of the oscillatory system:

$$\Delta\omega = \frac{\omega_0}{Q} = \frac{2\pi f_0}{Q}$$

Substitute numerical values and evaluate $\Delta\omega$:

$$\Delta\omega = \frac{2\pi\left(300\,\text{s}^{-1}\right)}{314} = \boxed{6.00\,\text{rad/s}}$$

85 • Find the resonance frequency for each of the three systems shown in Figure 14-33.

Picture the Problem The resonant frequency of a vibrating system depends on the mass m of the system and on its "stiffness" constant k according to $f_0 = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$ or, in the case of a simple pendulum oscillating with small-amplitude vibrations, $f_0 = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$.

(*a*) For this spring-and-mass oscillator we have:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{400.0\,\text{N/m}}{10\,\text{kg}}} = \boxed{1.0\,\text{Hz}}$$

(*b*) For this spring-and-mass oscillator we have:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{800.0\,\text{N/m}}{5\,\text{kg}}} = \boxed{2\,\text{Hz}}$$

(*c*) For this simple pendulum we have:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{9.81\,\text{m/s}^2}{2.0\,\text{m}}} = \boxed{0.35\,\text{Hz}}$$

86 •• A damped oscillator loses 3.50 percent of its energy during each cycle. (*a*) How many cycles elapse before half of its original energy is dissipated? (*b*) What is its Q factor? (*c*) If the natural frequency is 100 Hz, what is the width of the resonance curve when the oscillator is driven by a sinusoidal force?

Picture the Problem (*a*) We'll find a general expression for the damped oscillator's energy as a function of the number of cycles it has completed. We can then solve this equation for the number of cycles corresponding to the loss of half the oscillator's energy. (*b*) The Q factor is related to the fractional energy loss per cycle through $\Delta E/E = 2\pi/Q$. (*c*) The width of the resonance curve is $\Delta\omega = \omega_0/Q$ where ω_0 is the oscillator's natural angular frequency.

(*a*) Express the energy of the damped oscillator after one cycle:

$$E_1 = E_0\left(1 - \frac{\Delta E}{E}\right)$$

Express the energy after two cycles:

$$E_2 = E_1\left(1 - \frac{\Delta E}{E}\right) = E_0\left(1 - \frac{\Delta E}{E}\right)^2$$

Generalizing to n cycles:

$$E_n = E_0\left(1-\frac{\Delta E}{E}\right)^n$$

Substituting numerical values yields:

$$0.50E_0 = E_0(1-0.035)^n$$

or

$$0.50 = (0.965)^n$$

Solving for n yields:

$$n = \frac{\ln 0.50}{\ln 0.965} = 19.46$$

$$\approx \boxed{19\text{ complete cycles.}}$$

(b) Apply the physical interpretation of Q for small damping to obtain:

$$Q = \frac{2\pi}{\Delta E/E} = \frac{2\pi}{0.0350} = \boxed{180}$$

(c) The width of the resonance curve is given by:

$$\Delta\omega = \frac{\omega_0}{Q} = \frac{2\pi f_0(\Delta E/E)}{2\pi} = f_0(\Delta E/E)$$

Substitute numerical values and evaluate $\Delta\omega$:

$$\Delta\omega = (100\text{ Hz})(0.0350) = \boxed{3.50\text{ rad/s}}$$

87 •• [SSM] A 2.00-kg object oscillates on a spring of force constant 400 N/m. The linear damping constant has a value of 2.00 kg/s. The system is driven by a sinusoidal force of maximum value 10.0 N and angular frequency 10.0 rad/s. (a) What is the amplitude of the oscillations? (b) If the driving frequency is varied, at what frequency will resonance occur? (c) What is the amplitude of oscillation at resonance? (d) What is the width of the resonance curve $\Delta\omega$?

Picture the Problem (a) The amplitude of the damped oscillations is related to the damping constant, mass of the system, the amplitude of the driving force, and the natural and driving frequencies through $A = \dfrac{F_0}{\sqrt{m^2\left(\omega_0^2-\omega^2\right)^2+b^2\omega^2}}$. ($b$) Resonance occurs when $\omega = \omega_0$. (c) At resonance, the amplitude of the oscillations is $A = F_0\big/\sqrt{b^2\omega^2}$. ($d$) The width of the resonance curve is related to the damping constant and the mass of the system according to $\Delta\omega = b/m$.

(a) Express the amplitude of the oscillations as a function of the driving frequency:

$$A = \frac{F_0}{\sqrt{m^2\left(\omega_0^2-\omega^2\right)^2+b^2\omega^2}}$$

Because $\omega_0 = \sqrt{\dfrac{k}{m}}$:

$$A = \frac{F_0}{\sqrt{m^2\left(\dfrac{k}{m} - \omega^2\right)^2 + b^2\omega^2}}$$

Substitute numerical values and evaluate A:

$$A = \frac{10.0\ \text{N}}{\sqrt{(2.00\ \text{kg})^2\left(\dfrac{400\ \text{N/m}}{2.00\ \text{kg}} - (10.0\ \text{rad/s})^2\right)^2 + (2.00\ \text{kg/s})^2(10.0\ \text{rad/s})^2}} = \boxed{4.98\ \text{cm}}$$

(*b*) Resonance occurs when:

$$\omega = \omega_0 = \sqrt{\frac{k}{m}}$$

Substitute numerical values and evaluate ω:

$$\omega = \sqrt{\frac{400\ \text{N/m}}{2.00\ \text{kg}}} = 14.14\ \text{rad/s}$$
$$= \boxed{14.1\ \text{rad/s}}$$

(*c*) The amplitude of the motion at resonance is given by:

$$A = \frac{F_0}{\sqrt{b^2\omega_0^2}} = \frac{F_0}{b\omega_0}$$

Substitute numerical values and evaluate A:

$$A = \frac{10.0\ \text{N}}{(2.00\ \text{kg/s})(14.14\ \text{rad/s})}$$
$$= \boxed{35.4\ \text{cm}}$$

(*d*) The width of the resonance curve is:

$$\Delta\omega = \frac{b}{m} = \frac{2.00\ \text{kg/s}}{2.00\ \text{kg}} = \boxed{1.00\ \text{rad/s}}$$

88 •• Suppose you have the same apparatus described in Problem 83 and the same gold sphere hanging from a weaker spring that has a force constant of only 35.0 N/cm. You have studied the viscosity of ethylene glycol with this device, and found that ethylene glycol has a viscosity value of 19.9 mPa·s. Now you decide to drive this system with an external oscillating force. (*a*) If the magnitude of the driving force for the device is 0.110 N and the device is driven at resonance, how large would be the amplitude of the resulting oscillation? (*b*) If the system were not driven, but were allowed to oscillate, what percentage of its energy would it lose per cycle?

Picture the Problem (*a*) The amplitude of the steady-state oscillations when the system is in resonance is given by $A = F_0/b\omega$. (*b*) We can relate the fractional energy loss to the Q value of the oscillator.

(*a*) The amplitude of the steady-state oscillations when the system is in resonance is given by:

$$A = \frac{F_0}{b\omega}$$

Because $b = 6\pi a\eta$, and $\omega = \sqrt{k/m}$:

$$A = \frac{F_0}{6\pi a\eta\omega} = \frac{F_0}{6\pi a\eta}\sqrt{\frac{m}{k}}$$

Substituting $m = \rho V$ and simplifying yields:

$$A = \frac{F_0}{6\pi a\eta}\sqrt{\frac{\rho V}{k}} = \frac{F_0}{6\pi a\eta}\sqrt{\frac{\frac{4}{3}\pi a^3\rho}{k}} = \frac{F_0}{3\pi\eta}\sqrt{\frac{\pi a\rho}{3k}}$$

Substitute numerical values and evaluate A:

$$A = \frac{0.110\text{ N}}{3\pi(19.9\text{ mPa}\cdot\text{s})}\sqrt{\frac{\pi(0.0600\text{ m})(19.3\times10^3\text{ kg/m}^3)}{3(35.0\text{ N/cm})}} = \boxed{34.5\text{ cm}}$$

(*b*) This is a very weakly damped system and so we can relate the fractional energy loss per cycle to the system's Q value:

$$Q = \frac{2\pi}{(\Delta E/E)_{\text{cycle}}} = \omega_0\tau$$

Because $\tau = \dfrac{m}{b} = \dfrac{m}{6\pi a\eta}$:

$$\frac{2\pi}{(\Delta E/E)_{\text{cycle}}} = \frac{m\omega_0}{6\pi a\eta}$$

Substituting for m and ω_0 and simplifying yields:

$$\frac{2\pi}{(\Delta E/E)_{\text{cycle}}} = \frac{\rho V\sqrt{\frac{k}{m}}}{6\pi a\eta} = \frac{\frac{4}{3}\pi a^3\rho}{6\pi a\eta}\sqrt{\frac{k}{m}} = \frac{2a^2\rho}{9\eta}\sqrt{\frac{k}{m}}$$

Solve for $(\Delta E/E)_{\text{cycle}}$ to obtain:

$$(\Delta E/E)_{\text{cycle}} = \frac{9\pi\eta}{a^2\rho}\sqrt{\frac{m}{k}}$$

Substituting for m and then for V and simplifying gives:

$$(\Delta E/E)_{\text{cycle}} = \frac{9\pi\eta}{a^2\rho}\sqrt{\frac{\rho V}{k}} = \frac{9\pi\eta}{a^2\rho}\sqrt{\frac{\rho\frac{4}{3}\pi a^3}{k}} = 18\pi\eta\sqrt{\frac{\pi}{3a\rho k}}$$

Substitute numerical values and evaluate $(\Delta E/E)_{\text{cycle}}$:

$$(\Delta E/E)_{\text{cycle}} = 18\pi(19.9\text{ mPa}\cdot\text{s})\sqrt{\frac{\pi}{3(6.00\text{ cm})(19.3\times10^3\text{ kg/m}^3)(350\text{ N/cm})}} = \boxed{1.81\times10^{-4}}$$

General Problems

89 • A particle's displacement from equilibrium is given by $x(t) = 0.40\cos(3.0t + \pi/4)$, where x is in meters and t is in seconds. (a) Find the frequency and period of its motion. (b) Find an expression for the velocity of the particle as a function of time. (c) What is its maximum speed?

Picture the Problem (a) The particle's displacement from equilibrium is $x = A\cos(\omega t + \delta)$. Thus, we have $A = 0.40$ m, $\omega = 3.0$ rad/s, and $\delta = \pi/4$. We can find the frequency of the motion from its angular frequency and the period from the frequency. (b) The particle's velocity is the time derivative of its displacement. (c) The particle's maximum speed occurs when $\sin(\omega t + \delta) = -1$.

(a) The particle's displacement from equilibrium is of the form
$$x = A\cos(\omega t + \delta).$$
Comparing this to the given equation we see that:

$\omega = 3.0\text{ rad/s}$
and so
$$f = \frac{\omega}{2\pi} = \frac{3.0\text{ rad/s}}{2\pi} = 0.477\text{ Hz} = \boxed{0.48\text{ Hz}}$$

The period of the particle's motion is the reciprocal of its frequency:

$$T = \frac{1}{f} = \frac{1}{0.477\text{ s}^{-1}} = 2.09\text{ s} = \boxed{2.1\text{ s}}$$

(b) Differentiate $x = A\cos(\omega t + \delta)$ with respect to time to obtain an expression for the particle's velocity:

$$v_x = \frac{dx}{dt} = \frac{d}{dt}[A\cos(\omega t + \delta)] = -\omega A\sin(\omega t + \delta)$$

Substituting for A, ω, and δ yields:

$$v_x = -(3.0\text{ rad/s})(0.40\text{ m})\sin\left[(3.0\text{ rad/s})t + \frac{\pi}{4}\right] = \boxed{-(1.2\text{ m/s})\sin\left[(3.0\text{ rad/s})t + \frac{\pi}{4}\right]}$$

(*c*) The particle's maximum speed occurs when $\sin(\omega t + \delta) = \pm 1$:

$$|v_{x\,\max}| = |-(1.2\text{ m/s})(\pm 1)| = \boxed{1.2\text{ m/s}}$$

90 • An astronaut arrives at a new planet, and gets out his simple device to determine the gravitational acceleration there. Prior to his arrival, he noted that the radius of the planet was 7550 km. If his 0.500-m-long pendulum has a period of 1.0 s, what is the mass of the planet?

Picture the Problem We can apply Newton's second law and the law of gravity to an object at the surface of the new planet to obtain an expression for the mass of the planet as a function of the acceleration due to gravity at its surface. We can use the period of the astronaut's pendulum to obtain an expression for the acceleration of gravity a_g at the surface of the new planet.

Apply Newton's second law and the law of gravity to an object of mass m at the surface of the planet:

$$\frac{GM_{\text{planet}}m}{R_{\text{planet}}^2} = ma_g \Rightarrow M_{\text{planet}} = \frac{a_g R_{\text{planet}}^2}{G}$$

The period of the astronaut's simple pendulum is related to the gravitational field a_g at the surface of the new planet:

$$T = 2\pi\sqrt{\frac{L}{a_g}} \Rightarrow a_g = \frac{4\pi^2 L}{T^2}$$

Substituting for a_g and simplifying yields:

$$M_{\text{planet}} = \frac{4\pi^2 R_{\text{planet}}^2 L}{GT^2}$$

Substitute numerical values and evaluate M_{planet}:

$$M_{\text{planet}} = \frac{4\pi^2(7550\text{ km})^2(0.500\text{ m})}{(6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(1.0\text{ s})^2} = \boxed{1.7\times10^{25}\text{ kg}}$$

91 •• A pendulum clock keeps perfect time on Earth's surface. In which case will the error be greater: if the clock is placed in a mine of depth h or if the clock is elevated to a height h? Prove your answer and assume $h << R_E$.

Picture the Problem Assume that the density of Earth ρ is constant and let m represent the mass of the clock. We can decide the question of where the clock is more accurate by applying the law of gravitation to the clock at a depth h

below/above the surface of Earth and at Earth's surface and expressing the ratios of the acceleration due to gravity below/above the surface of Earth to its value at the surface of Earth.

Express the gravitational force acting on the clock when it is at a depth h in a mine:

$$mg' = \frac{GM'm}{(R_E - h)^2}$$

where M' is the mass between the location of the clock and the center of Earth.

Express the gravitational force acting on the clock at the surface of Earth:

$$mg = \frac{GM_E m}{R_E^2}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{g'}{g} = \frac{\dfrac{GM'}{(R_E - h)^2}}{\dfrac{GM_E}{R_E^2}} = \frac{M'}{M_E}\frac{R_E^2}{(R_E - h)^2}$$

Express M':

$$M' = \rho V' = \tfrac{4}{3}\pi\rho(R_E - h)^3$$

Express M_E:

$$M_E = \rho V = \tfrac{4}{3}\pi\rho R_E^3$$

Substitute for M' and M_E to obtain:

$$\frac{g'}{g} = \frac{\tfrac{4}{3}\pi\rho(R_E - h)^3}{\tfrac{4}{3}\pi\rho R_E^3}\frac{R_E^2}{(R_E - h)^2}$$

Simplifying and solving for g' yields:

$$g' = g\left(\frac{R_E - h}{R_E}\right) = g\left(1 - \frac{h}{R_E}\right)$$

or

$$g' = g\left(1 - \frac{h}{R_E}\right) \qquad (1)$$

Express the gravitational force acting on the clock when it is at an elevation h:

$$mg'' = \frac{GM_E m}{(R_E + h)^2}$$

Express the gravitational force acting on the clock at the surface of Earth:

$$mg = \frac{GM_E m}{R_E^2}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{g''}{g}=\frac{\dfrac{GM_E}{(R_E+h)^2}}{\dfrac{GM_E}{R_E^2}}=\frac{R_E^2}{(R_E-h)^2}$$

Factoring R_E^2 from the denominator yields:

$$\frac{g''}{g}=\frac{1}{\left(1+\dfrac{h}{R_E}\right)^2}$$

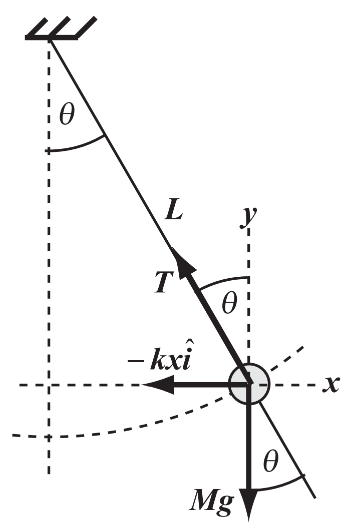
Solve for g'' to obtain:

$$g''=g\left(1+\frac{h}{R_E}\right)^{-2} \qquad (2)$$

Comparing equations (1) and (2), we see that g' is closer to g than is g''. Thus the error is greater if the clock is elevated.

92 •• Figure 14-34 shows a pendulum of length *L* with a bob of mass *M*. The bob is attached to a spring that has a force constant *k*. When the bob is directly below the pendulum support, the spring is unstressed. (*a*) Derive an expression for the period of this oscillating system for small-amplitude vibrations. (*b*) Suppose that M = 1.00 kg and *L* is such that in the absence of the spring the period is 2.00 s. What is the force constant *k* if the period of the oscillating system is 1.00 s?

Picture the Problem The pictorial representation shows this system when it has an angular displacement θ. The period of the system is related to its angular frequency according to $T = 2\pi/\omega$. We can find the equation of motion of the system by applying Newton's second law. By writing this equation in terms of θ and using a small-angle approximation, we'll find an expression for ω that we can use to express T.



(*a*) The period of the system in terms of its angular frequency is given by:

$$T=\frac{2\pi}{\omega} \qquad (1)$$

Apply $\sum \vec{F} = m\vec{a}$ to the bob:

$\sum F_x = -kx - T\sin\theta = Ma_x$

and

$\sum F_y = T\cos\theta - Mg = 0$, assuming no deviation from horizontal motion.

Eliminate T between the two equations to obtain:

$-kx - Mg\tan\theta = Ma_x$

Noting that $x = L\theta$ and $a_x = L\alpha = L\dfrac{d^2\theta}{dt^2}$, eliminate the variable x in favor of θ:

$$ML\frac{d^2\theta}{dt^2} = -kL\theta - Mg\tan\theta$$

For $\theta << 1$, $\tan\theta \approx \theta$:

$$ML\frac{d^2\theta}{dt^2} = -kL\theta - Mg\theta$$
$$= -(kL + Mg)\theta$$

or

$$\frac{d^2\theta}{dt^2} = -\left(\frac{k}{M} + \frac{g}{L}\right)\theta = -\omega^2\theta$$

where $\omega = \sqrt{\dfrac{k}{M} + \dfrac{g}{L}}$

Substitute in equation (1) to obtain:

$$T = \boxed{\frac{2\pi}{\sqrt{\dfrac{k}{M} + \dfrac{g}{L}}}}$$

(*b*) When $k = 0$ (no spring), $T = 2.00$ s, and $M = 1.00$ kg we have:

$$2.00\text{ s} = \frac{2\pi}{\sqrt{\dfrac{g}{L}}} \qquad (2)$$

With the spring present and $T = 1.00$ s we have:

$$1.00\text{ s} = \frac{2\pi}{\sqrt{k\text{ kg}^{-1} + \dfrac{g}{L}}} \qquad (3)$$

Solving equations (2) and (3) simultaneously yields:

$k = \boxed{29.6\text{ N/m}}$

93 •• **[SSM]** A block that has a mass equal to m_1 is supported from below by a frictionless horizontal surface. The block, which is attached to the end of a horizontal spring with a force constant k, oscillates with an amplitude A. When the spring is at its greatest extension and the block is instantaneously at rest, a second block of mass m_2 is placed on top of it. (*a*) What is the smallest value for the coefficient of static friction μ_s such that the second object does not slip on the first? (*b*) Explain how the total mechanical energy E, the amplitude A, the angular frequency ω, and the period T of the system are affected by the placing of m_2 on m_1, assuming that the coefficient of friction is great enough to prevent slippage.

Picture the Problem Applying Newton's second law to the first object as it is about to slip will allow us to express μ_s in terms of the maximum acceleration of the system which, in turn, depends on the amplitude and angular frequency of the oscillatory motion.

(*a*) Apply $\sum F_x = ma_x$ to the second object as it is about to slip:

$$f_{s,\max} = m_2 a_{\max}$$

Apply $\sum F_y = 0$ to the second object:

$$F_n - m_2 g = 0$$

Use $f_{s,\max} = \mu_s F_n$ to eliminate $f_{s,\max}$ and F_n between the two equations and solve for μ_s:

$$\mu_s m_2 g = m_2 a_{\max} \Rightarrow \mu_s = \frac{a_{\max}}{g}$$

Relate the maximum acceleration of the oscillator to its amplitude and angular frequency and substitute for ω^2:

$$a_{\max} = A\omega^2 = A\frac{k}{m_1 + m_2}$$

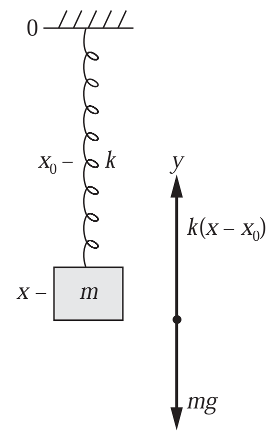
Finally, substitute for $a_{\max}$ to obtain:

$$\mu_s = \boxed{\frac{Ak}{(m_1 + m_2)g}}$$

(*b*) A is unchanged. E is unchanged because $E = \frac{1}{2}kA^2$. ω is reduced and T is increased by increasing the total mass of the system.

94 •• A 100-kg box hangs from the ceiling of a room−suspended from a spring with a force constant of 500 N/m. The unstressed length of the spring is 0.500 m. (*a*) Find the equilibrium position of the box. (*b*) An identical spring is stretched and attached to the ceiling and box and is parallel with the first spring. Find the frequency of the oscillations when the box is released. (*c*) What is the new equilibrium position of the box once it comes to rest?

Picture the Problem The pictorial representation shows the box hanging from the stretched spring and the free-body diagram when the box is in equilibrium. We can apply $\sum F_y = 0$ to the box to derive an expression for x. In (b) and (c), we can proceed similarly to obtain expressions for the effective force constant, the new equilibrium position of the box, and frequency of oscillations when the box is released.



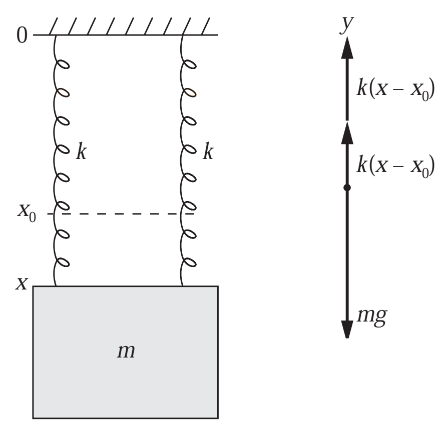
(a) Apply $\sum F_y = 0$ to the box to obtain:

$$k(x - x_0) - mg = 0 \Rightarrow x = \frac{mg}{k} + x_0$$

Substitute numerical values and evaluate x:

$$x = \frac{(100\,\text{kg})(9.81\,\text{m/s}^2)}{500\,\text{N/m}} + 0.500\,\text{m}$$
$$= \boxed{2.46\,\text{m}}$$

(b) Draw the free-body diagram for the block with the two springs exerting equal upward forces on it:



Apply $\sum F_y = 0$ to the box to obtain:

$$k(x - x_0) + k(x - x_0) - mg = 0$$

or

$$k_{\text{eff}}(x - x_0) - mg = 0 \qquad (1)$$

where $k_{\text{eff}} = 2k$

When the box is displaced from this equilibrium position and released, its motion is simple harmonic motion and its frequency is given by:

$$\omega = \sqrt{\frac{k_{\text{eff}}}{m}} = \sqrt{\frac{2k}{m}}$$

Substitute numerical values and evaluate ω:

$$\omega = \sqrt{\frac{2(500\ \text{N/m})}{100\ \text{kg}}} = \boxed{3.16\ \text{rad/s}}$$

(*c*) Solve equation (1) for x to obtain:

$$x = \frac{mg}{2k} + x_0$$

Substitute numerical values and evaluate x:

$$x = \frac{(100\ \text{kg})(9.81\ \text{m/s}^2)}{2(500\ \text{N/m})} + 0.500\ \text{m} = \boxed{1.48\ \text{m}}$$

95 •• The acceleration due to gravity g varies with geographical location because of Earth's rotation and because Earth is not exactly spherical. This was first discovered in the seventeenth century, when it was noted that a pendulum clock carefully adjusted to keep correct time in Paris lost about 90 s/d near the equator. (*a*) Show by using the differential approximation that a small change in the acceleration of gravity Δg produces a small change in the period ΔT of a pendulum given by $\Delta T / T \approx -\frac{1}{2}\Delta g / g$. (*b*) How large a change in g is needed to account for a 90 s/d change in the period?

Picture the Problem We'll differentiate the expression for the period of simple pendulum $T = 2\pi\sqrt{L/g}$ with respect to g, separate the variables, and use a differential approximation to establish that $\dfrac{\Delta T}{T} \approx -\dfrac{1}{2}\dfrac{\Delta g}{g}$.

(*a*) Express the period of a simple pendulum in terms of its length and the local value of the acceleration due to gravity:

$$T = 2\pi\sqrt{\frac{L}{g}}$$

Differentiate this expression with respect to g to obtain:

$$\frac{dT}{dg} = \frac{d}{dg}\left[2\pi\sqrt{L}g^{-1/2}\right] = -\pi\sqrt{L}g^{-3/2} = -\frac{T}{2g}$$

Separate the variables to obtain:

$$\frac{dT}{T} = -\frac{1}{2}\frac{dg}{g}$$

For $\Delta g << g$ we can approximate dT and dg by ΔT and Δg:

$$\frac{\Delta T}{T} \approx \boxed{-\frac{1}{2}\frac{\Delta g}{g}}$$

(*b*) Solve the equation in Part (*a*) for Δg:

$$\Delta g = -2g\frac{\Delta T}{T}$$

Substitute numerical values and evaluate Δg for a 90 s/d change in the period:

$$\Delta g = -2\left(9.81\,\text{m/s}^2\right)\left(-90\frac{\text{s}}{\text{d}}\times\frac{1\,\text{d}}{24\,\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\right) = \boxed{2.0\,\text{cm/s}^2}$$

96 •• A small block that has a mass equal to m_1 rests on a piston that is vibrating vertically with simple harmonic motion described by the formula $y = A\sin\omega t$. (*a*) Show that the block will leave the piston if $\omega^2 A > g$. (*b*) If $\omega^2 A = 3g$ and $A = 15$ cm, at what time will the block leave the piston?

Picture the Problem If the displacement of the block is $y = A\sin\omega t$, its acceleration is $a = -\omega^2 A\sin\omega t$.

(*a*) At maximum upward extension, the block is momentarily at rest. Its downward acceleration is g. The downward acceleration of the piston is $\omega^2 A$. Therefore, if $\omega^2 A > g$, the block will separate from the piston.

(*b*) Express the acceleration of the small block:

$$a = -A\omega^2\sin\omega t$$

For $\omega^2 A = 3g$ and $A = 15$ cm:

$$a = -3g\sin\omega t = -g$$

Solving for t yields:

$$t = \frac{1}{\omega}\sin^{-1}\left(\frac{1}{3}\right) = \sqrt{\frac{A}{3g}}\sin^{-1}\left(\frac{1}{3}\right)$$

Substitute numerical values and evaluate t:

$$t = \sqrt{\frac{0.15\,\text{m}}{3\left(9.81\,\text{m/s}^2\right)}}\sin^{-1}\left(\frac{1}{3}\right) = \boxed{24\,\text{ms}}$$

97 •• **[SSM]** Show that for the situations in Figure 14-35*a* and Figure 14-35*b* the object oscillates with a frequency $f = (1/2\pi)\sqrt{k_{\text{eff}}/m}$, where k_{eff} is given by (*a*) $k_{\text{eff}} = k_1 + k_2$, and (*b*) $1/k_{\text{eff}} = 1/k_1 + 1/k_2$. *Hint: Find the magnitude of the net force F on the object for a small displacement x and write $F = -k_{\text{eff}}x$. Note that in Part (b) the springs stretch by different amounts, the sum of which is x.*

Picture the Problem Choose a coordinate system in which the $+x$ direction is to the right and assume that the object is displaced to the right. In case (*a*), note that the two springs undergo the same displacement whereas in (*b*) they experience the same force.

(a) Express the net force acting on the object:

$$F_{\text{net}} = -k_1 x - k_2 x = -(k_1 + k_2)x = -k_{\text{eff}} x$$
where $k_{\text{eff}} = \boxed{k_1 + k_2}$

(b) Express the force acting on each spring and solve for x_2:

$$F = -k_1 x_1 = -k_2 x_2 \Rightarrow x_2 = \frac{k_1}{k_2} x_1$$

Express the total extension of the springs:

$$x_1 + x_2 = -\frac{F}{k_{\text{eff}}}$$

Solving for k_{eff} yields:

$$k_{\text{eff}} = -\frac{F}{x_1 + x_2} = -\frac{-k_1 x_1}{x_1 + x_2} = \frac{k_1 x_1}{x_1 + \frac{k_1}{k_2} x_1} = \frac{1}{\frac{1}{k_1} + \frac{1}{k_2}}$$

Take the reciprocal of both sides of the equation to obtain:

$$\frac{1}{k_{\text{eff}}} = \boxed{\frac{1}{k_1} + \frac{1}{k_2}}$$

98 •• During an earthquake, a floor oscillates horizontally in approximately simple harmonic motion. Assume it oscillates at a single frequency with a period of 0.80 s. (a) After the earthquake, you are in charge of examining the video of the floor motion and discover that a box on the floor started to slip when the amplitude reached 10 cm. From your data, determine the coefficient of static friction between the box and the floor. (b) If the coefficient of friction between the box and floor were 0.40, what would be the maximum amplitude of vibration before the box would slip?

Picture the Problem Applying Newton's second law to the box as it is about to slip will allow us to express μ_s in terms of the maximum acceleration of the platform which, in turn, depends on the amplitude and angular frequency of the oscillatory motion.

(a) Apply $\sum F_x = ma_x$ to the box as it is about to slip:

$$f_{\text{s,max}} = ma_{\text{max}}$$

Apply $\sum F_y = 0$ to the box:

$$F_{\text{n}} - mg = 0$$

Use $f_{\text{s,max}} = \mu_{\text{s}} F_{\text{n}}$ to eliminate $f_{\text{s,max}}$ and F_{n} between the two equations:

$$\mu_{\text{s}} mg = ma_{\text{max}} \text{ and } \mu_{\text{s}} = \frac{a_{\text{max}}}{g}$$

Relate the maximum acceleration of the oscillator to its amplitude and angular frequency:

$$a_{max} = A\omega^2$$

Substitute for a_{max} in the expression for μ_s:

$$\mu_s = \frac{A\omega^2}{g} = \frac{4\pi^2 A}{T^2 g}$$

Substitute numerical values and evaluate μ_s:

$$\mu_s = \frac{4\pi^2(0.10\,\text{m})}{(0.80\,\text{s})^2(9.81\,\text{m/s}^2)} = \boxed{0.63}$$

(*b*) Solve the equation derived above for A_{max}:

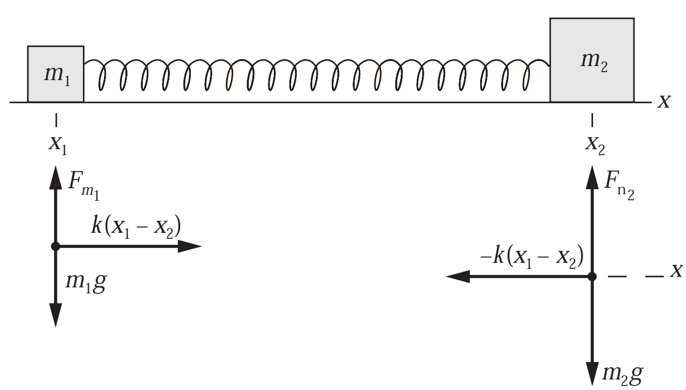
$$A_{max} = \frac{\mu_s g}{\omega^2} = \frac{\mu_s g T^2}{4\pi^2}$$

Substitute numerical values and evaluate A_{max}:

$$A_{max} = \frac{(0.40)(9.81\,\text{m/s}^2)(0.80\,\text{s})^2}{4\pi^2} = \boxed{6.4\,\text{cm}}$$

99 •• If we attach two blocks of masses m_1 and m_2 to either end of a spring of force constant k and set them into oscillation by releasing them from rest with the spring stretched, show that the oscillation frequency is given by $\omega = (k/\mu)^{1/2}$, where $\mu = m_1m_2/(m_1 + m_2)$ is the reduced mass of the system.

Picture the Problem The pictorial representation shows the two blocks connected by the spring and displaced from their equilibrium positions. We can apply Newton's second law to each of these coupled oscillators and solve the resulting equations simultaneously to obtain the equation of motion of the coupled oscillators. We can then compare this equation and its solution to the equation of motion of the simple harmonic oscillator and its solution to show that the oscillation frequency is $\omega = (k/\mu)^{1/2}$ where $\mu = m_1m_2/(m_1 + m_2)$.



Apply $\sum \vec{F} = m\vec{a}$ to the block whose mass is m_1 and solve for its acceleration:

$$k(x_1 - x_2) = m_1 a_1 = m_1 \frac{d^2 x_1}{dt^2}$$

or

$$a_1 = \frac{d^2 x_1}{dt^2} = \frac{k}{m_1}(x_1 - x_2)$$

Apply $\sum \vec{F} = m\vec{a}$ to the block whose mass is m_2 and solve for its acceleration:

$$-k(x_1 - x_2) = m_2 a_2 = m_2 \frac{d^2 x_2}{dt^2}$$

or

$$a_2 = \frac{d^2 x_2}{dt^2} = \frac{k}{m_2}(x_2 - x_1)$$

Subtract the first equation from the second to obtain:

$$\frac{d^2(x_2 - x_1)}{dt^2} = \frac{d^2 x}{dt^2} = k\left(\frac{1}{m_1} + \frac{1}{m_2}\right)x$$

where $x = x_2 - x_1$

The reduced mass of the system is:

$$\frac{1}{\mu} = \frac{1}{m_1} + \frac{1}{m_2} \Rightarrow \mu = \frac{m_1 m_2}{m_1 + m_2}$$

Substitute to obtain:

$$\frac{d^2 x}{dt^2} = -\frac{k}{\mu}x \qquad (1)$$

Compare this equation to the equation of the simple harmonic oscillator:

$$\frac{d^2 x}{dt^2} = -\frac{k}{m}x$$

The solution to this equation is:

$$x = x_0 \cos(\omega t + \delta)$$

where $\omega = \sqrt{\frac{k}{m}}$

Because of the similarity of the two differential equations, the solution to equation (1) must be:

$$x = x_0 \cos(\omega t + \delta)$$

where $\omega = \boxed{\sqrt{\frac{k}{\mu}}}$ and $\mu = \boxed{\frac{m_1 m_2}{m_1 + m_2}}$

100 •• In one of your chemistry labs you determine that one of the vibrational modes of the HCl molecule has a frequency of 8.969×10^{13} Hz. Using the result of Problem 99, find the effective ″spring constant″ between the H atom and the Cl atom in the HCl molecule.

Picture the Problem We can use $\omega = (k/\mu)^{1/2}$ and $\mu = m_1 m_2/(m_1 + m_2)$ from Problem 99 to find the spring constant for the HCl molecule.

Use the result of Problem 99 to relate the oscillation frequency to the force constant and reduced mass of the HCl molecule:

$$\omega = \sqrt{\frac{k}{\mu}} \Rightarrow k = \mu\omega^2$$

Express the reduced mass of the HCl molecule:

$$\mu = \frac{m_1 m_2}{m_1 + m_2}$$

Substitute for μ to obtain:

$$k = \frac{m_1 m_2 \omega^2}{m_1 + m_2}$$

Express the masses of the hydrogen and Cl atoms:

$m_1 = 1\text{ amu} = 1.67\times10^{-27}\text{ kg}$
and
$m_2 = 35.45\text{ amu} = 5.92\times10^{-26}\text{ kg}$

Substitute numerical values and evaluate k:

$$k = \frac{\left(1.673\times10^{-27}\text{ kg}\right)\left(5.92\times10^{-26}\text{ kg}\right)\left(8.969\times10^{13}\text{ s}^{-1}\right)^2}{1.673\times10^{-27}\text{ kg} + 5.92\times10^{-26}\text{ kg}} = \boxed{13.1\text{ N/m}}$$

101 •• If a hydrogen atom in HCl were replaced by a deuterium atom (forming DCl) in Problem 100, what would be the new vibration frequency of the molecule? Deuterium consists of 1 proton and 1 neutron.

Picture the Problem In Problem 100, we derived an expression for the oscillation frequency of a spring-and-two-block system as a function of the force constant of the spring and the reduced mass of the two blocks. We can solve this problem, assuming that the "spring constant" does not change, by using the result of Problem 101 and the reduced mass of a deuterium atom and a Cl atom in the equation for the oscillation frequency.

Use the result of Problem 100 to relate the oscillation frequency to the force constant and reduced mass of the DCl molecule:

$$\omega = \sqrt{\frac{k}{\mu}}$$

Express the reduced mass of the DCl molecule:

$$\mu = \frac{m_1 m_2}{m_1 + m_2}$$

The masses of the deuterium and Cl atoms are:

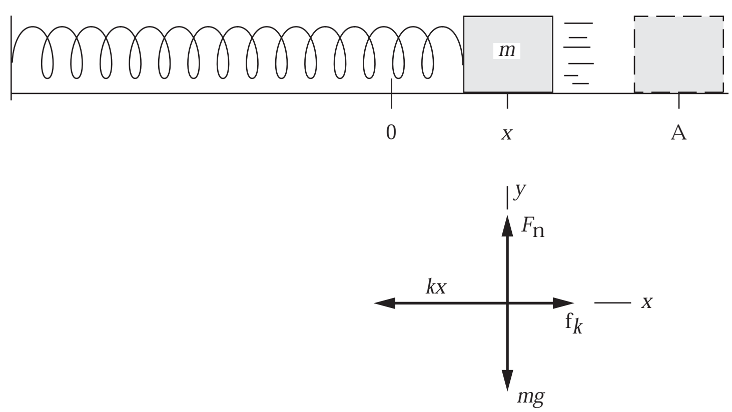
$m_1 = 2\text{ amu} = 3.34\times10^{-27}\text{ kg}$
and
$m_2 = 35.45\text{ amu} = 5.92\times10^{-26}\text{ kg}$

Substitute numerical values and evaluate ω:

$$\omega = \sqrt{\frac{13.1\,\text{N/m}}{\frac{(3.34\times10^{-27}\,\text{kg})(5.92\times10^{-26}\,\text{kg})}{3.34\times10^{-27}\,\text{kg}+5.92\times10^{-26}\,\text{kg}}}} = \boxed{6.44\times10^{13}\,\text{rad/s}}$$

102 ••• A block of mass m on a horizontal table is attached to a spring of force constant k, as shown in Figure 14-36. The coefficient of kinetic friction between the block and the table is μ_k. The spring is unstressed if the block is at the origin (x = 0), and the +x direction is to the right. The spring is stretched a distance A, where $kA > \mu_k mg$, and the block is released. (*a*) Apply Newton's second law to the block to obtain an equation for its acceleration d^2x/dt^2 for the first half-cycle, during which the block is moving to the left. Show that the resulting equation can be written as $d^2x'/dt^2 = -\omega^2 x'$, where $\omega = \sqrt{k/m}$ and $x' = x - x_0$, with $x_0 = \mu_k mg/k = \mu_k g/\omega^2$. (*b*) Repeat Part (*a*) for the second half-cycle as the block moves to the right, and show that $d^2x''/dt^2 = -\omega^2 x''$, where $x'' = x + x_0$ and x_0 has the same value. (*c*) Use a **spreadsheet program** to graph the first 5 half-cycles for $A = 10x_0$. Describe the motion, if any, after the fifth half-cycle.

Picture the Problem The pictorial representation shows the block moving from right to left with an instantaneous displacement x from its equilibrium position. The free-body diagram shows the forces acting on the block during the half-cycles that it moves from right to left. When the block is moving from left to right, the directions of the kinetic friction force and the restoring force exerted by the spring are reversed. We can apply Newton's second law to these motions to obtain the equations given in the problem statements and then use their solutions to plot the graph called for in (*c*).



(*a*) Apply $\sum F_x = ma_x$ to the block while it is moving to the left to obtain:

$$f_k - kx = m\frac{d^2x}{dt^2}$$

Using $f_k = \mu_k F_n = \mu_k mg$, eliminate f_k in the equation of motion:

$$m\frac{d^2x}{dt^2} = -kx + \mu_k mg$$

or

$$m\frac{d^2x}{dt^2} = -k\left(x - \frac{\mu_k mg}{k}\right)$$

Let $x_0 = \dfrac{\mu_k mg}{k}$ to obtain:

$$m\frac{d^2x}{dt^2} = -k(x - x_0)$$

or

$$\boxed{\frac{d^2x'}{dt^2} = -\frac{k}{m}x' = -\omega^2 x'}$$

provided $x' = x - x_0$ and

$$x_0 = \boxed{\frac{\mu_k mg}{k} = \frac{\mu_k g}{\omega^2}}$$

The solution to the equation of motion is:

$$x' = x_0' \cos(\omega t + \delta)$$

and its derivative is

$$v' = -\omega x_0' \sin(\omega t + \delta)$$

The initial conditions are:

$$x'(0) = x - x_0 \text{ and } v'(0) = 0$$

Apply these conditions to obtain:

$$x'(0) = x_0' \cos\delta = x - x_0$$

and

$$v'(0) = -\omega x_0' \sin\delta = 0$$

Solve these equations simultaneously to obtain:

$$\delta = 0 \text{ and } x_0' = x - x_0$$

and

$$x' = (x - x_0)\cos\omega t$$

or

$$x = \boxed{(x - x_0)\cos\omega t + x_0} \qquad (1)$$

(*b*) Apply $\sum \vec{F} = m\vec{a}$ to the block while it is moving to the right to obtain:

$$-f_k - kx = m\frac{d^2x}{dt^2}$$

Using $f_k = \mu_k F_n = \mu_k mg$, eliminate f_k in the equation of motion:

$$m\frac{d^2x}{dt^2} = -kx - \mu_k mg$$

or

$$m\frac{d^2x}{dt^2} = -k\left(x + \frac{\mu_k mg}{k}\right)$$

Let $x_0 = \dfrac{\mu_k mg}{k}$ to obtain:

$$m\frac{d^2x}{dt^2} = -k(x + x_0)$$

or

$$\boxed{\frac{d^2x''}{dt^2} = -\frac{k}{m}x'' = -\omega^2 x''}$$

provided $x'' = x + x_0$ and

$$x_0 = \boxed{\frac{\mu_k mg}{k} = \frac{\mu_k g}{\omega^2}}.$$

The solution to the equation of motion is:

$$x'' = x_0'' \cos(\omega t + \delta)$$

and its derivative is

$$v'' = -\omega x_0'' \sin(\omega t + \delta)$$

The initial conditions are:

$$x''(0) = x + x_0 \text{ and } v''(0) = 0$$

Apply these conditions to obtain:

$$x''(0) = x_0'' \cos\delta = x + x_0$$

and

$$v''(0) = -\omega x_0'' \sin\delta = 0$$

Solve these equations simultaneously to obtain:

$$\delta = 0 \text{ and } x_0'' = x + x_0$$

and

$$x'' = (x + x_0)\cos\omega t$$

or

$$\boxed{x = (x + x_0)\cos\omega t - x_0} \qquad (2)$$

(*c*) A spreadsheet program to calculate the position of the oscillator as a function of time (equations (1) and (2)) is shown below. The constants used in the position functions (x_0 = 1 m and T = 2 s were used for simplicity) and the formulas used to calculate the positions are shown in the table. *After each half-period, one must compute a new amplitude for the oscillation, using the final value of the position from the last half-period.*

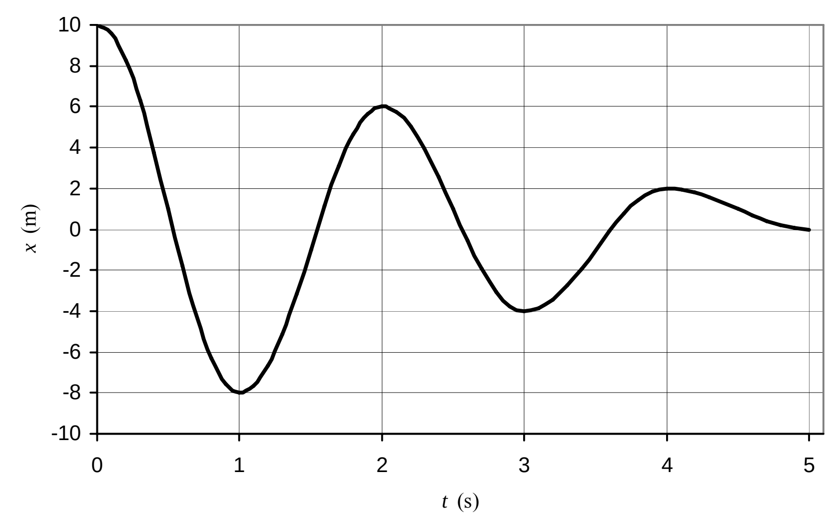
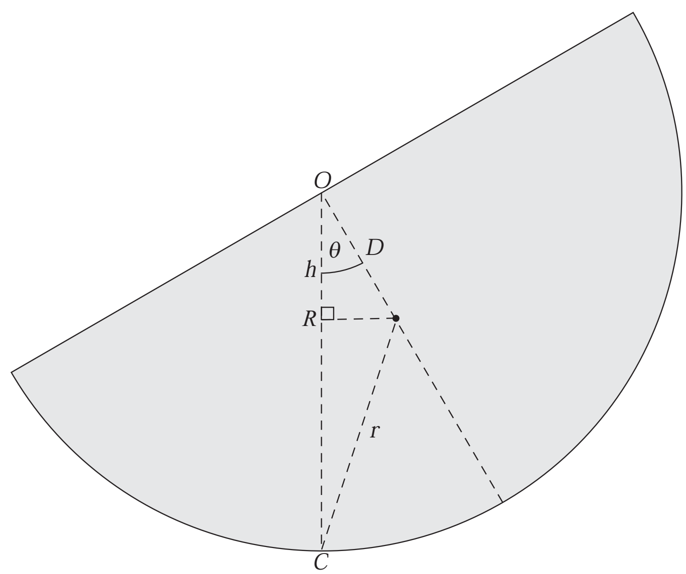
The following graph was plotted using the data from columns C (t) and D (x).

$\boxed{\text{Note that the motion of the block ceases after five half - cycles.}}$



103 ••• Figure 14-37 shows a uniform solid half-cylinder of mass M and radius R resting on a horizontal surface. If one side of this cylinder is pushed down slightly and then released, the half-cylinder will oscillate about its equilibrium position. Determine the period of this oscillation.

Picture the Problem The diagram shows the half-cylinder displaced from its equilibrium position through an angle θ. The frequency of its motion will be found by expressing the mechanical energy E in terms of θ and $d\theta/dt$. For small θ we will obtain an equation of the form $E = \frac{1}{2}\kappa\theta^2 + \frac{1}{2}I\left(\frac{d\theta}{dt}\right)^2$. Differentiating both sides of this equation with respect to time will lead to $0 = \left(\kappa\theta + I\frac{d^2\theta}{dt^2}\right)\frac{d\theta}{dt}$, an equation that must be valid at all times. Because the situation of interest to us requires that $d\theta/dt$ is not always equal to zero, we have $0 = \kappa\theta + I\frac{d^2\theta}{dt^2}$ or $\frac{d^2\theta}{dt^2} + \frac{\kappa}{I}\theta = 0$, the equation of simple harmonic motion with $\omega^2 = \kappa/I$. We'll show that the distance from O to the center of mass D, is given by $D = \frac{4R}{3\pi}$, and let the distance from the contact point C to the center of mass be r. Finally, we'll take the potential energy to be zero where θ is zero and assume that there is no slipping.



Apply conservation of energy to obtain:

$$E = U + K$$

$$= Mg(h - D) + \frac{1}{2}I_C\left(\frac{d\theta}{dt}\right)^2 \quad (1)$$

From Table 9-1, the moment of inertia of a solid cylinder about an axis perpendicular to its face and through its center is given by:

$$I_{0,\,\text{solid cylinder}} = \frac{1}{2}(2M)R^2 = MR^2$$

where M is the mass of the half-cylinder.

Express the moment of inertia of the half-cylinder about the same axis:

$$I_{0,\text{ half cylinder}} = I_0 = \frac{1}{2}\left[MR^2\right] = \frac{1}{2}MR^2$$

Use the parallel-axis theorem to relate I_{cm} to I_0:

$$I_0 = I_{cm} + MD^2$$

Substitute for I_0 and solve for I_{cm}:

$$I_{cm} = I_0 - D^2M = \frac{1}{2}MR^2 - D^2M$$

Apply the parallel-axis theorem a second time to obtain an expression for I_C:

$$\begin{aligned} I_C &= \frac{1}{2}MR^2 - D^2M + Mr^2 \\ &= M\left(\frac{1}{2}R^2 - D^2 + r^2\right) \end{aligned} \qquad (2)$$

Apply the law of cosines to obtain:

$$r^2 = R^2 + D^2 - 2RD\cos\theta$$

Substitute for r^2 in equation (2) to obtain:

$$I_C = M\left(\frac{1}{2}R^2 - D^2 + R^2 + D^2 - 2RD\cos\theta\right) = MR^2\left(\frac{3}{2} - 2\frac{D}{R}\cos\theta\right)$$

Substitute for h and I_C in equation (1):

$$E = MgD(1-\cos\theta) + \frac{1}{2}MR^2\left(\frac{3}{2} - 2\frac{D}{R}\cos\theta\right)\left(\frac{d\theta}{dt}\right)^2$$

Use the small angle approximation $\cos\theta \approx 1 - \frac{1}{2}\theta^2$ to obtain:

$$E = \frac{1}{2}MgD\theta^2 + \frac{1}{2}MR^2\left(\frac{3}{2} - \frac{D}{R}\left[2-\theta^2\right]\right)\left(\frac{d\theta}{dt}\right)^2$$

Because $\theta^2 << 2$, we can neglect the θ^2 in the square brackets to obtain:

$$E = \frac{1}{2}MgD\theta^2 + \frac{1}{2}MR^2\left(\frac{3}{2} - 2\frac{D}{R}\right)\left(\frac{d\theta}{dt}\right)^2$$

Differentiating both sides with respect to time and simplifying yields:

$$R^2\left(\frac{3}{2}-2\frac{D}{R}\right)\left(\frac{d^2\theta}{dt^2}\right)+gD\theta=0\,,$$

or

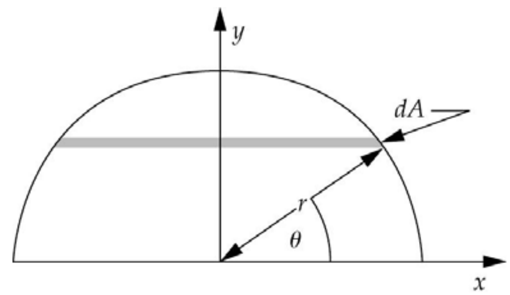
$$\frac{d^2\theta}{dt^2}+\frac{gD}{R^2\left(\frac{3}{2}-2\frac{D}{R}\right)}\theta=0\,,$$

the equation of simple harmonic motion with $\omega^2=\dfrac{gD}{R^2\left(\frac{3}{2}-2\frac{D}{R}\right)}$. (3)

D is the y coordinate of the center of mass of the semicircular disk shown. A surface element of area dA is shown in the diagram. Because the disk is a continuous object, we'll use

$$M\vec{r}_{\rm cm}=\int\vec{r}dm$$

to find $y_{\rm cm}=D$.



Express the coordinates of the center of mass of the semicircular disk:

$x_{\rm cm}=0$ by symmetry.

$$y_{\rm cm}=D=\frac{\int y\sigma\,dA}{M}$$

Express y as a function of r and θ:

$$y=r\sin\theta$$

Express dA in terms of r and θ:

$$dA=r\,d\theta\,dr$$

Substitute for y and dA and evaluate D:

$$D=\frac{\sigma\int_0^R\int_0^\pi r^2\sin\theta\,d\theta\,dr}{M}=\frac{2\sigma}{M}\int_0^R r^2dr$$

$$=\frac{2\sigma}{3M}R^3$$

Express M as a function of r and θ:

$$M=\sigma A_{\text{half disk}}=\tfrac{1}{2}\sigma\pi R^2$$

Substituting for M and simplifying yields:

$$D=\frac{2\sigma}{3\left(\frac{1}{2}\sigma\pi R^2\right)}R^3=\boxed{\frac{4}{3\pi}R}$$

Substitute for D in equation (3) and simplify to obtain:

$$\omega^2 = \frac{\frac{4}{3\pi}}{\left(\frac{3}{2} - \frac{8}{3\pi}\right)}\frac{g}{R} = \left(\frac{8}{9\pi - 16}\right)\frac{g}{R}$$

The period of the motion is given by:

$$T = \frac{2\pi}{\omega}$$

Substituting for ω and simplifying yields:

$$T = 2\pi\sqrt{\left(\frac{9\pi - 16}{8}\right)\frac{R}{g}} = \boxed{7.78\sqrt{\frac{R}{g}}}$$

104 ••• A straight tunnel is dug through Earth as shown in Figure 14-38. Assume that the walls of the tunnel are frictionless. (*a*) The gravitational force exerted by Earth on a particle of mass *m* at a distance *r* from the center of Earth when $r < R_E$ is $F_r = -\left(GmM_{\mathrm{E}} / R_{\mathrm{E}}^3\right)r$, where M_{E} is the mass of Earth and R_{E} is its radius. Show that the net force on a particle of mass *m* at a distance *x* from the middle of the tunnel is given by $F_x = -\left(GmM_{\mathrm{E}} / R_{\mathrm{E}}^3\right)x$, and that the motion of the particle is therefore simple harmonic motion. (*b*) Show that the period of the motion is independent of the length of the tunnel and is given by $T = 2\pi\sqrt{R_{\mathrm{E}}/g}$. (*c*) Find its numerical value in minutes.

Picture the Problem The net force acting on the particle as it moves in the tunnel is the *x*-component of the gravitational force acting on it. We can find the period of the particle from the angular frequency of its motion. We can apply Newton's second law to the particle in order to express ω in terms of the radius of Earth and the acceleration due to gravity at the surface of Earth.

(*a*) From the figure we see that:

$$F_x = F_r \sin\theta = -\frac{GmM_{\mathrm{E}}}{R_{\mathrm{E}}^3} r \frac{x}{r} = \boxed{-\frac{GmM_{\mathrm{E}}}{R_{\mathrm{E}}^3} x}$$

Because this force is a linear restoring force, the motion of the particle is simple harmonic motion.

(*b*) Express the period of the particle as a function of its angular frequency:

$$T = \frac{2\pi}{\omega} \qquad (1)$$

Apply $\sum F_x = ma_x$ to the particle:

$$-\frac{GmM_{\mathrm{E}}}{R_{\mathrm{E}}^3} x = ma$$

Solving for a yields:

$$a = -\frac{GM_E}{R_E^3}x = -\omega^2 x$$

where $\omega = \sqrt{\frac{GM_E}{R_E^3}}$

Use $GM_E = gR_E^2$ to simplify ω:

$$\omega = \sqrt{\frac{gR_E^2}{R_E^3}} = \sqrt{\frac{g}{R_E}}$$

Substitute in equation (1) to obtain:

$$T = \frac{2\pi}{\sqrt{\frac{g}{R_E}}} = \boxed{2\pi\sqrt{\frac{R_E}{g}}}$$

(c) Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{6.37\times10^6\ \text{m}}{9.81\,\text{m/s}^2}} = 5.06\times10^3\ \text{s}$$

$$= \boxed{84.4\,\text{min}}$$

105 ••• [SSM] In this problem, derive the expression for the average power delivered by a driving force to a driven oscillator (Figure 14-39).
(a) Show that the instantaneous power input of the driving force is given by

$$P = Fv = -A\,\omega F_0 \cos\omega t \sin(\omega t - \delta).$$

(b) Use the identity $\sin(\theta_1 - \theta_2) = \sin\theta_1\cos\theta_2 - \cos\theta_1\sin\theta_2$ to show that the equation in (a) can be written as

$$P = A\omega F_0 \sin\delta\cos^2\omega t - A\omega F_0\cos\delta\cos\omega t\sin\omega t$$

(c) Show that the average value of the second term in your result for (b) over one or more periods is zero, and that therefore $P_{av} = \frac{1}{2}A\omega F_0 \sin\delta$.
(d) From Equation 14-56 for $\tan\delta$, construct a right triangle in which the side opposite the angle δ is $b\omega$ and the side adjacent is $m(\omega_0^2 - \omega^2)$, and use this triangle to show that

$$\sin\delta = \frac{b\omega}{\sqrt{m^2(\omega_0^2-\omega^2)^2 + b^2\omega^2}} = \frac{b\omega A}{F_0}.$$

(e) Use your result for Part (d) to eliminate ωA from your result for Part (c) so that the average power input can be written as

$$P_{av} = \frac{1}{2}\frac{F_0^2}{b}\sin^2\delta = \frac{1}{2}\left[\frac{b\omega^2F_0^2}{m^2(\omega_0^2-\omega^2)^2 + b^2\omega^2}\right].$$

Picture the Problem We can follow the step-by-step instructions provided in the problem statement to obtain the desired results.

(*a*) Express the average power delivered by a driving force to a driven oscillator:

$P = \vec{F}\cdot\vec{v} = Fv\cos\theta$
or, because θ is 0°,
$P = Fv$

Express F as a function of time:

$F = F_0\cos\omega t$

Express the position of the driven oscillator as a function of time:

$x = A\cos(\omega t - \delta)$

Differentiate this expression with respect to time to express the velocity of the oscillator as a function of time:

$v = -A\omega\sin(\omega t - \delta)$

Substitute to express the average power delivered to the driven oscillator:

$$P = (F_0\cos\omega t)[-A\omega\sin(\omega t - \delta)] = \boxed{-A\omega F_0\cos\omega t\sin(\omega t - \delta)}$$

(*b*) Expand $\sin(\omega t - \delta)$ to obtain:

$\sin(\omega t - \delta) = \sin\omega t\cos\delta - \cos\omega t\sin\delta$

Substitute in your result from (*a*) and simplify to obtain:

$$P = -A\omega F_0\cos\omega t(\sin\omega t\cos\delta - \cos\omega t\sin\delta) = \boxed{\begin{array}{l} A\omega F_0\sin\delta\cos^2\omega t \\ \quad - A\omega F_0\cos\delta\cos\omega t\sin\omega t \end{array}}$$

(*c*) Integrate $\sin\theta\cos\theta$ over one period to determine $\langle\sin\theta\cos\theta\rangle$:

$$\langle\sin\theta\cos\theta\rangle = \frac{1}{2\pi}\left[\int_0^{2\pi}\sin\theta\cos\theta d\theta\right] = \frac{1}{2\pi}\left[\frac{1}{2}\sin^2\theta\Big|_0^{2\pi}\right] = 0$$

Integrate $\cos^2\theta$ over one period to determine $\langle\cos^2\theta\rangle$:

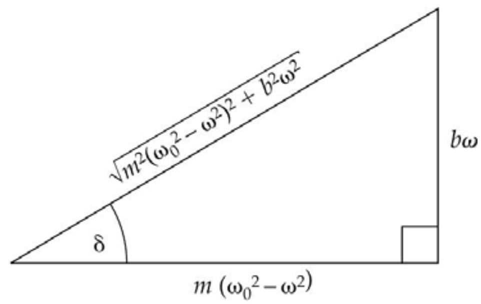
$$\langle\cos^2\theta\rangle = \frac{1}{2\pi}\int_0^{2\pi}\cos^2\theta d\theta = \frac{1}{2\pi}\left[\frac{1}{2}\int_0^{2\pi}(1+\cos 2\theta)d\theta\right] = \frac{1}{2\pi}\left[\tfrac{1}{2}\int_0^{2\pi}d\theta + \tfrac{1}{2}\int_0^{2\pi}\cos 2\theta d\theta\right] = \frac{1}{2\pi}(\pi + 0) = \frac{1}{2}$$

Substitute and simplify to express P_{av}:

$$P_{\text{av}} = A\omega F_0 \sin\delta\left\langle\cos^2\omega t\right\rangle - A\omega F_0\cos\delta\left\langle\cos\omega t\sin\omega t\right\rangle = \tfrac{1}{2}A\omega F_0\sin\delta - A\omega F_0\cos\delta(0) = \boxed{\tfrac{1}{2}A\omega F_0\sin\delta}$$

(*d*) Construct a triangle that is consistent with

$$\tan\delta = \frac{b\omega}{m\left(\omega_0^2-\omega^2\right)}:$$



Using the triangle, express $\sin\delta$:

$$\sin\delta = \boxed{\frac{b\omega}{\sqrt{m^2\left(\omega_0^2-\omega^2\right)^2+b^2\omega^2}}}$$

Using Equation 14-56, reduce this expression to the simpler form:

$$\sin\delta = \boxed{\frac{b\omega A}{F_0}}$$

(*e*) Solve $\sin\delta = \frac{b\omega A}{F_0}$ for ω:

$$\omega = \frac{F_0}{bA}\sin\delta$$

Substitute in the expression for P_{av} to eliminate ω:

$$P_{\text{av}} = \boxed{\frac{F_0^2}{2b}\sin^2\delta}$$

Substitute for $\sin\delta$ from (*d*) to obtain:

$$P_{\text{av}} = \boxed{\frac{1}{2}\left[\frac{b\omega^2F_0^2}{m^2\left(\omega_0^2-\omega^2\right)^2+b^2\omega^2}\right]}$$

106 ••• In this problem, you are to use the result of Problem 105 to derive Equation 14-51. At resonance, the denominator of the fraction in brackets in Problem 105(*e*) is $b^2\omega_0^2$ and P_{av} has its maximum value. For a sharp resonance, the variation in ω in the numerator in this equation can be neglected. Then the power input will be half its maximum value at the values of ω, for which the denominator is $2b^2\omega_0^2$.

(*a*) Show that ω then satisfies $m^2\left(\omega-\omega_0\right)^2\left(\omega+\omega_0\right)^2 \approx b^2\omega_0^2$.

(*b*) Using the approximation $\omega+\omega_2 \approx 2\omega_0$, show that $\omega-\omega_0 \approx \pm b/2m$.

(*c*) Express b in terms of Q.

(*d*) Combine the results of (*b*) and (*c*) to show that there are two values of ω for which the power input is half that at resonance and that they are given by

$$\omega_1 = \omega_0 - \frac{\omega_0}{2Q} \text{ and } \omega_2 = \omega_0 - \frac{\omega_0}{2Q}$$

Therefore, $\omega_2 - \omega_1 = \Delta\omega = \omega_0 / Q$, which is equivalent to Equation 14-51.

Picture the Problem We can follow the step-by-step instructions given in the problem statement to derive the given results.

(*a*) Express the condition on the denominator of Equation 14-56 when the power input is half its maximum value:

$$m^2\left(\omega_0^2 - \omega^2\right)^2 + b^2\omega^2 = 2b^2\omega_0^2$$

and, for a sharp resonance,

$$m^2\left(\omega_0^2 - \omega^2\right)^2 \approx b^2\omega_0^2$$

Factor the difference of two squares to obtain:

$$m^2\left[(\omega_0 - \omega)(\omega_0 + \omega)\right]^2 \approx b^2\omega_0^2$$

or

$$\boxed{m^2(\omega_0 - \omega)^2(\omega_0 + \omega)^2 \approx b^2\omega_0^2}$$

(*b*) Use the approximation $\omega + \omega_0 \approx 2\omega_0$ to obtain:

$$m^2(\omega_0 - \omega)^2(2\omega_0)^2 \approx b^2\omega_0^2$$

Solving for $\omega_0 - \omega$ yields:

$$\omega_0 - \omega = \boxed{\pm\frac{b}{2m}} \qquad (1)$$

(*c*) Using its definition, express *Q*:

$$Q = \frac{\omega_0 m}{b} \Rightarrow b = \boxed{\frac{\omega_0 m}{Q}}$$

(*d*) Substitute for *b* in equation (1) to obtain:

$$\omega_0 - \omega = \pm\frac{\omega_0}{2Q} \Rightarrow \omega = \omega_0 \pm \frac{\omega_0}{2Q}$$

Express the two values of ω:

$$\omega_+ = \boxed{\omega_0 + \frac{\omega_0}{2Q}} \text{ and } \omega_- = \boxed{\omega_0 - \frac{\omega_0}{2Q}}$$

Remarks: Note that the width of the resonance at half-power is $\Delta\omega = \omega_+ - \omega_- = \omega_0/Q$, in agreement with Equation 14-51.

107 ••• The Morse potential, which is often used to model interatomic forces, can be written in the form $U(r) = D\left(1 - e^{-\beta(r - r_0)}\right)^2$, where *r* is the distance between the two atomic nuclei. (*a*) Using a **spreadsheet program** or **graphing calculator**, make a graph of the Morse potential using D = 5.00 eV, β = 0.20 nm^{-1}, and

$r_0 = 0.750$ nm. (*b*) Determine the equilibrium separation and "spring constant" for small displacements from equilibrium for the Morse potential. (*c*) Determine an expression for the oscillation frequency for a *homonuclear* diatomic molecule (that is, two of the same atoms), where the atoms each have mass *m*.

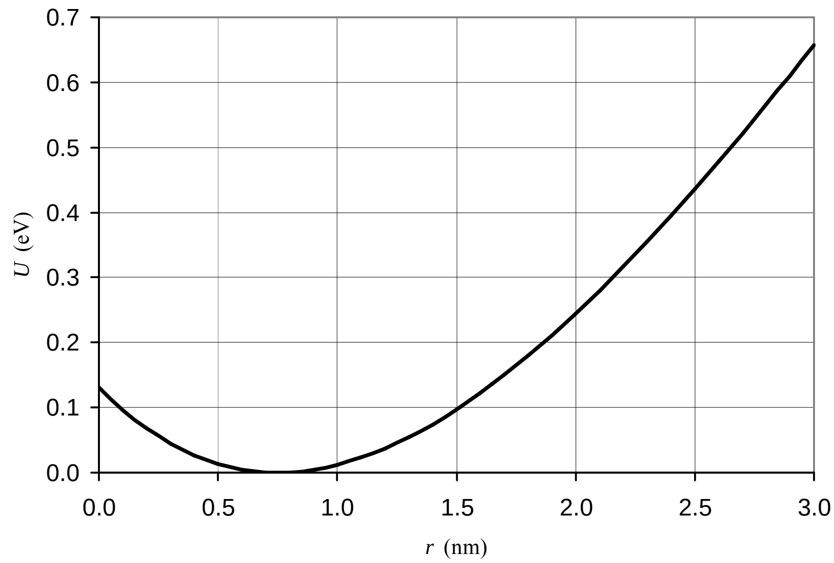
Picture the Problem We can find the equilibrium separation for the Morse potential by setting $dU/dr = 0$ and solving for *r*. The second derivative of *U* will give the "spring constant" for small displacements from equilibrium. In (*c*), we can use $\omega = \sqrt{k/\mu}$, where *k* is our result from (*b*) and μ is the reduced mass of a homonuclear diatomic molecule, to find the oscillation frequency of the molecule.

(*a*) A spreadsheet program to calculate the Morse potential as a function of *r* is shown below. The constants and cell formulas used to calculate the potential are shown in the table.

Cell	Content/Formula	Algebraic Form
B1	5	D
B2	0.2	β
C9	C8 + 0.1	$r + \Delta r$
D8	$B$1*(1−EXP(−$B$2*(C8−$B$3)))^2	$D\left[1-e^{-\beta(r-r_0)}\right]^2$

	A	B	C	D
1	D=	5	eV	
2	β=	0.2	nm^{-1}	
3	r_0=	0.75	nm	
4				
5				
6			r	$U(r)$
7			(nm)	(eV)
8			0.0	0.13095
9			0.1	0.09637
10			0.2	0.06760
11			0.3	0.04434
12			0.4	0.02629
235			22.7	4.87676
236			22.8	4.87919
237			22.9	4.88156
238			23.0	4.88390
239			23.1	4.88618

The following graph was plotted using the data from columns C (r) and D ($U(r)$).



(*b*) Differentiate the Morse potential with respect to r to obtain:

$$\frac{dU}{dr} = \frac{d}{dr}\left\{D\left[1-e^{-\beta(r-r_0)}\right]^2\right\} = -2\beta D\left[1-e^{-\beta(r-r_0)}\right]$$

This derivative is equal to zero for extrema:

$$-2\beta D\left[1-e^{-\beta(r-r_0)}\right] = 0 \Rightarrow r = \boxed{r_0}$$

Evaluate the second derivative of $U(r)$ to obtain:

$$\frac{d^2U}{dr^2} = \frac{d}{dr}\left\{-2\beta D\left[1-e^{-\beta(r-r_0)}\right]\right\} = 2\beta^2 D e^{-\beta(r-r_0)}$$

Evaluate this derivative at $r = r_0$:

$$\left.\frac{d^2U}{dr^2}\right|_{r=r_0} = 2\beta^2 D \qquad (1)$$

Recall that the potential function for a simple harmonic oscillator is:

$$U = \tfrac{1}{2}kx^2$$

Differentiate this expression twice to obtain:

$$\frac{d^2U}{dx^2} = k$$

By comparison with equation (1) we have:

$$k = \boxed{2\beta^2 D}$$

(c) Express the oscillation frequency of the diatomic molecule:

$$\omega=\sqrt{\frac{k}{\mu}}$$

where μ is the reduced mass of the molecule.

Express the reduced mass of the homonuclear diatomic molecule:

$$\mu=\frac{m_1 m_2}{m_1+m_2}=\frac{m^2}{2m}=\frac{m}{2}$$

Substitute for ω and simplify to obtain:

$$\omega=\sqrt{\frac{2\beta^2 D}{\frac{m}{2}}}=\boxed{2\beta\sqrt{\frac{D}{m}}}$$

Remarks: An alternative approach in (*b*) is to expand the Morse potential in a Taylor series

$$\boldsymbol{U(r)=U(r_0)+(r-r_0)U'(r_0)+\frac{1}{2!}(r-r_0)^2 U''(r_0)+\textbf{higher order terms}}$$

to obtain $\boldsymbol{U(r)\approx\beta^2 D(r-r_0)^2}$. Comparing this expression to the energy of a spring-and-mass oscillator we see that, as was obtained above, $\boldsymbol{k=2\beta^2 D}$.

Chapter 15
Traveling Waves

Conceptual Problems

1 • [SSM] A rope hangs vertically from the ceiling. A pulse is sent up the rope. Does the pulse travel faster, slower, or at a constant speed as it moves toward the ceiling? Explain your answer.

Determine the Concept The speed of a transverse wave on a uniform rope increases with increasing tension. The waves on the rope move faster as they move toward the ceiling because the tension increases due to the weight of the rope below the pulse.

2 • A pulse on a horizontal taut string travels to the right. If the rope's mass per unit length decreases to the right, what happens to the speed of the pulse as it travels to the right? (*a*) It slows down. (*b*) It speeds up. (*c*) Its speed is constant. (*d*) You cannot tell from the information given.

Determine the Concept The speed v of a pulse on the string varies with the tension F_T in the string and its mass per unit length μ according to $v=\sqrt{F_T/\mu}$. Because the rope's mass per unit length decreases to the right, the speed of the pulse increases. $\boxed{(b)}$ is correct.

3 • As a sinusoidal wave travels past a point on a taut string, the arrival time between successive crests is measured to be 0.20 s. Which of the following is true? (*a*) The wavelength of the wave is 5.0 m. (*b*) The frequency of the wave is 5.0 Hz. (*c*) The velocity of propagation of the wave is 5.0 m/s. (*d*) The wavelength of the wave is 0.20 m. (*e*) There is not enough information to justify any of these statements.

Determine the Concept The distance between successive crests is one wavelength and the time between successive crests is the period of the wave motion. Thus, T = 0.20 s and $f = 1/T = 5.0$ Hz. $\boxed{(b)}$ is correct.

4 • Two harmonic waves on identical strings differ only in amplitude. Wave A has an amplitude that is twice that of wave B's. How do the energies of these waves compare? (*a*) $E_A = E_B$. (*b*) $E_A = 2E_B$. (*c*) $E_A = 4E_B$. (*d*) There is not enough information to compare their energies.

Picture the Problem The average energy transmitted by a wave on a string is proportional to the square of its amplitude and is given by $(\Delta E)_{av} = \frac{1}{2}\mu\omega^2 A^2 \Delta x$ where A is the amplitude of the wave, μ is the linear density (mass per unit length)

of the string, ω is the angular frequency of the wave, and Δx is the length of the string.

Because the waves on the strings differ only in amplitude, the energy of the wave on string A is given by:

$$E_{\mathrm{A}} = cA_{\mathrm{A}}^2$$

Express the energy of the wave on string B:

$$E_{\mathrm{B}} = cA_{\mathrm{B}}^2$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{E_{\mathrm{A}}}{E_{\mathrm{B}}} = \frac{cA_{\mathrm{A}}^2}{cA_{\mathrm{B}}^2} = \left(\frac{A_{\mathrm{A}}}{A_{\mathrm{B}}}\right)^2$$

Because $A_{\mathrm{A}} = 2A_{\mathrm{B}}$:

$$\frac{E_{\mathrm{A}}}{E_{\mathrm{B}}} = \left(\frac{2A_{\mathrm{B}}}{A_{\mathrm{B}}}\right)^2 = 4 \Rightarrow \boxed{(c)} \text{ is correct.}$$

5 • [SSM] To keep all of the lengths of the treble strings (unwrapped steel wires) in a piano all about the same order of magnitude, wires of different linear mass densities are employed. Explain how this allows a piano manufacturer to use wires with lengths that are the same order of magnitude.

Determine the Concept The resonant (standing wave) frequencies on a string are inversely proportional to the square root of the linear density of the string $\left(f = \sqrt{T_{\mathrm{T}}/\mu}/\lambda\right)$. Thus extremely high frequencies (which might otherwise require very long strings) can be accommodated on relatively short strings if the strings are linearly less dense than the high frequency strings. High frequencies are not a problem as they use short strings anyway.

6 • Musical instruments produce sounds of widely varying frequencies. Which sounds waves have the longer wavelengths? (*a*) The lower frequencies. (*b*) The higher frequencies. (*c*) All frequencies have the same wavelength. (*d*) There is not enough information to compare the wavelengths of the different frequency sounds.

Determine the Concept Once the sound has been produced by a vibrating string, membrane, or air column, the speed with which it propagates is the product of its frequency and wavelength $(v = f\lambda)$. For a given medium and temperature, v is constant. Hence the wavelength and frequency for a given sound are inversely proportional and $\boxed{(a)}$ is correct.

7 • In Problem 6, which sound waves have the higher speeds? (*a*) The lower frequency sounds. (*b*) The higher frequency sounds. (*c*) All frequencies have the same wave speed. (*d*) There is not enough information to compare their speeds.

Determine the Concept Once the sound has been produced by a vibrating string, membrane, or air column, the wave speed with which it propagates depends on the properties of the medium in which it is propagating and is independent of the frequency and wavelength of the sound. $\boxed{(c)}$ is correct.

8 • Sound travels at 343 m/s in air and 1500 m/s in water. A sound of 256 Hz is made under water, but you hear the sound while walking along the side of the pool. In the air, the frequency is (*a*) the same, but the wavelength of the sound is shorter, (*b*) higher, but the wavelength of the sound stays the same, (*c*) lower, but the wavelength of the sound is longer, (*d*) lower, and the wavelength of the sound is shorter, (*e*) the same, and the wavelength of the sound stays the same.

Determine the Concept In any medium, the wavelength, frequency, and speed of a sound wave are related through $\lambda = v/f$. Because the frequency of a wave is determined by its source and is independent of the nature of the medium, if v is greater in water than in air, λ will be shorter in air than in water. $\boxed{(a)}$ is correct.

9 • While out on patrol, the battleship *Rodger Young* hits a mine, begins to burn, and ultimately explodes. Sailor Abel jumps into the water and begins swimming away from the doomed ship, while Sailor Baker gets into a life raft. Comparing their experiences later, Abel tells Baker, ″I was swimming underwater, and heard a big explosion from the ship. When I surfaced, I heard a second explosion. What do you think it could be?″ Baker says, ″I think it was your imagination—I only heard one explosion. ″ Explain why Baker only heard one explosion, while Abel heard two.

Determine the Concept There was only one explosion. Sound travels faster in water than air. Abel heard the sound wave in the water first, then, surfacing, heard the sound wave traveling through the air, which took longer to reach him.

10 • True or false: A 60-dB sound has twice the intensity of a 30-dB sound.

Picture the Problem The intensity level β, measured in decibels, is given by $\beta = (10\,\text{dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing.

Express the intensity level of the 60-dB sound:

$$60\,\text{dB} = (10\,\text{dB})\log\frac{I_{60}}{I_0} \Rightarrow I_{60} = 10^6 I_0$$

Express the intensity level of the 30-dB sound:

$$30\,\text{dB} = (10\,\text{dB})\log\frac{I_{30}}{I_0} \Rightarrow I_{30} = 10^3 I_0$$

Because $I_{60} = 10^3 I_{30}$, the statement is false.

11 • **[SSM]** At a given location, two harmonic sound waves have the same displacement amplitude, but the frequency of sound A is twice the frequency of sound B. How do their average energy densities compare? (*a*) The average energy density of A is twice the average energy density of B. (*b*) The average energy density of A is four times the average energy density of B. (*c*) The average energy density of A is 16 times the average energy density of B. (*d*) You cannot compare the average energy densities from the data given.

Determine the Concept The average energy density of a sound wave is given by $\eta_{\text{av}} = \frac{1}{2}\rho\omega^2 s_0^2$ where ρ is the average density of the medium, s_0 is the displacement amplitude of the molecules making up the medium, and ω is the angular frequency of the sound waves.

Express the average energy density of sound A:

$$\eta_{\text{av, A}} = \tfrac{1}{2}\rho_{\text{A}}\omega_{\text{A}}^2 s_{0,\text{A}}^2$$

The average energy density of sound B is given by:

$$\eta_{\text{av, B}} = \tfrac{1}{2}\rho_{\text{B}}\omega_{\text{B}}^2 s_{0,\text{B}}^2$$

Dividing the first of these equation by the second yields:

$$\frac{\eta_{\text{av, A}}}{\eta_{\text{av, B}}} = \frac{\tfrac{1}{2}\rho_{\text{A}}\omega_{\text{A}}^2 s_{0,\text{A}}^2}{\tfrac{1}{2}\rho_{\text{B}}\omega_{\text{B}}^2 s_{0,\text{B}}^2}$$

Because the sound waves are identical except for their frequencies:

$$\frac{\eta_{\text{av, A}}}{\eta_{\text{av, B}}} = \frac{\omega_{\text{A}}^2}{\omega_{\text{B}}^2} = \left(\frac{2\pi f_{\text{A}}}{2\pi f_{\text{B}}}\right)^2 = \left(\frac{f_{\text{A}}}{f_{\text{B}}}\right)^2$$

Because $f_{\text{A}} = 2f_{\text{B}}$:

$$\frac{\eta_{\text{av, A}}}{\eta_{\text{av, B}}} = \left(\frac{2f_{\text{B}}}{f_{\text{B}}}\right)^2 = 4 \Rightarrow \boxed{(b)} \text{ is correct.}$$

12 • At a given location, two harmonic sound waves have the same frequency but the amplitude of sound A is twice the amplitude of sound B. How do their average energy densities compare? (*a*) The average energy density of A is twice the average energy density of B. (*b*) The average energy density of A is four times the average energy density of B (*c*) The average energy density of A is 16

times the average energy density of B (*d*) You cannot compare the average energy densities from the data given.

Determine the Concept The average energy density of a sound wave is given by $\eta_{av} = \frac{1}{2}\rho\omega^2 s_0^2$ where ρ is the average density of the medium, s_0 is the displacement amplitude of the molecules making up the medium, and ω is the angular frequency of the sound waves.

Express the average energy density of sound A:

$$\eta_{av,A} = \tfrac{1}{2}\rho_A\omega_A^2 s_{0,A}^2$$

The average energy density of sound B is given by:

$$\eta_{av,B} = \tfrac{1}{2}\rho_B\omega_B^2 s_{0,B}^2$$

Dividing the first of these equation by the second yields:

$$\frac{\eta_{av,A}}{\eta_{av,B}} = \frac{\frac{1}{2}\rho_A\omega_A^2 s_{0,A}^2}{\frac{1}{2}\rho_B\omega_B^2 s_{0,B}^2}$$

Because the sound waves are identical except for their displacement amplitudes:

$$\frac{\eta_{av,A}}{\eta_{av,B}} = \frac{s_{0,A}^2}{s_{0,B}^2} = \left(\frac{s_{0,A}}{s_{0,B}}\right)^2$$

Because $s_{0,A} = 2s_{0,B}$

$$\frac{\eta_{av,A}}{\eta_{av,B}} = \left(\frac{2s_{0,B}}{s_{0,B}}\right)^2 = 4 \Rightarrow \boxed{(b)} \text{ is correct.}$$

13 • What is the ratio of the intensity of normal conversation to the sound intensity of a soft whisper (at a distance of 5.0 m)? (*a*) 10^3, (*b*) 2, (*c*) 10^{-3}, (*d*) 1/2. *Hint: See Table 15-1.*

Determine the Concept The problem is asking us for the ratio of the intensities corresponding to normal conversation and a soft whisper. Table 15-1 includes the quantities we need in order to find this ratio.

Use Table 15-1 to find the ratio of I/I_0, where I_0 is the threshold of hearing, for normal conversation:

$$\left(\frac{I}{I_0}\right)_{\substack{\text{normal}\\\text{conversation}}} = 10^6$$

Use Table 15-1 to find the ratio of I/I_0 for a soft whisper:

$$\left(\frac{I}{I_0}\right)_{\substack{\text{soft}\\\text{whisper}}} = 10^3$$

Dividing the first of these equation by the second yields:

$$\frac{\left(\frac{I}{I_0}\right)_{\substack{\text{normal}\\\text{conversation}}}}{\left(\frac{I}{I_0}\right)_{\substack{\text{soft}\\\text{whisper}}}}=\frac{10^6}{10^3}=10^3$$

$\boxed{(a)}$ is correct.

14 • What is the ratio of the intensity level of normal conversation to the sound intensity level of a soft whisper (at a distance of 5.0 m)? (*a*) 10^3, (*b*) 2, (*c*) 10^{-3}, (*d*) 1/2. *Hint: See Table 15-1.*

Determine the Concept The problem is asking us for the ratio of the sound intensity levels (decibel levels) corresponding to normal conversation and a soft whisper. Table 15-1 includes the quantities we need in order to find this ratio.

From Table 15-1, the sound intensity level corresponding to normal conversation is:

$$\beta_{\substack{\text{normal}\\\text{conversation}}}=60\text{ dB}$$

From Table 15-1, the sound intensity level corresponding to a soft whisper is:

$$\beta_{\substack{\text{soft}\\\text{whisper}}}=30\text{ dB}$$

Dividing the first of these equation by the second yields:

$$\frac{\beta_{\substack{\text{normal}\\\text{conversation}}}}{\beta_{\substack{\text{soft}\\\text{whisper}}}}=\frac{60\text{ dB}}{30\text{ dB}}=2$$

$\boxed{(b)}$ is correct.

15 • To increase the sound intensity level by 20 dB requires the sound intensity to increase by what factor? (*a*) 10, (*b*) 100, (*c*) 1000, (*d*) 2.

Determine the Concept The sound intensity level is given by $\beta=(10\text{ dB})\log(I/I_0)$ where I is the intensity of a given sound and I_0 is the intensity of the threshold of hearing.

The sound intensity level for a sound whose intensity is I_1 is given by:

$$\beta_1=(10\text{ dB})\log\left(\frac{I_1}{I_0}\right)$$

The sound intensity level for a sound whose intensity is I_2 is given by:

$$\beta_2=(10\text{ dB})\log\left(\frac{I_2}{I_0}\right)$$

Subtract the second equation from the first and simplify to obtain:

$$\beta_1 - \beta_2 = (10\text{ dB})\left(\log\left(\frac{I_1}{I_2}\right)\right)$$

Solving for I_1/I_2 yields:

$$\frac{I_1}{I_2} = 10^{\frac{\beta_1-\beta_2}{10\text{ dB}}}$$

For a 20-dB increase in the sound intensity level:

$$\frac{I_1}{I_2} = 10^{\frac{20\text{ dB}}{10\text{ dB}}} = 10^2 \Rightarrow \boxed{(b)} \text{ is correct.}$$

16 • You are using a hand-held sound level meter to measure the intensity level of the roars produced by a lion prowling in the high grass. To decrease the measured sound intensity level by 20 dB requires the lion move away from you until its distance from you has increased by what factor? (*a*) 10, (*b*) 100, (*c*) 1000, (*d*) You cannot tell the required distance from the data given.

Determine the Concept The sound intensity level is given by $\beta = (10\text{ dB})\log(I/I_0)$ where I is the intensity of a given sound and I_0 is the intensity of the threshold of hearing. The intensity of the a given sound varies with distance from its source according to $I = P_{\text{av}}/(4\pi r^2)$.

The sound intensity level for a sound whose intensity is I_1 is given by:

$$\beta_1 = (10\text{ dB})\log\left(\frac{I_1}{I_0}\right)$$

The sound intensity level for a sound whose intensity is I_2 is given by:

$$\beta_2 = (10\text{ dB})\log\left(\frac{I_2}{I_0}\right)$$

Subtract the second equation from the first and simplify to obtain:

$$\beta_1 - \beta_2 = (10\text{ dB})\left(\log\left(\frac{I_1}{I_2}\right)\right)$$

Solving for I_1/I_2 yields:

$$\frac{I_1}{I_2} = 10^{\frac{\beta_1-\beta_2}{10\text{ dB}}}$$

Letting r_1 be the lion's initial distance from you and r_2 be the lion's final distance from you, substitute for I_1 and I_2 and simplify to obtain:

$$\frac{\dfrac{P_{\text{av}}}{4\pi r_1^2}}{\dfrac{P_{\text{av}}}{4\pi r_2^2}} = \frac{r_2^2}{r_1^2} = 10^{\frac{\beta_1-\beta_2}{10\text{ dB}}} \Rightarrow \frac{r_2}{r_1} = \sqrt{10^{\frac{\beta_1-\beta_2}{10\text{ dB}}}}$$

For a 20-dB decrease in the sound intensity level:

$$\frac{r_2}{r_1} = \sqrt{10^{\frac{20\,\text{dB}}{10\,\text{dB}}}} = 10 \Rightarrow \boxed{(a)} \text{ is correct.}$$

17 • One end of a very light (but strong) thread is attached to an end of a thicker and denser cord. The other end of the thread is fastened to a sturdy post and you pull the other end of the cord so the thread and cord are taut. A pulse is sent down the thicker, denser cord. True or false:

(*a*) The pulse that is reflected back from the thread-cord attachment point is inverted compared to the initial incoming pulse.
(*b*) The pulse that continues past the thread-cord attachment point is not inverted compared to the initial incoming pulse.
(*c*) The pulse that continues past the thread-cord attachment point has an amplitude that is smaller than the pulse that is reflected.

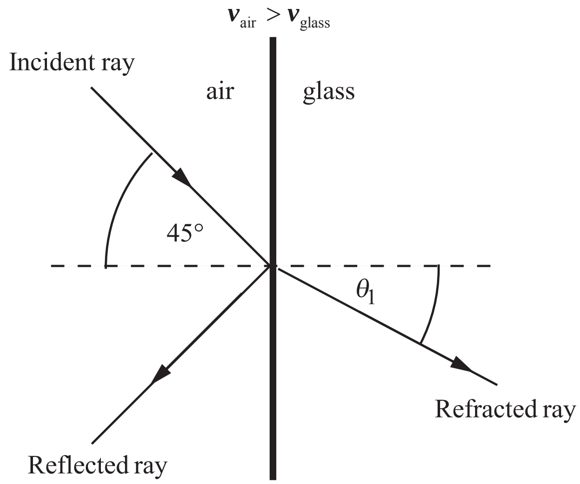
(*a*) False. Because the reflection medium (cord) in which the pulse travels initially has a greater linear density than the transmission medium (thread), there is no phase shift in the reflected pulse.

(*b*) True. Because the thread-cord attachment point of the media is more like a loose end than a fixed end, the pulse transmitted into the light thread is in phase with the incoming pulse in the thicker, denser cord.

(*c*) True. Because the string is attached to a thicker, denser cord, the reflected pulse behaves almost as though it was reflected from a fixed end and is, therefore, inverted. The pulse in the light thread is in phase with the incoming pulse in the thicker, denser cord. Because energy is conserved and there is some energy transmitted and some reflected, the transmitted wave cannot have an amplitude as large as the amplitude of the pulse in the thicker, denser cord.

18 • Light traveling in air strikes a glass surface at an incident angle of 45°. True or false: (*a*) The angle between the reflected light ray and the incident ray is 90°. (*b*) The angle between the reflected light ray and the refracted light ray is less than 90°.

Determine the Concept The ray diagram shows the relationship between the incident, reflected, and refracted rays.



(*a*) True. Because the angle of incidence is equal to the angle of reflection, the sum of these angles in this example is 90°. Note: this is a special case and is not generally true.

(*b*) False. Because light travels slower in glass than in air, the refracted ray makes an angle of less than 45° with the normal. Hence the angle it makes with the reflected ray is greater than 90°.

19 • **[SSM]** Sound waves in air encounter a 1.0-m wide door into a classroom. Due to the effects of diffraction, the sound of which frequency is least likely to be heard by all the students in the room, assuming the room is full? (*a*) 600 Hz, (*b*) 300 Hz, (*c*) 100 Hz, (*d*) All the sounds are equally likely to be heard in the room. (*e*) Diffraction depends on wavelength not frequency, so you cannot tell from the data given.

Determine the Concept If the wavelength is large relative to the door, the diffraction effects are large and the waves spread out as they pass through the door. Because we're interested in sounds that are least likely to be heard everywhere in the room, we want the wavelength to be short and the frequency to be high. Hence $\boxed{(a)}$ is correct.

20 • Microwave radiation in modern microwave ovens has a wavelength on the order of centimeters. Would you expect significant diffraction if this radiation was aimed at a 1.0-m wide door? Explain.

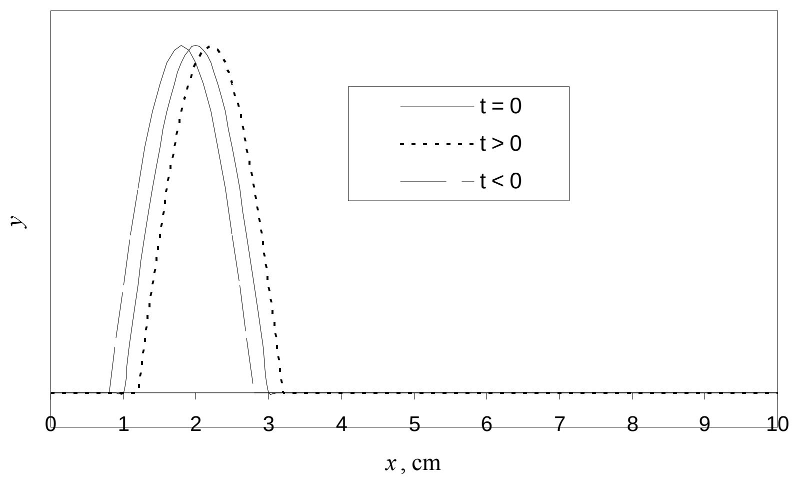
Determine the Concept No. Because the wavelength of the radiation is small relative to the door, the diffraction effects are small and the waves do not spread out significantly as they pass through the door.

21 •• [SSM] Stars often occur in pairs revolving around their common center of mass. If one of the stars is a black hole, it is invisible. Explain how the existence of such a black hole might be inferred by measuring the Doppler frequency shift of the light observed from the other, visible star.

Determine the Concept The light from the visible star will be shifted about its mean frequency periodically due to the relative approach toward and recession away from Earth as the star revolves about the common center of mass.

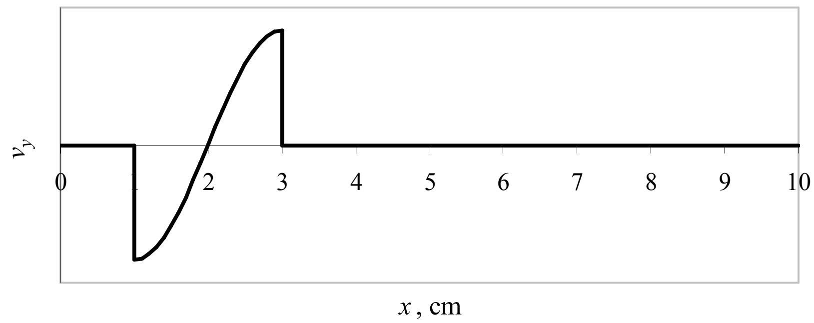
22 •• Figure 15-30 shows a wave pulse at time $t = 0$ moving to the right. (*a*) At this particular time, which segments of the string are moving up? (*b*) Which segments are moving down? (*c*) Is there any segment of the string at the pulse that is instantaneously at rest? Answer these questions by sketching the pulse at a slightly later time and a slightly earlier time to see how the segments of the string are moving.

Determine the Concept The graph shown below shows the pulse at an earlier time ($t < 0$) and later time ($t > 0$). (*a*) One can see that at $t = 0$, the portion of the string between 1 cm and 2 cm is moving down, (*b*) the portion between 2 cm and 3 cm is moving up, and (*c*) the string at $x = 2$ cm is instantaneously at rest.



23 •• Make a sketch of the velocity of each string segment versus position for the pulse shown in Figure 15-30.

Determine the Concept The velocity of the string at $t = 0$ is shown. Note that the velocity is negative for 1 cm < x < 2 cm and is positive for 2 cm < x < 3 cm.



24 •• An object of mass m hangs on a very light rope that is connected to the ceiling. You pluck the rope just above the object, and a wave pulse travels up to the ceiling and back. Compare the round-trip time for such a wave pulse to the round-trip time of a wave pulse on the same rope if an object of mass $9m$ is hung on the rope instead. (Assume the rope does not stretch, that is, the mass-to-ceiling distance is the same in each case.)

Determine the Concept If the mass providing the tension in the rope is increased by a factor of n, then the tension in the rope increases by the same factor and the speed of the pulse on the rope increases by a factor of $\sqrt{n}$ and the round trip time for the pulse is decreased by a factor of $1/\sqrt{n}$.

Let ℓ represent the distance the pulse travels. Then the time for the round trip is given by:

$$t = \frac{\ell}{v} \tag{1}$$

Express the speed of the wave when the object of mass m provides the tension in the rope:

$$v_m = \sqrt{\frac{F_{\mathrm{T},m}}{\mu}}$$

Express the speed of the wave when the object of mass $9m$ provides the tension in the rope:

$$v_{9m} = \sqrt{\frac{F_{\mathrm{T},9m}}{\mu}}$$

Substituting for v_{9m} in equation (1) yields:

$$t_{9m} = \frac{\ell}{\sqrt{\frac{F_{\mathrm{T},9m}}{\mu}}} = \ell\sqrt{\frac{\mu}{F_{\mathrm{T},9m}}} \tag{2}$$

Similarly, the travel time when the object whose mass is m is providing the tension is given by:

$$t_m = \frac{\ell}{\sqrt{\frac{F_{\mathrm{T},m}}{\mu}}} = \ell\sqrt{\frac{\mu}{F_{\mathrm{T},m}}} \tag{3}$$

Divide equation (2) by equation (3) and simplify to obtain:

$$\frac{t_{9m}}{t_m}=\sqrt{\frac{F_{\mathrm{T},m}}{F_{\mathrm{T},9m}}}$$

Because $F_{\mathrm{T},9m}=9F_{\mathrm{T},m}$:

$$\frac{t_{9m}}{t_m}=\sqrt{\frac{F_{\mathrm{T},m}}{9F_{\mathrm{T},m}}}=\tfrac{1}{3}\Rightarrow t_{9m}=\boxed{\tfrac{1}{3}t_m}$$

25 •• The explosion of a depth charge beneath the surface of the water is recorded by a helicopter hovering above its surface, as shown in Figure 15-31. Along which path—A, B, or C—will the sound wave take the least time to reach the helicopter? Explain why you chose the path you did.

Determine the Concept Path C. Because the wave speed is highest in the water, and more of path C is underwater than are paths A or B, the sound wave will spend the least time on path C.

26 •• Does a speed of Mach 2 at an altitude of 60,000 feet mean the same as a speed of Mach 2 near ground level? Explain clearly.

Determine the Concept No. The term Mach 2 means that the speed is twice the speed of sound at a given altitude. Because the speed of sound is lower at high altitudes than at ground level (due to lower density and colder temperature), Mach 2 means less than twice the speed of sound at sea level.

Estimation and Approximation

27 •• Many years ago, Olympic 100 m dashes were started by the sound from a starter's pistol, with the starter positioned several meters down the track, just on the inside of the track. (Today, the pistol that is used is often only a trigger, which is used to electronically activate speakers behind each sprinter's starting blocks. This method avoids the problem of one runner hearing sound before the other runners.) Estimate the time advantage the inside lane (relative to the runner at the outside lane of 8 runners) would have if all runners started when they heard the sound from the starter's pistol.

Picture the Problem Due to the differences in the distances from the starter to the inside- and outside-lane sprinters, the sound of the starting pistol took more time to reach the outside-lane sprinter than it did to reach the inside-lane sprinter.

Express the difference in time for the two sprinters in terms of the distances the sound must travel and the speed of sound:

$$\Delta t=t_{\substack{\text{ouside}\\\text{lane}}}-t_{\substack{\text{inside}\\\text{lane}}}=\frac{\ell_{\substack{\text{outside}\\\text{lane}}}}{v}-\frac{\ell_{\substack{\text{inside}\\\text{lane}}}}{v}$$

Assuming that the separation of the inside- and outside-lane sprinters is w:

$$\ell_{\substack{\text{outside}\\\text{lane}}} = \sqrt{\ell^2_{\substack{\text{inside}\\\text{lane}}} + w^2}$$

Substitute for $\ell_{\substack{\text{outside}\\\text{lane}}}$ to obtain:

$$\Delta t = \frac{\sqrt{\ell^2_{\substack{\text{inside}\\\text{lane}}} + w^2} - \ell_{\substack{\text{inside}\\\text{lane}}}}{v}$$

Assuming that the separation of the inside- and outside-lane sprinters is 7.0 m and that the starter is 5.0 m from the inside-lane sprinter yields:

$$\Delta t = \frac{\sqrt{(5.0\text{ m})^2 + (7.0\text{ m})^2} - 5.0\text{ m}}{343\text{ m/s}}$$
$$= \boxed{11\text{ ms}}$$

Remarks: Because a 100-m sprint is often decided by one or two hundredths of a second, this difference could be significant. This difference led to the invention of the electronic starter's sound.

28 •• Estimate the speed of the bullet as it passes through the helium balloon in Figure 15-32. *Hint: A protractor would be beneficial.*

Picture the Problem You can use a protractor to measure the angle of the shock cone and then estimate the speed of the bullet using $\sin\theta = v/u$. The speed of sound in helium at room temperature (293 K) is 977 m/s.

Relate the speed of the bullet u to the speed of sound v in helium and the angle of the shock cone θ:

$$\sin\theta = \frac{v}{u} \Rightarrow u = \frac{v}{\sin\theta}$$

Measuring θ yields:

$$\theta \approx 70°$$

Substitute numerical values and evaluate u:

$$u = \frac{977\text{ m/s}}{\sin 70°} = \boxed{1.0\text{ km/s}}$$

29 •• The new student townhouses at a local college are in the form of a semicircle half-enclosing the track field. To estimate the speed of sound in air, an ambitious physics student stood at the center of the semicircle and clapped his hands rhythmically at a frequency at which he could not hear the echo of the clap, because it reached him at the same time as his next clap. This frequency was about 2.5 claps/s. Once he established this frequency, he paced off the distance to the townhouses, which was 30 double strides. Assuming that the length of each stride is equal to half his height (5 ft 11 in), estimate the speed of sound in air using these data. How far off is your estimation from the commonly accepted value of 343 m/s?

Picture the Problem Let d be the distance to the townhouses. We can relate the speed of sound to the distance to the townhouses to the frequency of the clapping for which no echo is heard. 5 ft 11 in is equal to 1.8 m.

Relate the speed of sound to the distance it travels to the townhouses and back to the elapsed time:

$$v = \frac{2d}{\Delta t}$$

Express d in terms of the number of strides and distance covered per stride:

$$d = (30\,\text{strides})(1.8\,\text{m/stride}) = 54\,\text{m}$$

Relate the elapsed time Δt to the frequency f of the clapping:

$$\Delta t = \frac{1}{f} = \frac{1}{2.5\,\text{claps/s}} = 0.40\,\text{s}$$

Substitute numerical values and evaluate v:

$$v = \frac{2(54\,\text{m})}{0.40\,\text{s}} = 270\,\text{m/s} = \boxed{0.27\,\text{km/s}}$$

The percent difference between this result and 343 m/s is:

$$\%\,\text{diff} = \frac{343\,\text{m/s} - 270\,\text{m/s}}{343\,\text{m/s}} = \boxed{21\%}$$

Speed of Waves

30 • (a) The bulk modulus of water is 2.00×10^9 N/m^2. Use this value to find the speed of sound in water. (b) The speed of sound in mercury is 1410 m/s. What is the bulk modulus of mercury ($\rho = 13.6 \times 10^3$ kg/m^3)?

Picture the Problem The speed of sound in a fluid is given by $v = \sqrt{B/\rho}$ where B is the bulk modulus of the fluid and ρ is its density.

(a) Express the speed of sound in water in terms of its bulk modulus:

$$v = \sqrt{\frac{B}{\rho}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{2.00\times10^9\ \text{N/m}^2}{1.00\times10^3\ \text{kg/m}^3}} = 1.414\,\text{km/s}$$
$$= \boxed{1.41\,\text{km/s}}$$

(b) Solving $v = \sqrt{B/\rho}$ for B yields:

$$B = \rho v^2$$

Substitute numerical values and evaluate B:

$$B = (13.6\times10^3\ \text{kg/m}^3)(1410\,\text{m/s})^2$$
$$= \boxed{2.70\times10^{10}\ \text{N/m}^2}$$

31 • Calculate the speed of sound waves in hydrogen gas (M = 2.00 g/mol and γ = 1.40) at T = 300 K.

Picture the Problem The speed of sound in a gas is given by $v = \sqrt{\gamma RT/M}$ where R is the gas constant, T is the absolute temperature, M is the molecular mass of the gas, and γ is a constant that is characteristic of the particular molecular structure of the gas. Because hydrogen gas is diatomic, γ = 1.4.

Express the dependence of the speed of sound in hydrogen gas on the absolute temperature:

$$v = \sqrt{\frac{\gamma RT}{M}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{1.4(8.314\,\text{J/mol}\cdot\text{K})(300\,\text{K})}{2.00\times10^{-3}\,\text{kg/mol}}} = \boxed{1.32\,\text{km/s}}$$

32 • A 7.00-m-long string has a mass of 100 g and is under a tension of 900 N. What is the speed of a transverse wave pulse on this string?

Picture the Problem The speed of a transverse wave pulse on a string is given by $v = \sqrt{F_\text{T}/\mu}$ where F_T is the tension in the string, m is its mass, L is its length, and μ is its mass per unit length.

Express the dependence of the speed of the pulse on the tension in the string:

$v = \sqrt{\frac{F_\text{T}}{\mu}}$ where μ is the mass per unit length of the string.

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{900\,\text{N}}{\dfrac{0.100\,\text{kg}}{7.00\,\text{m}}}} = \boxed{251\,\text{m/s}}$$

33 •• **[SSM]** (*a*) Compute the derivative of the speed of a wave on a string with respect to the tension dv/dF_T, and show that the differentials dv and dF_T obey $dv/v = \frac{1}{2}dF_\text{T}/F_\text{T}$. (*b*) A wave moves with a speed of 300 m/s on a string that is under a tension of 500 N. Using the differential approximation, estimate how much the tension must be changed to increase the speed to 312 m/s. (*c*) Calculate ΔF_T exactly and compare it to the differential approximation result in Part (*b*). Assume that the string does not stretch with the increase in tension.

Picture the Problem (*a*) The speed of a transverse wave on a string is given by $v=\sqrt{F_T/\mu}$ where F_T is the tension in the wire and μ is its linear density. We can differentiate this expression with respect to F_T and then separate the variables to show that the differentials satisfy $dv/v=\frac{1}{2}dF_T/F_T$. (*b*) We'll approximate the differential quantities to determine by how much the tension must be changed to increase the speed of the wave to 312 m/s. (*c*) We can use $v=\sqrt{F_T/\mu}$ to obtain an exact expression for ΔF_T,

(*a*) Evaluate dv/dF_T:

$$\frac{dv}{dF}=\frac{d}{dF_T}\left[\sqrt{\frac{F_T}{\mu}}\right]=\frac{1}{2}\sqrt{\frac{1}{F_T\mu}}=\frac{1}{2}\cdot\frac{v}{F_T}$$

Separate the variables to obtain:

$$\frac{dv}{v}=\boxed{\frac{1}{2}\frac{dF_T}{F_T}}$$

(*b*) Solve the equation derived in Part (*a*) for dF_T:

$$dF_T=2F_T\frac{dv}{v}$$

Approximate dF_T with ΔF_T and dv with Δv to obtain:

$$\Delta F_T=2F_T\frac{\Delta v}{v}$$

Substitute numerical values and evaluate ΔF_T:

$$\Delta F_T=2(500\text{ N})\left(\frac{312\text{ m/s}-300\text{ m/s}}{300\text{ m/s}}\right)=\boxed{40\text{ N}}$$

(*c*) The exact value for $(\Delta F)_{\text{exact}}$ is given by:

$$(\Delta F)_{\text{exact}}=F_{T,2}-F_{T,1} \qquad (1)$$

Express the wave speeds for the two tensions:

$$v_1=\sqrt{\frac{F_{T,1}}{\mu}}\text{ and }v_2=\sqrt{\frac{F_{T,2}}{\mu}}$$

Dividing the second equation by the first and simplifying yields:

$$\frac{v_2}{v_1}=\frac{\sqrt{\dfrac{F_{T,2}}{\mu}}}{\sqrt{\dfrac{F_{T,1}}{\mu}}}=\sqrt{\frac{F_{T,2}}{F_{T,1}}}\Rightarrow F_{T,2}=F_{T,1}\left(\frac{v_2}{v_1}\right)^2$$

Substituting for $F_{T,2}$ in equation (1) yields:

$$\left(\Delta F_T\right)_{exact} = F_{F,1}\left(\frac{v_2}{v_1}\right)^2 - F_{T,1}$$
$$= F_{F,1}\left[\left(\frac{v_2}{v_1}\right)^2 - 1\right]$$

Substitute numerical values and evaluate $(\Delta F_T)_{exact}$:

$$\left(\Delta F_T\right)_{exact} = (500\ \text{N})\left[\left(\frac{312\ \text{m/s}}{300\ \text{m/s}}\right)^2 - 1\right]$$
$$= \boxed{40.8\ \text{N}}$$

The percent error between the exact and approximate values for ΔF_T is:

$$\frac{\left(\Delta F_T\right)_{exact} - \Delta F_T}{\left(\Delta F_T\right)_{exact}} = \frac{40.8\ \text{N} - 40.0\ \text{N}}{40.8\ \text{N}}$$
$$\approx \boxed{2\%}$$

34 •• (*a*) Compute the derivative of the speed of sound in air with respect to the absolute temperature, and show that the differentials dv and dT obey $dv/v = \frac{1}{2}dT/T$. (*b*) Use this result to estimate the percentage change in the speed of sound when the temperature changes from 0 to 27°C. (*c*) If the speed of sound is 331 m/s at 0°C, estimate its value at 27°C using the differential approximation. (*d*) How does this approximation compare with the result of an exact calculation?

Picture the Problem The speed of sound in a gas is given by $v = \sqrt{\gamma RT/M}$ where R is the gas constant, T is the absolute temperature, M is the molecular mass of the gas, and γ is a constant that is characteristic of the particular molecular structure of the gas. We can differentiate this expression with respect to T and then separate the variables to show that the differentials satisfy $dv/v = \frac{1}{2}dT/T$. We'll approximate the differential quantities to estimate the percentage change in the speed of sound when the temperature increases from 0 to 27°C. Lacking information regarding the nature of the gas, we can express the ratio of the speeds of sound at 300 K and 273 K to obtain an expression that involves just the temperatures.

(*a*) Evaluate dv/dT:

$$\frac{dv}{dT} = \frac{d}{dT}\left[\sqrt{\frac{\gamma RT}{M}}\right] = \frac{1}{2}\sqrt{\frac{M}{\gamma RT}}\left(\frac{\gamma R}{M}\right)$$
$$= \frac{1}{2}\frac{v}{T}$$

Separate the variables to obtain:

$$\frac{dv}{v}=\boxed{\frac{1}{2}\frac{dT}{T}}$$

(*b*) Approximate dT with ΔT and dv with Δv and substitute numerical values to obtain:

$$\frac{\Delta v}{v}=\frac{1}{2}\left(\frac{300\text{ K}-273\text{ K}}{273\text{ K}}\right)=\boxed{5.0\%}$$

(*c*) Using a differential approximation, approximate the speed of sound at 300 K:

$$v_{300\text{ K}}\approx v_{273\text{ K}}+v_{273\text{ K}}\frac{\Delta v}{v}$$
$$=v_{273\text{ K}}\left(1+\frac{\Delta v}{v}\right)$$

Substitute numerical values and evaluate $v_{300\text{ K}}$:

$$v_{300\text{ K}}=(331\text{ m/s})(1+0.0495)$$
$$=\boxed{347\text{ m/s}}$$

(*d*) Use $v=\sqrt{\gamma RT/M}$ to express the speed of sound at 300 K:

$$v_{300\text{ K}}=\sqrt{\frac{\gamma R(300\text{ K})}{M}}$$

Use $v=\sqrt{\gamma RT/M}$ to express the speed of sound at 273 K:

$$v_{273\text{ K}}=\sqrt{\frac{\gamma R(273\text{ K})}{M}}$$

Divide the first of these equations by the second and solve for and evaluate $v_{300\text{ K}}$:

$$\frac{v_{300\text{ K}}}{v_{273\text{ K}}}=\frac{\sqrt{\frac{\gamma R(300\text{ K})}{M}}}{\sqrt{\frac{\gamma R(273\text{ K})}{M}}}=\sqrt{\frac{300}{273}}$$

and

$$v_{300\text{ K}}=(331\text{ m/s})\sqrt{\frac{300}{273}}=\boxed{347\text{ m/s}}$$

Note that these two results agree to three significant figures.

35 ••• Derive a convenient formula for the speed of sound in air at temperature t in Celsius degrees. Begin by writing the temperature as $T = T_0 + \Delta T$, where $T_0 = 273$ K corresponds to 0°C and $\Delta T = t$, the Celsius temperature. The speed of sound is a function of T, $v(T)$. To a first-order approximation, you can write $v(T)\approx v(T_0)+(dv/dT)_{T_0}\,\Delta T$, where $(dv/\,dT)_{T_0}$ is the derivative evaluated at $T = T_0$. Compute this derivative, and show that the result leads to $v=(331\text{ m/s})\left(1+\dfrac{t}{2T_0}\right)=(331+0.606t)$ m/s.

Picture the Problem We can use the approximate expression for $v(T)$ given in the problem statement and the result of Problem 34 to show that $v = (331 + 0.606t)\,\text{m/s}$.

The speed of sound as a function of T is given by:

$$v(T) \approx v(T_0) + \left(\frac{dv}{dT}\right)_{T_0} \Delta T \qquad (1)$$

From Problem 44, dv/dT is given by:

$$\frac{dv}{dt} = \frac{1}{2}\frac{v(T)}{T}$$

Evaluating $\left.\frac{dv}{dT}\right]_{T=T_0}$ yields:

$$\left.\frac{dv}{dT}\right]_{T=T_0} = \frac{1}{2}\frac{v(T_0)}{T_0} \qquad (2)$$

Substitute equation (2) in equation (1) and simplify to obtain:

$$v(T) \approx v(T_0) + \left(\frac{1}{2}\frac{v(T_0)}{T_0}\right)\Delta T = v(T_0)\left(1 + \frac{\Delta T}{2T_0}\right)$$

For T_0 = 273° K, $v(T_0) = 331\,\text{m/s}$, and $\Delta T = t$:

$$v = (331\,\text{m/s})\left(1 + \frac{t}{2(273\,\text{K})}\right) = \boxed{(331 + 0.606t)\,\text{m/s}}$$

The Wave Equation

36 • Show explicitly that the following functions satisfy the wave equation $\frac{\partial^2 y}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y}{\partial t^2}$: (*a*) $y(x,t) = k(x + vt)^3$, (*b*) $y(x, t) = Ae^{ik(x-vt)}$, where A and k are constants and $i = \sqrt{-1}$, and (*c*) $y(x,t) = \ln k(x - vt)$.

Picture the Problem To show that each of the functions satisfies the wave equation, we'll need to find their first and second derivatives with respect to x and t and then substitute these derivatives in the wave equation.

(*a*) Find the first two spatial derivatives of $y(x,t) = k(x + vt)^3$:

$$\frac{\partial y}{\partial x} = 3k(x + vt)^2$$

and

$$\frac{\partial^2 y}{\partial x^2} = 6k(x + vt) \qquad (1)$$

Find the first two temporal derivatives of $y(x,t)=k(x+vt)^3$:

$$\frac{\partial y}{\partial t}=3kv(x+vt)^2$$

and

$$\frac{\partial^2 y}{\partial t^2}=6kv^2(x+vt) \qquad (2)$$

Express the ratio of equation (1) to equation (2):

$$\frac{\dfrac{\partial^2 y}{\partial x^2}}{\dfrac{\partial^2 y}{\partial t^2}}=\frac{6k(x+vt)}{6kv^2(x+vt)}=\boxed{\frac{1}{v^2}}$$

confirming that $y(x,t)=k(x+vt)^3$ satisfies the general wave equation.

(*b*) Find the first two spatial derivatives of $y(x,t)=Ae^{ik(x-vt)}$:

$$\frac{\partial y}{\partial x}=ikAe^{ik(x-vt)},\ \frac{\partial^2 y}{\partial x^2}=i^2k^2Ae^{ik(x-vt)}$$

or

$$\frac{\partial^2 y}{\partial x^2}=-k^2Ae^{ik(x-vt)} \qquad (3)$$

Find the first two temporal derivatives of $y(x,t)=Ae^{ik(x-vt)}$:

$$\frac{\partial y}{\partial t}=-ikvAe^{ik(x-vt)},$$

$$\frac{\partial^2 y}{\partial t^2}=i^2k^2v^2Ae^{ik(x-vt)}$$

or

$$\frac{\partial^2 y}{\partial t^2}=-k^2v^2Ae^{ik(x-vt)} \qquad (4)$$

Express the ratio of equation (3) to equation (4):

$$\frac{\dfrac{\partial^2 y}{\partial x^2}}{\dfrac{\partial^2 y}{\partial t^2}}=\frac{-k^2Ae^{ik(x-vt)}}{-k^2v^2Ae^{ik(x-vt)}}=\boxed{\frac{1}{v^2}}$$

confirming that $y(x,t)=Ae^{ik(x-vt)}$ satisfies the general wave equation.

(*c*) Find the first two spatial derivatives of $y(x,\,t)=\ln k(x-vt)$:

$$\frac{\partial y}{\partial x}=\frac{k}{x-vt}$$

and

$$\frac{\partial^2 y}{\partial x^2}=-\frac{k^2}{(x-vt)^2} \qquad (5)$$

Find the first two temporal derivatives of $y(x, t) = \ln k(x - vt)$:

$$\frac{\partial y}{\partial t} = -\frac{vk}{x - vt}$$

and

$$\frac{\partial^2 y}{\partial t^2} = -\frac{v^2 k^2}{(x - vt)^2} \qquad (6)$$

Express the ratio of equation (5) to equation (6):

$$\frac{\dfrac{\partial^2 y}{\partial x^2}}{\dfrac{\partial^2 y}{\partial t^2}} = \frac{-\dfrac{k^2}{(x - vt)^2}}{-\dfrac{v^2 k^2}{(x - vt)^2}} = \boxed{\frac{1}{v^2}}$$

confirming that $y(x, t) = \ln k(x - vt)$ satisfies the general wave equation.

37 • Show that the function $y = A \sin kx \cos \omega t$ satisfies the wave equation.

Picture the Problem The wave equation is $\frac{\partial^2 y}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y}{\partial t^2}$. To show that $y = A \sin kx \cos \omega t$ satisfies this equation, we'll need to find the first and second derivatives of y with respect to x and t and then substitute these derivatives in the wave equation.

Find the first two spatial derivatives of $y = A \sin kx \cos \omega t$:

$$\frac{\partial y}{\partial x} = Ak \cos kx \cos \omega t$$

and

$$\frac{\partial^2 y}{\partial x^2} = -Ak^2 \sin kx \cos \omega t \qquad (1)$$

Find the first two temporal derivatives of $y = A \sin kx \cos \omega t$:

$$\frac{\partial y}{\partial t} = -\omega A \sin kx \sin \omega t$$

and

$$\frac{\partial^2 y}{\partial t^2} = -\omega^2 A \sin kx \cos \omega t \qquad (2)$$

Express the ratio of equation (1) to equation (2):

$$\frac{\dfrac{\partial^2 y}{\partial x^2}}{\dfrac{\partial^2 y}{\partial t^2}} = \frac{-Ak^2 \sin kx \cos \omega t}{-A\omega^2 \sin kx \cos \omega t} = \frac{k^2}{\omega^2}$$

$$= \boxed{\frac{1}{v^2}}$$

confirming that $y = A \sin kx \cos \omega t$ satisfies the general wave equation.

Harmonic Waves on a String

38 • One end of a string 6.0 m long is moved up and down with simple harmonic motion at a frequency of 60 Hz. If the wave crests travel the length of the string in 0.50 s, find the wavelength of the waves on the string.

Picture the Problem We can find the wavelength of the waves on the string using the relationship $v = f\lambda$.

Express the wavelength of the waves:

$$f\lambda = v \Rightarrow \lambda = \frac{v}{f}$$

The speed of the wave is equal to the distance divided by the time:

$$v = \frac{\Delta x}{\Delta t} = \frac{6.0\,\text{m}}{0.50\,\text{s}} = 12\,\text{m/s}$$

Substitute numerical values to obtain:

$$\lambda = \frac{12\,\text{m/s}}{60\,\text{s}^{-1}} = \boxed{20\,\text{cm}}$$

39 • **[SSM]** A harmonic wave on a string with a mass per unit length of 0.050 kg/m and a tension of 80 N, has an amplitude of 5.0 cm. Each point on the string moves with simple harmonic motion at a frequency of 10 Hz. What is the power carried by the wave propagating along the string?

Picture the Problem The average power propagated along the string by a harmonic wave is $P_{\text{av}} = \frac{1}{2}\mu\omega^2 A^2 v,$ where v is the speed of the wave, and $\mu,$ $\omega,$ and A are the linear density of the string, the angular frequency of the wave, and the amplitude of the wave, respectively.

Express and evaluate the power propagated along the string:

$$P_{\text{av}} = \frac{1}{2}\mu\omega^2 A^2 v$$

The speed of the wave on the string is given by:

$$v=\sqrt{\frac{F_{\mathrm{T}}}{\mu}}$$

Substitute for v and simplify to obtain:

$$P_{\mathrm{av}}=\tfrac{1}{2}\mu\omega^2A^2\sqrt{\frac{F_{\mathrm{T}}}{\mu}}=\tfrac{1}{2}(2\pi f)^2A^2\sqrt{F_{\mathrm{T}}\mu}$$
$$=2(\pi fA)^2\sqrt{F_{\mathrm{T}}\mu}$$

Substitute numerical values and evaluate P_{av}:

$$P_{\mathrm{av}}=2\left[\pi\left(10\,\mathrm{s}^{-1}\right)(0.050\,\mathrm{m})\right]^2\sqrt{(80\,\mathrm{N})(0.050\,\mathrm{kg/m})}=\boxed{9.9\,\mathrm{W}}$$

40 • A 2.00-m-long rope has a mass of 0.100 kg. The tension is 60.0 N. An oscillator at one end sends a harmonic wave with an amplitude of 1.00 cm down the rope. The other end of the rope is terminated so that all of the energy of the wave is absorbed and none is reflected. What is the frequency of the oscillator if the power transmitted is 100 W?

Picture the Problem The average power propagated along the rope by a harmonic wave is $P_{\mathrm{av}}=\tfrac{1}{2}\mu\omega^2A^2v,$ where v is the velocity of the wave, and μ, ω, and A are the linear density of the string, the angular frequency of the wave, and the amplitude of the wave, respectively.

Rewrite the power equation in terms of the frequency of the wave:

$$P_{\mathrm{av}}=\tfrac{1}{2}\mu\omega^2A^2v=2\pi^2\mu f^2A^2v$$

Solve for the frequency and simplify to obtain:

$$f=\sqrt{\frac{P_{\mathrm{av}}}{2\pi^2\mu A^2v}}=\frac{1}{2\pi A}\sqrt{\frac{2P_{\mathrm{av}}}{\mu v}}$$

The wave speed is given by:

$$v=\sqrt{\frac{F_{\mathrm{T}}}{\mu}}$$

Substitute for v and simplify to obtain:

$$f=\frac{1}{2\pi A}\sqrt{\frac{2P_{\mathrm{av}}}{\mu\sqrt{\frac{F_{\mathrm{T}}}{\mu}}}}=\frac{1}{2\pi A}\sqrt{\frac{2P_{\mathrm{av}}}{\sqrt{\mu F_{\mathrm{T}}}}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi(0.0100\text{ m})}\sqrt{\frac{2(100\text{ W})}{\sqrt{\left(\frac{0.100\text{ kg}}{2.00\text{ m}}\right)(60.0\text{ N})}}} = \boxed{171\text{ Hz}}$$

41 •• The wave function for a harmonic wave on a string is $y(x, t) = (1.00\text{ mm})\sin(62.8\text{ m}^{-1}x + 314\text{ s}^{-1}t)$. (*a*) In what direction does this wave travel, and what is the wave's speed? (*b*) Find the wavelength, frequency, and period of this wave. (*c*) What is the maximum speed of any point on the string?

Picture the Problem $y(x,t) = A\sin(kx - \omega t)$ describes a wave traveling in the $+x$ direction. For a wave traveling in the $-x$ direction, we have $y(x,t) = A\sin(kx + \omega t)$. We can determine A, k, and ω by examination of the wave function. The wavelength, frequency, and period of the wave can, in turn, be determined from k and ω.

(*a*) Because the sign between the kx and ωt terms is positive, the wave is traveling in the $-x$ direction.

The speed of the wave is:

$$v = \frac{\omega}{k} = \frac{314\text{ s}^{-1}}{62.8\text{ m}^{-1}} = \boxed{5.00\text{ m/s}}$$

(*b*) The coefficient of x is k and:

$$k = \frac{2\pi}{\lambda} \Rightarrow \lambda = \frac{2\pi}{k}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{2\pi}{62.8\text{ m}^{-1}} = \boxed{10.0\text{ cm}}$$

The coefficient of t is ω and:

$$f = \frac{\omega}{2\pi} = \frac{314\text{ s}^{-1}}{2\pi} = \boxed{50.0\text{ Hz}}$$

The period of the wave motion is the reciprocal of its frequency:

$$T = \frac{1}{f} = \frac{1}{50.0\text{ s}^{-1}} = \boxed{0.0200\text{ s}}$$

(*c*) Express and evaluate the maximum speed of any string segment:

$$v_{max} = A\omega = (1.00\text{ mm})(314\text{ rad/s}) = \boxed{0.314\text{ m/s}}$$

42 •• A harmonic wave on a string with a frequency of 80 Hz and an amplitude of 0.025 m travels in the $+x$ direction with a speed of 12 m/s. (*a*) Write a suitable wave function for this wave. (*b*) Find the maximum speed of a point on the string. (*c*) Find the maximum acceleration of a point on the string.

Picture the Problem $y(x,t)=A\sin(kx-\omega t)$ describes a wave traveling in the $+x$ direction. We can find ω and k from the data included in the problem statement and substitute in the general equation. The maximum speed of a point on the string can be found from $v_{\max}=A\omega$ and the maximum acceleration from $a_{\max}=A\omega^2$.

(*a*) Express the general form of the equation of a harmonic wave traveling to the right:

$$y(x,t)=A\sin(kx-\omega t)$$

Evaluate ω:

$$\omega=2\pi f=2\pi\left(80\,\mathrm{s}^{-1}\right)=503\,\mathrm{s}^{-1}$$
$$=5.0\times10^{2}\,\mathrm{s}^{-1}$$

Determine k:

$$k=\frac{\omega}{v}=\frac{503\,\mathrm{s}^{-1}}{12\,\mathrm{m/s}}=42\,\mathrm{m}^{-1}$$

Substitute to obtain: $y(x,t)=\boxed{(0.025\,\mathrm{m})\sin\left[\left(42\,\mathrm{m}^{-1}\right)x-\left(5.0\times10^{2}\,\mathrm{s}^{-1}\right)t\right]}$

(*b*) The maximum speed of a point on the string is:

$$v_{\max}=A\omega=(0.025\,\mathrm{m})\left(503\,\mathrm{s}^{-1}\right)$$
$$=\boxed{13\,\mathrm{m/s}}$$

(*c*) Express the maximum acceleration of a point on the string:

$$a_{\max}=A\omega^2$$

Substitute numerical values and evaluate $a_{\max}$:

$$a_{\max}=(0.025\,\mathrm{m})\left(503\,\mathrm{s}^{-1}\right)^2=\boxed{6.3\,\mathrm{km/s^2}}$$

43 •• A 200-Hz harmonic wave with an amplitude equal to 1.2 cm moves along a 40-m-long string that has a mass of 0.120 kg and a tension of 50 N. (*a*) What is the average total energy of the waves on a 20-m-long segment of string? (*b*) What is the power transmitted past a given point on the string?

Picture the Problem The average power propagated along the string is $P_{\mathrm{av}}=\frac{1}{2}\mu\omega^2A^2v.$ The average energy on a segment of length L is the average power multiplied by the time for the wave to travel the distance L

(*a*) Express the power transmitted past a given point on the string. The average energy passing a point in time *t* is the average power multiplied by the time:

$$P_{av} = \tfrac{1}{2}\mu\omega^2 A^2 v$$

and

$$E_{av} = P_{av} t$$

The time for the wave to travel the length L is L/v:

$$t = \frac{L}{v}$$

Combine the previous steps and solve for the average energy on the string:

$$E_{av} = \tfrac{1}{2}\mu v\omega^2 A^2 \frac{L}{v} = \tfrac{1}{2}\mu L\omega^2 A^2 = \tfrac{1}{2}\mu L(2\pi f)^2 A^2 = 2\pi^2\mu L f^2 A^2$$

Substitute numerical values and evaluate E_{av}:

$$E_{av} = 2\pi^2\left(\frac{0.120\,\text{kg}}{40\,\text{m}}\right)\left(200\,\text{s}^{-1}\right)^2(20\,\text{m})(0.012\,\text{m})^2 = \boxed{6.8\,\text{J}}$$

(*b*) Express P_{av}:

$$P_{av} = \tfrac{1}{2}\mu v\omega^2 A^2$$

To calculate P_{av} we need an expression for the wave speed v:

$$v = \sqrt{\frac{F_T}{\mu}}$$

Substitute for v to obtain:

$$P_{av} = \tfrac{1}{2}\mu(2\pi f)^2 A^2\sqrt{\frac{F_T}{\mu}} = 2\pi^2\mu f^2 A^2\sqrt{\frac{F_T}{\mu}}$$

Substitute numerical values and evaluate P_{av}:

$$P_{av} = 2\pi^2\left(\frac{0.060\,\text{kg}}{20\,\text{m}}\right)\left(200\,\text{s}^{-1}\right)^2(0.012\,\text{m})^2\sqrt{\frac{50\,\text{N}}{\frac{0.060\,\text{kg}}{20\,\text{m}}}} = \boxed{44\,\text{W}}$$

44 •• On a real string, some of the energy of the wave dissipates as the wave travels down the string. Such a situation can be described by a wave function whose amplitude $A(x)$ depends on x: $y = A(x)\sin(kx - \omega t)$ where $A(x) = (A_0 e^{-bx})$. What is the power transported by the wave as a function of x, where $x > 0$?

Picture the Problem The power propagated along the string by a harmonic wave is $P = \frac{1}{2}\mu\omega^2 A^2 v$ where v is the velocity of the wave, and μ, ω, and A are the linear density of the string, the angular frequency of the wave, and the amplitude of the wave, respectively.

Express the power associated with the wave at the origin:

$$P = \frac{1}{2}\mu\omega^2 A^2 v \quad (1)$$

Express the amplitude of the wave at x:

$$A(x) = A_0 e^{-bx}$$

Substitute in equation (1) to obtain:

$$P(x) = \frac{1}{2}\mu\omega^2\left(A_0 e^{-bx}\right)^2 v = \boxed{\frac{1}{2}\mu\omega^2 A_0^2 v e^{-2bx}}$$

45 •• **[SSM]** Power is to be transmitted along a taut string by means of transverse harmonic waves. The wave speed is 10 m/s and the linear mass density of the string is 0.010 kg/m. The power source oscillates with an amplitude of 0.50 mm. (*a*) What average power is transmitted along the string if the frequency is 400 Hz? (*b*) The power transmitted can be increased by increasing the tension in the string, the frequency of the source, or the amplitude of the waves. By how much would each of these quantities have to increase to cause an increase in power by a factor of 100 if it is the only quantity changed?

Picture the Problem The average power propagated along a string by a harmonic wave is $P_{av} = \frac{1}{2}\mu\omega^2 A^2 v$ where v is the speed of the wave, and μ, ω, and A are the linear density of the string, the angular frequency of the wave, and the amplitude of the wave, respectively.

(*a*) Express the average power transmitted along the string:

$$P_{av} = \frac{1}{2}\mu\omega^2 A^2 v = 2\pi^2 \mu f^2 A^2 v$$

Substitute numerical values and evaluate P_{av}:

$$P_{av} = 2\pi^2 (0.010\,\text{kg/m})(400\,\text{s}^{-1})^2 \times (0.50\times10^{-3}\,\text{m})^2 (10\,\text{m/s}) = \boxed{79\,\text{mW}}$$

(*b*) Because $P_{av} \propto f^2$, increasing the frequency by a factor of 10 would increase the power by a factor of 100.

Because $P_{av} \propto A^2$, increasing the amplitude by a factor of 10 would increase the power by a factor of 100.

Because $P_{av} \propto v$ and $v \propto \sqrt{F}$, increasing the tension by a factor of 10^4 would increase v by a factor of 100 and the power by a factor of 100.

46 ••• Two very long strings are tied together at the point $x = 0$. In the region $x < 0$, the wave speed is v_1, while in the region $x > 0$, the speed is v_2. A sinusoidal wave is incident on the knot from the left ($x < 0$); part of the wave is reflected and part is transmitted. For $x < 0$, the displacement of the wave is describabed by $y(x,t) = A \sin(k_1x - \omega t) + B \sin(k_1x + \omega t)$, while for $x > 0$, $y(x,t) = C \sin(k_2x - \omega t)$, where $\omega/k_1 = v_1$ and $\omega/k_2 = v_2$. (*a*) If we assume that both the wave function y and its first spatial derivative $\partial y/\partial x$ must be continuous at $x = 0$, show that $C/A = 2v_2/(v_1 + v_2)$, and that $B/A = (v_1 - v_2)/(v_1 + v_2)$. (*b*) Show that $B^2 + (v_1/v_2)C^2 = A^2$.

Picture the Problem We can use the assumption that both the wave function and its first spatial derivative are continuous at $x = 0$ to establish equations relating A, B, C, k_1, and k_2. Then, we can solve these simultaneous equations to obtain expressions for B and C in terms of A, v_1, and v_2.

(*a*) Let $y_1(x, t)$ represent the wave function in the region $x < 0$, and $y_2(x, t)$ represent the wave function in the region $x > 0$. Express the continuity of the two wave functions at $x = 0$:

$$y_1(0,t) = y_2(0,t)$$
and
$$A\sin[k_1(0) - \omega t] + B\sin[k_1(0) + \omega t] = C\sin[k_2(0) - \omega t]$$
or
$$A\sin(-\omega t) + B\sin\omega t = C\sin(-\omega t)$$

Because the sine function is odd; that is, $\sin(-\theta) = -\sin\theta$:

$$-A\sin\omega t + B\sin\omega t = -C\sin\omega t$$
and
$$A - B = C \qquad (1)$$

Differentiate the wave functions with respect to x to obtain:

$$\frac{\partial y_1}{\partial x} = Ak_1\cos(k_1x - \omega t) + Bk_1\cos(k_1x + \omega t)$$
and
$$\frac{\partial y_2}{\partial x} = Ck_2\cos(k_2x - \omega t)$$

Express the continuity of the slopes of the two wave functions at $x = 0$:

$$\left.\frac{\partial y_1}{\partial x}\right|_{x=0} = \left.\frac{\partial y_2}{\partial x}\right|_{x=0}$$

and

$$Ak_1\cos[k_1(0)-\omega t]+Bk_1\cos[k_1(0)+\omega t] = Ck_2\cos[k_2(0)-\omega t]$$

or

$$Ak_1\cos(-\omega t)+Bk_1\cos\omega t = Ck_2\cos(-\omega t)$$

Because the cosine function is even; that is, $\cos(-\theta)=\cos\theta$:

$$Ak_1\cos\omega t + Bk_1\cos\omega t = Ck_2\cos\omega t$$

and

$$k_1A + k_1B = k_2C \qquad (2)$$

Multiply equation (1) by k_1 and add it to equation (2) to obtain:

$$2k_1A = (k_1 + k_2)C$$

Solving for C yields:

$$C = \frac{2k_1}{k_1+k_2}A = \frac{2}{1+k_2/k_1}A$$

Solve for C/A and substitute ω/v_1 for k_1 and ω/v_2 for k_2 to obtain:

$$\frac{C}{A} = \frac{2}{1+k_2/k_1} = \frac{2}{1+v_1/v_2} = \boxed{\frac{2v_2}{v_1+v_2}}$$

Substitute in equation (1) to obtain:

$$A - B = \left(\frac{2v_2}{v_2+v_1}\right)A$$

Solving for B/A yields:

$$\frac{B}{A} = \boxed{\frac{v_1-v_2}{v_1+v_2}}$$

(b) We wish to show that

$$B^2 + (v_1/v_2)C^2 = A^2$$

Use the results of (a) to obtain the expressions $B = -[(1 - \alpha)/(1 + \alpha)]\,A$ and $C = 2A/(1 + \alpha)$, where $\alpha = v_1/v_2$.

Substitute these expressions into

$$B^2 + (v_1/v_2)C^2 = A^2$$

and check to see if the resulting equation is an identity:

$$B^2 + \frac{v_1}{v_2}C^2 = A^2$$

$$\left(\frac{1-\alpha}{1+\alpha}\right)^2 A^2 + \alpha\left(\frac{2}{1+\alpha}\right)^2 A^2 = A^2$$

$$\left(\frac{1-\alpha}{1+\alpha}\right)^2 + \alpha\left(\frac{2}{1+\alpha}\right)^2 = 1$$

$$\frac{(1-\alpha)^2 + 4\alpha}{(1+\alpha)^2} = 1$$

$$\frac{1-2\alpha+\alpha^2+4\alpha}{(1+\alpha)^2} = 1$$

$$\frac{1+2\alpha+\alpha^2}{(1+\alpha)^2} = 1$$

$$\frac{(1+\alpha)^2}{(1+\alpha)^2} = 1$$

$$1 = 1$$

The equation is an identity: Therefore, $\boxed{B^2 + \frac{v_1}{v_2}C^2 = A^2}$

Remarks: Our result in (*a*) can be checked by considering the limit of *B*/*A* as $v_2/v_1 \to 0$. This limit gives *B*/*A* = +1, telling us that the transmitted wave has zero amplitude and the incident and reflected waves superpose to give a standing wave with a node at *x* = 0.

Harmonic Sound Waves

47 • A sound wave in air produces a pressure variation given by $p(x,t) = 0.75\cos\frac{\pi}{2}(x - 343t)$, where p is in pascals, x is in meters, and t is in seconds. Find (a) the pressure amplitude, (b) the wavelength, (c) the frequency, and (d) the wave speed.

Picture the Problem The pressure variation is of the form $p(x,t) = p_0\cos k(x - vt)$ where k is the wave number, p_0 is the pressure amplitude, and v is the wave speed. We can find λ from k and f from ω and k.

(a) By inspection of the equation: $p_0 = \boxed{0.75\,\text{Pa}}$

(b) Because $k=\dfrac{2\pi}{\lambda}=\dfrac{\pi}{2}$: $\lambda=\boxed{4.00\,\text{m}}$

(c) Solve $v=\dfrac{\omega}{k}=\dfrac{2\pi f}{k}$ for f to obtain: $f=\dfrac{kv}{2\pi}$

Substitute numerical values and evaluate f:

$$f=\frac{\frac{\pi}{2}(343\,\text{m/s})}{2\pi}=\boxed{85.8\,\text{Hz}}$$

(d) By inspection of the equation: $v=\boxed{343\,\text{m/s}}$

48 • (a) Middle C on the musical scale has a frequency of 262 Hz. What is the wavelength of this note in air? (b) The frequency of the C an octave above middle C is twice that of middle C. What is the wavelength of this note in air?

Picture the Problem The frequency, wavelength, and speed of the sound waves are related by $v=f\lambda$.

(a) The wavelength of middle C is given by:

$$\lambda=\frac{v}{f}=\frac{340\,\text{m/s}}{262\,\text{s}^{-1}}=\boxed{1.30\,\text{m}}$$

(b) Evaluate λ for a frequency twice that of middle C:

$$\lambda=\frac{v}{f}=\frac{340\,\text{m/s}}{2(262\,\text{s}^{-1})}=\boxed{0.649\,\text{m}}$$

49 • **[SSM]** The density of air is 1.29 kg/m^3. (a) What is the displacement amplitude for a sound wave with a frequency of 100 Hz and a pressure amplitude of 1.00×10^{-4} atm? (b) The displacement amplitude of a sound wave of frequency 300 Hz is 1.00×10^{-7} m. What is the pressure amplitude of this wave?

Picture the Problem The pressure amplitude depends on the density of the medium ρ, the angular frequency of the sound wave μ, the speed of the wave v, and the displacement amplitude s_0 according to $p_0=\rho\omega v s_0$.

(a) Solve $p_0=\rho\omega v s_0$ for s_0:

$$s_0=\frac{p_0}{\rho\omega v}$$

Substitute numerical values and evaluate s_0:

$$s_0 = \frac{(1.00\times10^{-4}\text{ atm})(1.01325\times10^{5}\text{ Pa/atm})}{2\pi(1.29\text{ kg/m}^3)(100\text{ s}^{-1})(343\text{ m/s})} = 3.64\times10^{-5}\text{ m} = \boxed{36.4\ \mu\text{m}}$$

(*b*) Use $p_0 = \rho\omega v s_0$ to find p_0:

$$p_0 = 2\pi(1.29\text{ kg/m}^3)(300\text{ s}^{-1})(343\text{ m/s})(1.00\times10^{-7}\text{ m}) = \boxed{83.4\text{ mPa}}$$

50 • The density of air is 1.29 kg/m^3. (*a*) What is the displacement amplitude of a sound wave that has a frequency of 500 Hz at the pain-threshold pressure amplitude of 29.0 Pa? (*b*) What is the displacement amplitude of a sound wave that has the same pressure amplitude as the wave in Part (*a*), but has a frequency of 1.00 kHz?

Picture the Problem The pressure amplitude depends on the density of the medium ρ, the angular frequency of the sound wave μ, the wave speed v, and the displacement amplitude s_0 according to $p_0 = \rho\omega v s_0$.

(*a*) Solve $p_0 = \rho\omega v s_0$ for s_0:

$$s_0 = \frac{p_0}{\rho\omega v}$$

Substitute numerical values and evaluate s_0:

$$s_0 = \frac{29.0\text{ Pa}}{2\pi(1.29\text{ kg/m}^3)(500\text{ Hz})(343\text{ m/s})} = \boxed{20.9\ \mu\text{m}}$$

(*b*) Proceed as in (*a*) with $f = 1.00$ kHz:

$$s_0 = \frac{29.0\text{ Pa}}{2\pi(1.29\text{ kg/m}^3)(1.00\text{ kHz})(343\text{ m/s})} = \boxed{10.4\ \mu\text{m}}$$

51 • A typical loud sound wave that has a frequency of 1.00 kHz has a pressure amplitude of about 1.00×10^{-4} atm. (*a*) At $t = 0$, the pressure is a maximum at some point x_1. What is the displacement at that point at $t = 0$? (*b*) Assuming the density of air is 1.29 kg/m^3, what is the maximum value of the displacement at any time and place?

Picture the Problem The pressure or density wave is 90° out of phase with the displacement wave. When the displacement is zero, the pressure and density changes are either a maximum or a minimum. When the displacement is a

maximum or minimum, the pressure and density changes are zero. We can use $p_0 = \rho\omega v s_0$ to find the maximum value of the displacement at any time and place.

(*a*) If the pressure is a maximum at x_1 when $t = 0$, the displacement s is zero.

(*b*) Solve $p_0 = \rho\omega v s_0$ for s_0:

$$s_0 = \frac{p_0}{\rho\omega v}$$

Substitute numerical values and evaluate s_0:

$$s_0 = \frac{\left(1.00\times10^{-4}\text{ atm}\right)\left(1.01325\times10^{5}\text{ Pa/atm}\right)}{2\pi\left(1.29\text{ kg/m}^3\right)\left(1.00\text{ kHz}\right)\left(343\text{ m/s}\right)} = \boxed{3.64\ \mu\text{m}}$$

52 • An octave represents a change in frequency by a factor of two. Over how many octaves can a typical person hear?

Picture the Problem A human can hear sounds between roughly 20 Hz and 20 kHz; a factor of 1000. An octave represents a change in frequency by a factor of 2. We can evaluate $2^N = 1000$ to find the number of octaves heard by a person who can hear this range of frequencies.

Relate the number of octaves to the difference between 20 kHz and 20 Hz:

$$2^N = 1000$$

Take the logarithm of both sides of the equation to obtain:

$$\log 2^N = \log 10^3 \Rightarrow N\log 2 = 3$$

Solving for N yields:

$$N = \frac{3}{\log 2} = 9.97 \approx \boxed{10}$$

53 •• In the oceans, whales communicate by sound transmission through the water. A whale emits a sound of 50.0 Hz to tell a wayward calf to catch up to the pod. The speed of sound in water is about 1500 m/s. (*a*) How long does it take the sound to reach the calf if he is 1.20 km away? (*b*) What is the wavelength of this sound in the water? (*c*) If the whales are close to the surface, some of the sound energy might refract out into the air. What would be the frequency and wavelength of the sound in the air?

Picture the Problem (*a*) We can use the definition of average speed to find the time required for the sound to travel to the calf. (*b*) We can use the relationship between wavelength, frequency, and speed to find the wavelength of the sound in water. (*c*) The frequency of the sound does not change as it travels from water to air, but its wavelength changes because of the difference in the speed of sound in water and in air.

(*a*) Relate the time it takes the sound to reach the calf to the distance from the whale to the calf and the speed of sound in water:

$$\Delta t = \frac{d}{v} = \frac{1.20\text{ km}}{1500\text{ m/s}} = \boxed{0.80\text{ s}}$$

(*b*) The wavelength of this sound in water is the ratio of its speed in water to its frequency:

$$\lambda_{\text{water}} = \frac{v_{\text{water}}}{f} = \frac{1500\text{ m/s}}{50.0\text{ Hz}} = \boxed{30\text{ m}}$$

(*c*) Because the frequency does not change as it travels from water to air:

$$f = \boxed{50.0\text{ Hz}}$$

The wavelength of this sound in air is the ratio of its speed in air to its frequency:

$$\lambda_{\text{air}} = \frac{v_{\text{air}}}{f} = \frac{343\text{ m/s}}{50.0\text{ Hz}} = \boxed{6.86\text{ m}}$$

Waves in Three Dimensions: Intensity

54 • A spherical sinusoidal source radiates sound uniformly in all directions. At a distance of 10.0 m, the sound intensity level is 1.00×10^{-4} W/m^2. (*a*) At what distance from the source is the intensity 1.00×10^{-6} W/m^2? (*b*) What power is radiated by this source?

Picture the Problem The intensity of the sound from the spherical sinusoidal source varies inversely with the square of the distance from the source. The power radiated by the source is the product of the intensity of the radiation and the surface area over which it is distributed.

(*a*) Relate the intensity I_1 at a distance R_1 from the source to the energy per unit time (power) arriving at the point of interest:

$$I_1 = \frac{P_{\text{av},1}}{4\pi R_1^2} \Rightarrow P_{\text{av},1} = 4\pi R_1^2 I_1$$

At a distance R_2 from the source:

$$I_2 = \frac{P_{\text{av},2}}{4\pi R_2^2} \Rightarrow P_{\text{av},2} = 4\pi R_2^2 I_2$$

Because $P_{\text{av},1} = P_{\text{av},2}$:

$$4\pi R_1^2 I_1 = 4\pi R_2^2 I_2 \Rightarrow R_2 = R_1\sqrt{\frac{I_1}{I_2}}$$

Substituting numerical values and evaluating R_2 gives:

$$R_2 = (10.0\text{ m})\sqrt{\frac{1.00\times10^{-4}\text{ W/m}^2}{1.00\times10^{-6}\text{ W/m}^2}} = \boxed{100\text{ m}}$$

(*b*) Solve $I = \dfrac{P_{\text{av}}}{4\pi r^2}$ for P_{av}:

$$P_{\text{av}} = 4\pi r^2 I$$

Substitute numerical values and evaluate P_{av}:

$$P_{\text{av}} = 4\pi(10.0\text{ m})^2\left(1.00\times10^{-4}\text{ W/m}^2\right) = \boxed{126\text{ mW}}$$

55 • [SSM] A loudspeaker at a rock concert generates a sound that has an intensity level equal to 1.00×10^{-2} W/m^2 at 20.0 m and has a frequency of 1.00 kHz. Assume that the speaker spreads its energy uniformly in three dimensions. (*a*) What is the total acoustic power output of the speaker? (*b*) At what distance will the sound intensity be at the pain threshold of 1.00 W/m^2? (*c*) What is the sound intensity at 30.0 m?

Picture the Problem Because the power radiated by the loudspeaker is the product of the intensity of the sound and the area over which it is distributed, we can use this relationship to find the average power, the intensity of the radiation, or the distance to the speaker for a given intensity or average power.

(*a*) Use $P_{\text{av}} = 4\pi r^2 I$ to find the total acoustic power output of the speaker:

$$P_{\text{av}} = 4\pi(20.0\text{ m})^2\left(1.00\times10^{-2}\text{ W/m}^2\right) = 50.27\text{ W} = \boxed{50.3\text{ W}}$$

(*b*) Relate the intensity of the sound at 20 m to the distance from the speaker:

$$1.00\times10^{-2}\text{ W/m}^2 = \frac{P_{\text{av}}}{4\pi(20.0\text{ m})^2}$$

Relate the threshold-of-pain intensity to the distance from the speaker:

$$1.00\ \text{W/m}^2 = \frac{P_{\text{av}}}{4\pi r^2}$$

Divide the first of these equations by the second and solve for r:

$$r = \sqrt{\left(1.00\times10^{-2}\right)\left(20.0\ \text{m}\right)^2} = \boxed{2.00\ \text{m}}$$

(c) Use $I = \dfrac{P_{\text{av}}}{4\pi r^2}$ to find the intensity at 30.0 m:

$$I\left(30.0\ \text{m}\right) = \frac{50.3\ \text{W}}{4\pi\left(30.0\ \text{m}\right)^2} = \boxed{4.45\times10^{-3}\ \text{W/m}^2}$$

56 •• When a pin of mass 0.100 g is dropped from a height of 1.00 m, 0.050 percent of its energy is converted into a sound pulse that has a duration of 0.100 s. (a) Estimate how far away the dropped pin can be heard if the minimum audible intensity is 1.00×10^{-11} W/m^2. (b) Your result in Part (a) is much too large in practice because of background noise. If you assume that the intensity must be at least 1.00×10^{-8} W/m^2 for the sound to be heard, estimate how far away the dropped pin can be heard. (In both parts, assume that the intensity is $P/4\pi r^2$.)

Picture the Problem We can use conservation of energy to find the acoustical energy resulting from the dropping of the pin. The power developed can then be found from the given time during which the energy was transformed from mechanical to acoustical form. We can find the range at which the dropped pin can be heard from $I = P/4\pi r^2$.

(a) Assuming that $I = P/4\pi r^2$, express the distance at which one can hear the dropped pin:

$$r = \sqrt{\frac{P}{4\pi I}}$$

Use conservation of energy to determine the sound energy generated when the pin falls:

$$\begin{aligned} E &= \varepsilon mgh \\ &= \left(0.00050\right)\left(0.100\times10^{-3}\ \text{kg}\right) \\ &\qquad \times\left(9.81\ \text{m/s}^2\right)\left(1.00\ \text{m}\right) \\ &= 4.905\times10^{-7}\ \text{J} \end{aligned}$$

The power of the sound pulse is given by:

$$P = \frac{E}{\Delta t} = \frac{4.905\times10^{-7}\ \text{J}}{0.100\ \text{s}} = 4.905\times10^{-6}\ \text{W}$$

Substitute numerical values and evaluate r:

$$r=\sqrt{\frac{4.905\times10^{-6}\text{ W}}{4\pi\left(1.00\times10^{-11}\text{ W/m}^2\right)}}=\boxed{0.20\text{ km}}$$

(b) Repeat the last step in (a) with $I = 1.00\times10^{-8}$ W/m^2:

$$r=\sqrt{\frac{4.905\times10^{-6}\text{ W}}{4\pi\left(1.00\times10^{-8}\text{ W/m}^2\right)}}=\boxed{6.2\text{ m}}$$

*Intensity Level

57 • **[SSM]** What is the intensity level in decibels of a sound wave that has an intensity of (a) 1.00×10^{-10} W/m^2 and (b) 1.00×10^{-2} W/m^2?

Picture the Problem The intensity level β of a sound wave, measured in decibels, is given by $\beta=(10\text{ dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing.

(a) Using its definition, calculate the intensity level of a sound wave whose intensity is 1.00×10^{-10} W/m^2:

$$\beta=(10\text{ dB})\log\left(\frac{1.00\times10^{-10}\text{ W/m}^2}{10^{-12}\text{ W/m}^2}\right)$$
$$=10\log10^2=\boxed{20.0\text{ dB}}$$

(b) Proceed as in (a) with $I = 1.00\times10^{-2}$ W/m^2:

$$\beta=(10\text{ dB})\log\left(\frac{1.00\times10^{-2}\text{ W/m}^2}{10^{-12}\text{ W/m}^2}\right)$$
$$=10\log10^{10}=\boxed{100\text{ dB}}$$

58 • What is the intensity of a sound wave if, at a particular location, the intensity level is (a) β = 10 dB and (b) β = 3 dB?

Picture the Problem (a) and (b) The intensity level β of a sound wave, measured in decibels, is given by $\beta=(10\text{ dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing.

(a) Solve $\beta=(10\text{ dB})\log(I/I_0)$ for I to obtain:

$$I=10^{\beta/(10\text{ dB})}I_0$$

Evaluate I for β = 10 dB:

$$I=10^{(10\text{ dB})/(10\text{ dB})}I_0=10I_0$$
$$=10\left(10^{-12}\text{ W/m}^2\right)=\boxed{10^{-11}\text{ W/m}^2}$$

(*b*) Proceed as in (*a*) with $\beta = 3$ dB:

$$I = 10^{(3\,\text{dB})/(10\,\text{dB})} I_0 = 2I_0$$
$$= 2\left(10^{-12}\ \text{W/m}^2\right) = \boxed{2\times 10^{-12}\ \text{W/m}^2}$$

59 • At a certain distance, the sound intensity level of a dog's bark is 50 dB. At that same distance, the sound intensity of a rock concert is 10,000 times that of the dog's bark. What is the sound intensity level of the rock concert?

Picture the Problem The intensity level β of a sound wave, measured in decibels, is given by $\beta = (10\,\text{dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing.

Express the sound intensity level of the rock concert:

$$\beta_{\text{concert}} = (10\,\text{dB})\log\left(\frac{I_{\text{concert}}}{I_0}\right) \quad (1)$$

Express the sound intensity level of the dog's bark:

$$50\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{\text{dog}}}{I_0}\right)$$

Solve for the intensity of the dog's bark:

$$I_{\text{dog}} = 10^5 I_0 = 10^5\left(10^{-12}\ \text{W/m}^2\right)$$
$$= 10^{-7}\ \text{W/m}^2$$

Express the intensity of the rock concert in terms of the intensity of the dog's bark:

$$I_{\text{concert}} = 10^4 I_{\text{dog}} = 10^4\left(10^{-7}\ \text{W/m}^2\right)$$
$$= 10^{-3}\ \text{W/m}^2$$

Substitute in equation (1) and evaluate β_{concert}:

$$\beta_{\text{concert}} = (10\,\text{dB})\log\left(\frac{10^{-3}\ \text{W/m}^2}{10^{-12}\ \text{W/m}^2}\right)$$
$$= (10\,\text{dB})\log 10^9 = \boxed{90\,\text{dB}}$$

60 • What fraction of the acoustic power of a noise would have to be eliminated to lower its sound intensity level from 90 to 70 dB?

Picture the Problem We can express the intensity levels at both 90 dB and 70 dB in terms of the intensities of the sound at those levels. By subtracting the two expressions, we can solve for the ratio of the intensities at the two levels and then find the fractional change in the intensity that corresponds to a decrease in intensity level from 90 dB to 70 dB.

Express the intensity level at 90 dB:

$$90\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{90}}{I_0}\right)$$

Express the intensity level at 70 dB:

$$70\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{70}}{I_0}\right)$$

Express $\Delta\beta = \beta_{90} - \beta_{70}$:

$$\Delta\beta = 20\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{90}}{I_0}\right) - (10\,\text{dB})\log\left(\frac{I_{70}}{I_0}\right) = (10\,\text{dB})\log\left(\frac{I_{90}}{I_{70}}\right)$$

Solving for I_{90} yields:

$$I_{90} = 100I_{70}$$

Express the fractional change in the intensity from 90 dB to 70 dB:

$$\frac{I_{90} - I_{70}}{I_{90}} = \frac{100I_{70} - I_{70}}{100I_{70}} = 99\%$$

Because $P \propto I$, the fractional change in power is $\boxed{99\%}$.

61 •• A spherical source radiates sound uniformly in all directions. At a distance of 10 m, the sound intensity level is 80 dB. (*a*) At what distance from the source is the intensity level 60 dB? (*b*) What power is radiated by this source?

Picture the Problem The intensity at a distance r from a spherical source varies with distance from the source according to $I = P_{\text{av}}/4\pi r^2$. We can use this relationship to relate the intensities corresponding to an 80-dB intensity level (I_{80}) and the intensity corresponding to a 60-dB intensity level (I_{60}) to their distances from the source. We can relate the intensities to the intensity levels through $\beta = (10\,\text{dB})\log(I/I_0)$.

(*a*) Express the intensity of the sound where the intensity level is 80 dB:

$$I_{80} = \frac{P_{\text{av}}}{4\pi r_{80}^2}$$

Express the intensity of the sound where the intensity level is 60 dB:

$$I_{60} = \frac{P_{\text{av}}}{4\pi r_{60}^2}$$

Divide the first of these equations by the second to obtain:

$$\frac{I_{80}}{I_{60}}=\frac{\dfrac{P_{\text{av}}}{4\pi(10\,\text{m})^2}}{\dfrac{P_{\text{av}}}{4\pi r_{60}^2}}=\frac{r_{60}^2}{100\,\text{m}^2}$$

Solving for r_{60} yields:

$$r_{60}=(10\,\text{m})\sqrt{\frac{I_{80}}{I_{60}}}$$

Find the intensity of the 80-dB sound level radiation:

$$80\,\text{dB}=(10\,\text{dB})\log\left(\frac{I_{80}}{I_0}\right)$$

and

$$I_{80}=10^8 I_0=10^{-4}\ \text{W/m}^2$$

Find the intensity of the 60-dB sound level radiation:

$$60\,\text{dB}=(10\,\text{dB})\log\left(\frac{I_{60}}{I_0}\right)$$

and

$$I_{60}=10^6 I_0=10^{-6}\ \text{W/m}^2$$

Substitute numerical values for I_{80} and I_{60} and evaluate r_{60}:

$$r_{60}=(10\,\text{m})\sqrt{\frac{10^{-4}\ \text{W/m}^2}{10^{-6}\ \text{W/m}^2}}=\boxed{0.10\,\text{km}}$$

(*b*) Using the intensity corresponding to an intensity level of 80 dB, express and evaluate the power radiated by this source:

$$P=I_{80}A=\left(10^{-4}\ \text{W/m}^2\right)\left[4\pi(10\,\text{m})^2\right]$$
$$=\boxed{0.13\,\text{W}}$$

62 •• Harry and Sally are sitting on opposite sides of a circus tent when an elephant trumpets a loud blast. If Harry experiences a sound intensity level of 65 dB and Sally experiences only 55 dB, what is the ratio of the distance between Sally and the elephant to the distance between Harry and the elephant?

Picture the Problem The intensity of the sound heard by Harry and Sally depends inversely on the square of the distance between the elephant and each of them. We can use the definition of sound intensity (decibel) level ($\beta=(10\text{ dB})\log(I/I_0)$) and the definition of intensity ($I=P_{\text{av}}/A$) to find the ratio of these distances.

Express the sound intensity level at Harry's location:

$$\beta_H = (10\text{ dB})\log\left(\frac{I_H}{I_0}\right) = (10\text{ dB})\log\left(\frac{P_{av}}{4\pi r_H^2 I_0}\right)$$

Similarly, the sound intensity level at Sally's location is:

$$\beta_S = (10\text{ dB})\log\left(\frac{P_{av}}{4\pi r_S^2 I_0}\right)$$

The difference in decibel level's at the two locations is given by:

$$\Delta\beta = \beta_H - \beta_S$$

Substituting for β_H, β_S, and $\Delta\beta$ yields:

$$\Delta\beta = (10\text{ dB})\log\left(\frac{P_{av}}{4\pi r_H^2 I_0}\right) - (10\text{ dB})\log\left(\frac{P_{av}}{4\pi r_S^2 I_0}\right) = 65\text{ dB} - 55\text{ dB} = 10\text{ dB}$$

Simplifying this expression yields:

$$\log\left(\frac{r_S^2}{r_H^2}\right) = 1 \Rightarrow \frac{r_S^2}{r_H^2} = 10^1$$

Solving for the ratio r_S/r_H yields:

$$\frac{r_S}{r_H} = \sqrt{10} = \boxed{3.2}$$

63 •• Three noise sources produce intensity levels of 70, 73, and 80 dB when acting separately. When the sources act together, the resultant intensity is the sum of the individual intensities. (*a*) Find the sound intensity level in decibels when the three sources act at the same time. (*b*) Discuss the effectiveness of eliminating the two least intense sources in reducing the intensity level of the noise.

Picture the Problem We can find the intensities of the three sources from their intensity levels and, because their intensities are additive, find the intensity level when all three sources are acting.

(*a*) Express the sound intensity level when the three sources act at the same time:

$$\beta_{3\,\text{sources}} = (10\,\text{dB})\log\left(\frac{I_{3\,\text{sources}}}{I_0}\right) = (10\,\text{dB})\log\left(\frac{I_{70} + I_{73} + I_{80}}{I_0}\right)$$

Find the intensities of each of the three sources:

$$70\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{70}}{I_0}\right) \Rightarrow I_{70} = 10^7 I_0$$

$$73\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{73}}{I_0}\right) \Rightarrow I_{73} = 10^{7.3} I_0$$

and

$$80\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{80}}{I_0}\right) \Rightarrow I_{80} = 10^8 I_0$$

Substituting in the expression for $\beta_{3\text{ sources}}$ yields:

$$\beta_{3\text{sources}} = (10\,\text{dB})\log\left(\frac{10^7 I_0 + 10^{7.3} I_0 + 10^8 I_0}{I_0}\right) = (10\,\text{dB})\log\left(10^7 + 10^{7.3} + 10^8\right)$$
$$= \boxed{81\,\text{dB}}$$

(*b*) Find the intensity level with the two least intense sources eliminated:

$$\beta_{80} = (10\,\text{dB})\log\left(\frac{10^8 I_0}{I_0}\right) = \boxed{80\,\text{dB}}$$

Eliminating the 70-dB and 73-dB sources does not reduce the intensity level significantly.

64 •• Show that if two people are different distances away from a sound source, the difference $\Delta\beta$ between the intensity levels reaching the people, in decibels, will always be the same, no matter the power radiated by the source.

Picture the Problem Let the two people be identified by the numerals 1 and 2 and use the definition of the intensity level, in decibels, to express $\Delta\beta$ as a function of the distances r_1 and r_2 of the two people from the source.

Express the difference in the sound intensity level heard by the two people:

$$\Delta\beta = \beta_2 - \beta_1$$

The sound level intensity (decibel level) heard by the second person is given by:

$$\beta_2 = (10\text{ dB})\log\left(\frac{I_2}{I_0}\right)$$
$$= (10\text{ dB})\log\left(\frac{P_{\text{av}}}{A_2 I_0}\right)$$
$$= (10\text{ dB})\log\left(\frac{P_{\text{av}}}{4\pi r_2^2 I_0}\right)$$

In like manner:

$$\beta_1 = (10\text{ dB})\log\left(\frac{P_{\text{av}}}{4\pi r_1^2 I_0}\right)$$

Substitute in the expression for $\Delta\beta$ to obtain:

$$\Delta\beta = (10\text{ dB})\log\left(\frac{P_{\text{av}}}{4\pi r_2^2 I_0}\right) - (10\text{ dB})\log\left(\frac{P_{\text{av}}}{4\pi r_1^2 I_0}\right)$$

Simplifying yields:

$$\Delta\beta = (10\text{ dB})\log\left(\frac{\dfrac{P_{\text{av}}}{4\pi r_2^2 I_0}}{\dfrac{P_{\text{av}}}{4\pi r_1^2 I_0}}\right)$$

$$= (10\text{ dB})\log\left(\frac{r_1^2}{r_2^2}\right)$$

This result shows that the difference in sound level ***intensities*** depends only on the distances to the source and not on the source's power output.

65 **•••** Everyone at a party is talking equally loudly. One person is talking to you and the sound intensity level at your location is 72 dB. Assuming that all 38 people at the party are at the same distance from you as the person who you are talking to, find the sound intensity level at your location.

Picture the Problem The sound intensity level can be found from the intensity of the sound due to the 38 people. When 38 people are talking, the intensities add.

Express the sound level when all 38 people are talking:

$$\beta_{38} = (10\,\text{dB})\log\left(\frac{38 I_1}{I_0}\right)$$

$$= (10\,\text{dB})\log 38 + (10\,\text{dB})\log\left(\frac{I_1}{I_0}\right)$$

$$= (10\,\text{dB})\log 38 + 72\,\text{dB}$$

$$= \boxed{88\,\text{dB}}$$

An equivalent but longer solution:

Express the sound intensity level when all 38 people are talking:

$$\beta_{38} = (10\,\text{dB})\log\left(\frac{38 I_1}{I_0}\right)$$

Express the sound intensity level when only one person is talking:

$$\beta_1 = 72\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_1}{I_0}\right)$$

Solving for I_1 yields:

$$I_1 = 10^{7.2} I_0 = 10^{7.2}\left(10^{-12}\ \text{W/m}^2\right)$$
$$= 1.58\times 10^{-5}\ \text{W/m}^2$$

Express the sound intensity when all 38 people are talking:

$$I_{38} = 38 I_1$$

The sound intensity level is:

$$\beta_{38} = (10\,\text{dB})\log\left[\frac{38\left(1.58\times 10^{-5}\ \text{W/m}^2\right)}{10^{-12}\ \text{W/m}^2}\right]$$
$$= \boxed{88\,\text{dB}}$$

66 ••• When a violinist pulls the bow across a string, the force with which the bow is pulled is fairly small, about 0.60 N. Suppose the bow travels across the A string, which vibrates at 440 Hz, at 0.50 m/s. A listener 35 m from the performer hears a sound of 60-dB intensity. Assuming that the sound radiates uniformly in all directions, with what efficiency is the mechanical energy of bowing converted to sound energy?

Picture the Problem Let η represent the efficiency with which mechanical energy is converted to sound energy. Because we're given information regarding the rate at which mechanical energy is delivered to the string and the rate at which sound energy arrives at the location of the listener, we'll take the efficiency to be the ratio of the sound power delivered to the listener divided by the power delivered to the string. We can calculate the power input directly from the given data. We'll calculate the intensity of the sound at 35 m from its intensity level at that distance and use this result to find the power output.

Express the efficiency of the conversion of mechanical energy to sound energy:

$$\eta = \frac{P_{\text{out}}}{P_{\text{in}}}$$

Find the power delivered by the bow to the string:

$$P_{\text{in}} = Fv = (0.60\,\text{N})(0.50\,\text{m/s}) = 0.30\,\text{W}$$

Using $\beta = (10\,\text{dB})\log(I/I_0)$, find the intensity of the sound at 35 m:

$$60\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{35\,\text{m}}}{I_0}\right)$$

and

$$I_{35\,\text{m}} = 10^6 I_0 = 1.00\times 10^{-6}\ \text{W/m}^2$$

The rate at which sound energy is emitted is given by:

$$P_{\text{out}} = IA = 4\pi\left(1.00\times10^{-6}\ \text{W/m}^2\right)\left(35\,\text{m}\right)^2 = 0.0154\,\text{W}$$

Substitute numerical values and evaluate η:

$$\eta = \frac{0.0154\,\text{W}}{0.30\,\text{W}} = \boxed{5.1\%}$$

67 ••• [SSM] The noise intensity level at some location in an empty examination hall is 40 dB. When 100 students are writing an exam, the noise level at that location increases to 60 dB. Assuming that the noise produced by each student contributes an equal amount of acoustic power, find the noise intensity level at that location when 50 students have left.

Picture the Problem Because the sound intensities are additive, we'll find the noise intensity level due to one student by subtracting the background noise intensity from the intensity due to the students and dividing by 100. Then, we'll use this result to calculate the intensity level due to 50 students.

Express the intensity level due to 50 students:

$$\beta_{50} = \left(10\,\text{dB}\right)\log\left(\frac{50I_1}{I_0}\right)$$

Find the sound intensity when 100 students are writing the exam:

$$60\,\text{dB} = \left(10\,\text{dB}\right)\log\left(\frac{I_{100}}{I_0}\right)$$

and

$$I_{100} = 10^6 I_0 = 10^{-6}\ \text{W/m}^2$$

Find the sound intensity due to the background noise:

$$40\,\text{dB} = \left(10\,\text{dB}\right)\log\left(\frac{I_{\text{background}}}{I_0}\right)$$

and

$$I_{\text{background}} = 10^4 I_0 = 10^{-8}\ \text{W/m}^2$$

Express the sound intensity due to the 100 students:

$$I_{100} - I_{\text{background}} = 10^{-6}\ \text{W/m}^2 - 10^{-8}\ \text{W/m}^2 \approx 10^{-6}\ \text{W/m}^2$$

Find the sound intensity due to 1 student:

$$\frac{I_{100} - I_{\text{background}}}{100} = 10^{-8}\ \text{W/m}^2$$

Substitute numerical values and evaluate the noise intensity level due to 50 students:

$$\beta_{50} = \left(10\,\text{dB}\right)\log\frac{50\left(1.00\times10^{-8}\ \text{W/m}^2\right)}{10^{-12}\ \text{W/m}^2} = \boxed{57\,\text{dB}}$$

String Waves Experiencing Speed Changes

68 • A 3.00-m-long piece of string with a mass of 25.0 g is tied to 4.00 m of heavy twine with a mass of 75.0 g and the combination is put under a tension of 100 N. If a transverse pulse is sent down the less dense string, determine the reflection and transmission coefficients at the junction point.

Picture the Problem Let the subscript ″s″ refer to the string and the subscript ″t″ to the heavy twine. We can use the definitions of the reflection and transmission coefficients and the expression for the speed of waves on a string (Equation 15-3) to find the speeds of the pulse on the string and the heavy twine.

Use their definitions to express the reflection and transmission coefficients:

$$r = \frac{v_t - v_s}{v_t + v_s} = \frac{1 - \frac{v_s}{v_t}}{1 + \frac{v_s}{v_t}} \qquad (1)$$

and

$$\tau = \frac{2v_t}{v_t + v_s} = \frac{2}{1 + \frac{v_s}{v_t}} \qquad (2)$$

Use Equation 15-3 to express v_t and v_s:

$$v_t = \sqrt{\frac{F_T}{\mu_t}} \text{ and } v_s = \sqrt{\frac{F_T}{\mu_s}}$$

Dividing the expression for v_s by the expression for v_t and simplifying yields:

$$\frac{v_s}{v_t} = \frac{\sqrt{\frac{F_T}{\mu_s}}}{\sqrt{\frac{F_T}{\mu_t}}} = \sqrt{\frac{\mu_t}{\mu_s}}$$

Substitute for v_s/v_t in equation (1) to obtain:

$$r = \frac{1 - \sqrt{\frac{\mu_t}{\mu_s}}}{1 + \sqrt{\frac{\mu_t}{\mu_s}}} \qquad (3)$$

Express the ratio of μ_t to μ_s:

$$\frac{\mu_t}{\mu_s} = \frac{\frac{m_t}{\ell_t}}{\frac{m_s}{\ell_s}} = \frac{m_t \ell_s}{m_s \ell_t}$$

Substituting in equation (3) yields:

$$r = \frac{1-\sqrt{\dfrac{m_t \ell_s}{m_s \ell_t}}}{1+\sqrt{\dfrac{m_t \ell_s}{m_s \ell_t}}}$$

Substitute numerical values and evaluate r:

$$r = \frac{1-\sqrt{\dfrac{(75.0\times10^{-3}\text{ kg})(3.00\text{ m})}{(25.0\times10^{-3}\text{ kg})(4.00\text{ m})}}}{1+\sqrt{\dfrac{(75.0\times10^{-3}\text{ kg})(3.00\text{ m})}{(25.0\times10^{-3}\text{ kg})(4.00\text{ m})}}} = \boxed{-0.20}$$

Substitute for v_s/v_t in equation (2) to obtain:

$$\tau = \frac{2}{1+\sqrt{\dfrac{\mu_t}{\mu_s}}} = \frac{2}{1+\sqrt{\dfrac{m_t \ell_s}{m_s \ell_t}}}$$

Substitute numerical values and evaluate τ:

$$\tau = \frac{2}{1+\sqrt{\dfrac{(75.0\times10^{-3}\text{ kg})(3.00\text{ m})}{(25.0\times10^{-3}\text{ kg})(4.00\text{ m})}}} = \boxed{0.80}$$

Remarks: Because $r+\tau=1$, we could have used this relationship to find τ.

69 • [SSM] Consider a taut string with a mass per unit length μ_1, carrying transverse wave pulses that are incident upon a point where the string connects to a second string with a mass per unit length μ_2. (*a*) Show that if $\mu_2 = \mu_1$, then the reflection coefficient r equals zero and the transmission coefficient τ equals +1. (*b*) Show that if $\mu_2 >> \mu_1$, then $r \approx -1$ and $\tau \approx 0$; and (*c*) if $\mu_2 << \mu_1$ then $r \approx +1$ and $\tau \approx +2$.

Picture the Problem We can use the definitions of the reflection and transmission coefficients and the expression for the speed of waves on a string (Equation 15-3) to r and t in terms of the linear densities of the strings.

(*a*) Use their definitions to express the reflection and transmission coefficients:

$$r = \frac{v_2 - v_1}{v_2 + v_1} = \frac{1 - \frac{v_1}{v_2}}{1 + \frac{v_1}{v_2}} \qquad (1)$$

and

$$\tau = \frac{2v_2}{v_2 + v_1} = \frac{2}{1 + \frac{v_1}{v_2}} \qquad (2)$$

Use Equation 15-3 to express v_2 and v_1:

$$v_2 = \sqrt{\frac{F_T}{\mu_2}} \text{ and } v_1 = \sqrt{\frac{F_T}{\mu_1}}$$

Dividing the expression for v_1 by the expression for v_2 and simplifying yields:

$$\frac{v_1}{v_2} = \frac{\sqrt{\frac{F_T}{\mu_1}}}{\sqrt{\frac{F_T}{\mu_2}}} = \sqrt{\frac{\mu_2}{\mu_1}}$$

Substitute for v_1/v_2 in equation (1) to obtain:

$$r = \frac{1 - \sqrt{\frac{\mu_2}{\mu_1}}}{1 + \sqrt{\frac{\mu_2}{\mu_1}}} \qquad (3)$$

Substitute for v_1/v_2 in equation (2) to obtain:

$$\tau = \frac{2}{1 + \sqrt{\frac{\mu_2}{\mu_1}}} \qquad (4)$$

If $\mu_2 = \mu_1$:

$$r = \frac{1 - \sqrt{1}}{1 + \sqrt{1}} = \boxed{0}$$

and

$$\tau = \frac{2}{1 + \sqrt{\frac{\mu_2}{\mu_1}}} = \frac{2}{1 + \sqrt{1}} = \boxed{1}$$

(*b*) From equations (1) and (2), if $\mu_2 >> \mu_1$ then $v_1 >> v_2$:

$$r = \frac{v_2 - v_1}{v_2 + v_1} \approx \frac{-v_1}{v_1} = \boxed{-1}$$

and

$$\tau = \frac{2v_2}{v_2 + v_1} = \frac{2}{1 + \frac{v_1}{v_2}} \approx \boxed{0}$$

(*c*) If $\mu_2 << \mu_1$, then $v_2 >> v_1$:

$$r = \frac{v_2 - v_1}{v_2 + v_1} = \frac{1 - \frac{v_1}{v_2}}{1 + \frac{v_1}{v_2}} \approx \boxed{1}$$

and

$$\tau = \frac{2v_2}{v_2 + v_1} = \frac{2}{1 + \frac{v_1}{v_2}} \approx \boxed{2}$$

70 •• Verify the validity of $1 = r^2 + (v_1/v_2)\tau^2$ (Equation 15-36) by substituting the expressions for r and τ into it.

Picture the Problem Making the indicated substitutions will lead us to the identity 1 = 1.

The reflection and transmission coefficients are given by:

$$r = \frac{v_2 - v_1}{v_2 + v_1} \text{ and } \tau = \frac{2v_2}{v_2 + v_1}$$

Substituting into the equation given in the problem statement yields:

$$1 = \left(\frac{v_2 - v_1}{v_2 + v_1}\right)^2 + \frac{v_1}{v_2}\left(\frac{2v_2}{v_2 + v_1}\right)^2$$

Simplify this expression algebraically to obtain:

$$1 = \frac{(v_2 - v_1)^2 + 4v_2^2\left(\frac{v_1}{v_2}\right)}{(v_2 + v_1)^2} = \frac{v_2^2 - 2v_2v_1 + v_1^2 + 4v_2v_1}{(v_2 + v_1)^2} = \frac{v_2^2 + 2v_2v_1 + v_1^2}{(v_2 + v_1)^2} = \frac{(v_2 + v_1)^2}{(v_2 + v_1)^2}$$
$$= \boxed{1}$$

71 ••• Consider a taut string that has a mass per unit length μ_1 carrying transverse wave pulses of the form $y = f(x - v_1t)$ that are incident upon a point P where the string connects to a second string with mass per unit length μ_2. Derive $1 = r^2 + (v_1/v_2)\tau^2$ by equating the power incident on point P to the power reflected at P plus the power transmitted at P.

Picture the Problem Choose the direction of propagation of the incident pulse as the $+x$ direction and let $x = 0$ at point P. Energy is conserved as the incident pulse is partially reflected and partially transmitted at point P.

From the conservation of energy we have:

$$P_{\text{in}} + P_{\text{r}} = P_{\text{t}} \qquad (1)$$

From Equation 15-20, the power transmitted in the direction of increasing x is given by:

$$P = -F_{\text{T}}\frac{\partial y}{\partial x}\frac{\partial y}{\partial x}$$

Substituting in equation (1) yields:

$$\left(-F_{\text{T}}\frac{\partial y_{\text{in}}}{\partial x}\frac{\partial y_{\text{in}}}{\partial x}\right)+\left(-F_{\text{T}}\frac{\partial y_{\text{r}}}{\partial x}\frac{\partial y_{\text{r}}}{\partial x}\right)=\left(-F_{\text{T}}\frac{\partial y_{\text{t}}}{\partial x}\frac{\partial y_{\text{t}}}{\partial x}\right)$$

or, upon simplification,

$$\frac{\partial y_{\text{in}}}{\partial x}\frac{\partial y_{\text{in}}}{\partial x}+\frac{\partial y_{\text{r}}}{\partial x}\frac{\partial y_{\text{r}}}{\partial x}=\frac{\partial y_{\text{t}}}{\partial x}\frac{\partial y_{\text{t}}}{\partial x} \qquad (2)$$

Because the incident pulse is given by $y_{\text{in}} = f(x - v_1 t)$, the reflected and transmitted pulses are given by:

$$y_{\text{r}} = rf(-x - v_1 t)$$

and

$$y_{\text{t}} = \tau\, f\left(\frac{v_1}{v_2}[x - v_2 t]\right)$$

Evaluating $\frac{\partial y}{\partial x}$ and $\frac{\partial y}{\partial t}$ using the chain rule yields:

$$\frac{\partial y}{\partial x} = \frac{df}{d\eta}\frac{\partial \eta}{\partial x} \text{ and } \frac{\partial y}{\partial t} = \frac{df}{d\eta}\frac{\partial \eta}{\partial t}$$

where η is the argument of the wave function.

For the transmitted pulse:

$$\frac{\partial y_{\text{t}}}{\partial x} = \tau\frac{df}{d\eta}\frac{\partial}{\partial x}\left(\frac{v_1}{v_2}[x - v_2 t]\right) = \tau\frac{df}{d\eta}\frac{v_1}{v_2}$$

and

$$\frac{\partial y_{\text{t}}}{\partial t} = \tau\frac{df}{d\eta}\frac{\partial}{\partial t}\left(\frac{v_1}{v_2}[x - v_2 t]\right) = \tau\frac{df}{d\eta}(-v_1)$$

$$= -\tau v_1\frac{df}{d\eta}$$

For the reflected pulse:

$$\frac{\partial y_{\mathrm{r}}}{\partial x}=r\frac{df}{d\eta}\frac{\partial}{\partial x}(-x-v_1t)=-r\frac{df}{d\eta}$$

and

$$\frac{\partial y_{\mathrm{r}}}{\partial t}=r\frac{df}{d\eta}\frac{\partial}{\partial t}(-x-v_1t)=r\frac{df}{d\eta}(-v_1)$$

$$=-rv_1\frac{df}{d\eta}$$

For the incident pulse:

$$\frac{\partial y_{\mathrm{in}}}{\partial x}=\frac{df}{d\eta}\frac{\partial}{\partial x}(x-v_1t)=\frac{df}{d\eta}$$

and

$$\frac{\partial y_{\mathrm{in}}}{\partial t}=\frac{df}{d\eta}\frac{\partial}{\partial t}(x-v_1t)=\frac{df}{d\eta}(-v_1)$$

$$=-v_1\frac{df}{d\eta}$$

Substitute in equation (2) to obtain:

$$\frac{df}{d\eta}\left(-v_1\frac{df}{d\eta}\right)+\left(-r\frac{df}{d\eta}\right)\left(-rv_1\frac{df}{d\eta}\right)=\left(\tau\frac{df}{d\eta}\frac{v_1}{v_2}\right)\left(-\tau v_1\frac{df}{d\eta}\right)$$

Simplifying and rearranging terms yields:

$$\boxed{1=r^2+\frac{v_1}{v_2}\tau^2}$$

The Doppler Effect

72 • A sound source is moving at 80 m/s toward a stationary listener that is standing in still air. (*a*) Find the wavelength of the sound in the region between the source and the listener. (*b*) Find the frequency heard by the listener.

Picture the Problem We can use Equation 15-38 ($\lambda=\frac{v\pm u_{\mathrm{s}}}{f_{\mathrm{s}}}$) to find the wavelength of the sound between the source and the listener and Equation15-41*a* ($f_{\mathrm{r}}=\frac{v\pm u_{\mathrm{r}}}{v\pm u_{\mathrm{s}}}f_{\mathrm{s}}$) to find the frequency heard by the listener.

(*a*) Apply Equation 15-38 to find λ:

$$\lambda=\frac{v\pm u_{\mathrm{s}}}{f_{\mathrm{s}}}=\frac{v-u_{\mathrm{s}}}{f_{\mathrm{s}}}=\frac{343\,\mathrm{m/s}-80\,\mathrm{m/s}}{200\,\mathrm{s}^{-1}}$$

$$=\boxed{1.32\,\mathrm{m}}$$

(*b*) Apply Equation 15-41*a* to obtain f_r:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{v \pm 0}{v - u_s} f_s$$
$$= \frac{343\,\text{m/s}}{343\,\text{m/s} - 80\,\text{m/s}} \left(200\,\text{s}^{-1}\right)$$
$$= \boxed{261\,\text{Hz}}$$

73 • Consider the situation described in Problem 72 from the reference frame of the source. In this frame, the listener and the air are moving toward the source at 80 m/s and the source is at rest. (*a*) At what speed, relative to the source, is the sound traveling in the region between the source and the listener? (*b*) Find the wavelength of the sound in the region between the source and the listener. (*c*) Find the frequency heard by the listener.

Picture the Problem (*a*) In the reference frame of the source, the speed of sound from the source to the listener is reduced by the speed of the air. (*b*) We can find the wavelength of the sound in the region between the source and the listener from $v = f\lambda$. (*c*) Because the sound waves in the region between the source and the listener will be compressed by the motion of the listener, the frequency of the sound heard by the listener will be higher than the frequency emitted by the source and can be calculated using $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$ (Equation 15-41*a*).

(*a*) The speed of sound in the reference frame of the source is:

$$v' = v - u_{\text{wind}} = 343\,\text{m/s} - 80\,\text{m/s}$$
$$= \boxed{263\,\text{m/s}}$$

(*b*) Noting that the frequency is unchanged, express the wavelength of the sound:

$$\lambda = \frac{v'}{f} = \frac{263\,\text{m/s}}{200\,\text{s}^{-1}} = \boxed{1.32\,\text{m}}$$

(*c*) Apply Equation 15-41*a* to obtain:

$$f_r = \frac{v' \pm u_r}{v' \pm u_s} f_s = \left(\frac{v' + u_r}{v' \pm 0}\right) f_s$$
$$= \left(\frac{263\,\text{m/s} + 80\,\text{m/s}}{263\,\text{m/s}}\right)\left(200\,\text{s}^{-1}\right)$$
$$= \boxed{261\,\text{Hz}}$$

74 • A sound source is moving away from the stationary listener at 80 m/s. (*a*) Find the wavelength of the sound waves in the region between the source and the listener. (*b*) Find the frequency heard by the listener.

Picture the Problem We can use $\lambda = (v \pm u_s)/f_s$ (Equation 15-38) to find the wavelength of the sound in the region between the source and the listener and $f_r = \dfrac{v \pm u_r}{v \pm u_s} f_s$ (Equation 15-41*a*) to find the frequency heard by the listener. Because the sound waves in the region between the source and the listener will be spread out by the motion of the listener, the frequency of the sound heard by the listener will be lower than the frequency emitted by the source.

(*a*) Because the source is moving away from the listener, use the positive sign in the numerator of Equation 15-38 to find the wavelength of the sound between the source and the listener:

$$\lambda = \frac{v \pm u_s}{f_s} = \frac{v + u_s}{f_s} = \frac{343\,\text{m/s} + 80\,\text{m/s}}{200\,\text{s}^{-1}} = \boxed{2.12\,\text{m}}$$

(*b*) Because the listener is at rest and the source is receding, $u_r = 0$ and the denominator of Equation 15-41*a* is the sum of the two speeds:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{v \pm 0}{v + u_s} f_s = \frac{343\,\text{m/s}}{343\,\text{m/s} + 80\,\text{m/s}}\left(200\,\text{s}^{-1}\right) = \boxed{162\,\text{Hz}}$$

75 • The listener is moving 80 m/s from the stationary source that is in rest relative to the air. Find the frequency heard by the listener.

Picture the Problem Because the listener is moving away from the source, we know that the frequency he/she will hear will be less than the frequency emitted by the source. We can use $f_r = \dfrac{v \pm u_r}{v \pm u_s} f_s$ (Equation 15-41a), with $u_s = 0$ and the minus sign in the numerator, to determine its value.

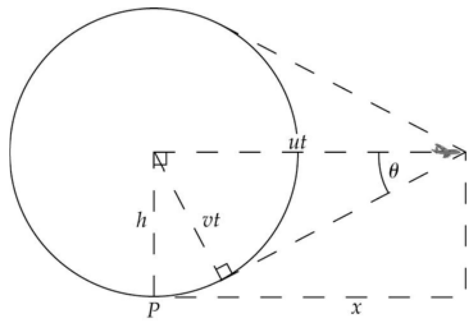
Relate the frequency heard by the listener to that of the source:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \left(\frac{v - u_r}{v \pm 0}\right) f_s = \left(\frac{343\,\text{m/s} - 80\,\text{m/s}}{343\,\text{m/s}}\right)\left(200\,\text{s}^{-1}\right) = \boxed{153\,\text{Hz}}$$

76 •• You have made the trek to observe a Space Shuttle landing. Near the end of its descent, the ship is traveling at Mach 2.50 at an altitude of 5000 m. (*a*) What is the angle that the shock wave makes with the line of flight of the shuttle? (*b*) How far are you from the shuttle by the time you hear its shock wave,

assuming the shuttle maintains both a constant heading and a constant 5000-m altitude after flying directly over your head?

Picture the Problem The diagram shows the position of the shuttle at time t after it was directly over your head (located at point P) Let u represent the speed of the shuttle and v the speed of sound. We can use trigonometry to determine the angle of the shock wave as well as the location of the shuttle x when you hear the shock wave.



(a) Referring to the diagram, express θ in terms of v, u, and t:

$$\sin\theta = \frac{vt}{ut} = \frac{1}{u/v} = \frac{1}{2.5}$$

Solving for θ yields:

$$\theta = \sin^{-1}\left(\frac{1}{2.50}\right) = 23.58° = \boxed{23.6°}$$

(b) Using the diagram, relate θ to the altitude h of the shuttle and the distance x:

$$\tan\theta = \frac{h}{x} \Rightarrow x = \frac{h}{\tan\theta}$$

Substitute numerical values and evaluate x:

$$x = \frac{5000\,\text{m}}{\tan 23.58°} = \boxed{11.5\,\text{km}}$$

77 •• The SuperKamiokande neutrino detector in Japan is a water tank the size of a 14-story building. When neutrinos collide with electrons in water, most of their energy is transferred to the electrons. As a consequence, the electrons then fly off at speeds that approach c. The neutrino is counted by detecting the shock wave, called Cerenkov radiation, that is produced when the high-speed electrons travel through the water at speeds greater than the speed of light in water. If the maximum angle of the Cerenkov shock-wave cone is 48.75°, what is the speed of light in water?

Picture the Problem The angle θ of the Cerenkov shock wave is related to the speed of light in water v and the speed of light in a vacuum c according to $\sin\theta = v/c$.

Relate the speed of light in water v to the angle of the Cerenkov cone:

$$\sin\theta = \frac{v}{c} \Rightarrow v = c\sin\theta$$

Substitute numerical values and evaluate v:

$$v = (2.998\times10^{8}\text{ m/s})\sin 48.75° = \boxed{2.254\times10^{8}\text{ m/s}}$$

78 •• You are in charge of calibrating the radar guns for a local police department. One such device emits microwaves at a frequency of 2.00 GHz. During the trials, you have it arranged so that these waves are reflected from a car moving directly away from the stationary emitter. In this situation, you detect a frequency difference (between the received microwaves and the ones sent out) of 293 Hz. Find the speed of the car.

Picture the Problem Because the car is moving away from the stationary emitter at a speed u_r, the frequency f_r it receives will be less than the frequency emitted by the emitter. The microwaves reflected from the car, moving away from a stationary detector, will be of a still lower frequency f_r'. We can use the Doppler shift equations to derive an expression for the speed of the car in terms of difference of these frequencies.

Express the frequency f_r received by the moving car in terms of f_s, u_r, and c:

$$f_r = \frac{c\pm u_r}{c\pm u_s}f_s = \left(\frac{c-u_r}{c\pm 0}\right)f_s \qquad (1)$$

The waves reflected by the car are like waves re-emitted by a source moving away from the radar gun:

$$f_r' = \frac{c\pm u_r}{c\pm u_s}f_r = \left(\frac{c}{c+u_s}\right)f_r \qquad (2)$$

Substitute equation (1) in equation (2) to eliminate f_r:

$$f_r' = \left(\frac{c}{c+u_s}\right)\left(\frac{c-u_r}{c}\right)f_s = \left(\frac{c-u_r}{c+u_s}\right)f_s$$

$$= \left(\frac{1-\frac{u_r}{c}}{1+\frac{u_r}{c}}\right)f_s = \left(1-\frac{u_r}{c}\right)\left(1+\frac{u_r}{c}\right)^{-1}f_s$$

Because $u_r << c$, $\left(1+\frac{u_r}{c}\right)^{-1} \approx 1-\frac{u_r}{c}$. Substituting for $\left(1+\frac{u_r}{c}\right)^{-1}$ and simplifying yields:

$$f_r' \approx \left(1-\frac{u_r}{c}\right)\left(1-\frac{u_r}{c}\right)f_s = \left(1-\frac{u_r}{c}\right)^{2}f_s$$

Because $u_r << c$, $\left(1-\frac{u_r}{c}\right)^2 \approx 1-\frac{2u_r}{c}$.

Substituting for $\left(1-\frac{u_r}{c}\right)^2$ gives:

$$f_r' \approx \left(1-\frac{2u_r}{c}\right)f_s$$

The frequency difference detected at the source is given by:

$$\Delta f = f_s - f_r' = f_s - \left(1-\frac{2u_r}{c}\right)f_s$$
$$= \frac{2u_r}{c}f_s$$

Solving for u_r yields:

$$u_r = \frac{c}{2f_s}\Delta f$$

Substitute numerical values and evaluate u_r:

$$u_r = \frac{2.998\times10^8\text{ m/s}}{2(2.00\,\text{GHz})}(293\,\text{Hz})$$
$$= 22.0\frac{\text{m}}{\text{s}}\times\frac{1\,\text{km}}{10^3\,\text{m}}\times\frac{3600\,\text{s}}{\text{h}}$$
$$= \boxed{79.1\,\text{km/h}}$$

79 •• [SSM] The Doppler effect is routinely used to measure the speed of winds in storm systems. As the manager of a weather monitoring station in the Midwest, you are using a Doppler radar system that has a frequency of 625 MHz to bounce a radar pulse off of the raindrops in a swirling thunderstorm system 50 km away. You measure the reflected radar pulse to be up-shifted in frequency by 325 Hz. Assuming the wind is headed directly toward you, how fast are the winds in the storm system moving? *Hint: The radar system can only measure the component of the wind velocity along its "line of sight."*

Picture the Problem Because the wind is moving toward the weather station (radar device), the frequency f_r the raindrops receive will be greater than the frequency emitted by the radar device. The radar waves reflected from the raindrops, moving toward the stationary detector at the weather station, will be of a still higher frequency f_r'. We can use the Doppler shift equations to derive an expression for the radial speed u of the wind in terms of difference of these frequencies.

Use Equation 15-41*a* to express the frequency f_r received by the raindrops in terms of f_s, u_r, and c:

$$f_r = \frac{c\pm u_r}{c\pm u_s}f_s = \left(\frac{c+u_r}{c}\right)f_s \qquad (1)$$

The waves reflected by the drops are like waves re-emitted by a source moving toward the source at the weather station:

$$f_r' = \frac{c \pm u_r}{c \pm u_s} f_r = \left(\frac{c}{c - u_s}\right) f_r \qquad (2)$$

Substitute equation (1) in equation (2) to eliminate f_r:

$$f_r' = \left(\frac{c}{c-u_s}\right)\left(\frac{c+u_r}{c}\right) f_s = \left(\frac{c+u_r}{c-u_s}\right) f_s$$

$$= \left(\frac{1+\frac{u_r}{c}}{1-\frac{u_r}{c}}\right) f_s = \left(1+\frac{u_r}{c}\right)\left(1-\frac{u_r}{c}\right)^{-1} f_s$$

Because $u_r << c$, $\left(1-\frac{u_r}{c}\right)^{-1} \approx 1+\frac{u_r}{c}$. Substituting for $\left(1-\frac{u_r}{c}\right)^{-1}$ and simplifying yields:

$$f_r' \approx \left(1+\frac{u_r}{c}\right)\left(1+\frac{u_r}{c}\right) f_s$$

$$= \left(1+\frac{u_r}{c}\right)^2 f_s$$

Because $u_r << c$, $\left(1+\frac{u_r}{c}\right)^2 \approx 1+\frac{2u_r}{c}$. Substituting for $\left(1+\frac{u_r}{c}\right)^2$ gives:

$$f_r' \approx \left(1+\frac{2u_r}{c}\right) f_s$$

The frequency difference detected at the source is:

$$\Delta f = f_r' - f_s = \left(1+\frac{2u_r}{c}\right) f_s - f_s$$

$$= \frac{2u_r}{c} f_s$$

Solving for u_r yields:

$$u_r = \frac{c}{2 f_s} \Delta f$$

Substitute numerical values and evaluate u_r:

$$u_r = \frac{2.998\times10^8 \text{ m/s}}{2(625\,\text{MHz})}(325\,\text{Hz})$$

$$= 77.95 \text{ m/s} \times \frac{1\,\text{mi/h}}{0.4470\,\text{m/s}}$$

$$= \boxed{174\,\text{mi/h}}$$

80 •• A stationary destroyer is equipped with sonar that sends out 40-MHz-pulses of sound. The destroyer receives pulses back from a submarine directly below with a time delay of 80 ms at a frequency of 39.958 MHz. If the speed of sound in seawater is 1.54 km/s, (*a*) what is the depth of the submarine? (*b*) What is its vertical speed?

Picture the Problem Let the depth of the submarine be represented by *D* and its vertical speed by *u*. The submarine acts as both a receiver and source. We can apply the definition of average speed to determine the depth of the submarine and use the Doppler shift equations to derive an expression for the vertical speed of the submarine in terms of the frequency difference. The frequency received is lower than the frequency of the source, so the sub is descending.

(*a*) Using the definition of average speed, relate the depth of the submarine to the time delay between the transmitted and reflected pulses:

$$2D = v\Delta t \Rightarrow D = \tfrac{1}{2}v\Delta t$$

Substitute numerical values and evaluate *D*:

$$D = \tfrac{1}{2}(1.54\,\text{km/s})(80\,\text{ms}) = \boxed{62\,\text{m}}$$

(*b*) Use $f_r = \left(\dfrac{v \pm u_r}{v \pm u_s}\right) f_s$ to express the frequency f_{sub} received by the submarine:

$$f_{sub} = \left(\frac{v-u}{v}\right) f_0 \qquad (1)$$

where *u* is the vertical speed of the submarine.

Use $f_r = \left(\dfrac{v \pm u_r}{v \pm u_s}\right) f_s$ to express the frequency f_r' received by the destroyer:

$$f_r' = \left(\frac{v}{v+u}\right) f_{sub} \qquad (2)$$

Substitute equation (1) in equation (2) to eliminate f_{sub}:

$$f_r' = \left(\frac{v-u}{v+u}\right) f_0 \Rightarrow u = \frac{f_0 - f_r'}{f_0 + f_r'} v$$

Substitute numerical values and evaluate *u*:

$$u = \left(\frac{40.000\,\text{MHz} - 39.958\,\text{MHz}}{40.000\,\text{MHz} + 39.958\,\text{MHz}}\right)(1.54\,\text{km/s}) = \boxed{0.81\,\text{m/s}}$$

and so, because *u* is positive, the sub is descending.

81 •• A police radar unit transmits microwaves of frequency 3.00×10^{10} Hz, and their speed in air is 3.00×10^{8} m/s. Suppose a car is receding from the stationary police car at a speed of 140 km/h. (*a*) What is the frequency difference between the transmitted signal and the signal received from the receding car? (*b*) Suppose the police car is, instead, moving at a speed of 60 km/h in the same direction as the other vehicle. What is the difference in frequency between the emitted and the reflected signals?

Picture the Problem The radar wave strikes the speeding car at frequency f_r . This frequency is less than f_s because the car is moving away from the source. The frequency shift is given by Equation 15-42 (the low-speed, relative to light, approximation). The car then acts as a moving source emitting waves of frequency f_r. The police car detects waves of frequency $f_r' < f_r$ because the source (the speeding car) is moving away from the police car. The total frequency shift is the sum of the two frequency shifts.

(*a*) Express the frequency difference Δf as the sum of the frequency difference $\Delta f_1 = f_r - f_s$ and the frequency difference $\Delta f_2 = f_r' - f_r$:

$$\Delta f = \Delta f_1 + \Delta f_2 \qquad (1)$$

Using Equation 15-42, substitute for the frequency differences in equation (1):

$$\Delta f = -\frac{u}{c} f_s - \frac{u}{c} f_r = -\frac{u}{c}\left(f_s + f_r\right) \qquad (2)$$

where $u = u_s \pm u_r$ is the speed of the source relative to the receiver.

Apply Equation 15-42 to Δf_1 to obtain:

$$\frac{\Delta f_1}{f_s} = \frac{f_r - f_s}{f_s} = -\frac{u}{c}$$

where we've used the minus sign because we know the frequency difference is a downshift.

Solving for f_r yields:

$$f_r = \left(1 - \frac{u}{c}\right) f_s$$

Substitute for f_r in equation (2) and simplify to obtain:

$$\Delta f = -\frac{u}{c}\left(f_s + \left(1 - \frac{u}{c}\right) f_s\right) = -\frac{u}{c}\left(2 - \frac{u}{c}\right) f_s$$

Because u/c is negligible compared to 2:

$$\Delta f \approx -2 f_s \frac{u}{c}$$

Substitute numerical values and evaluate Δf:

$$\Delta f \approx -2\left(3.00\times10^{10}\ \text{Hz}\right)\frac{\left(140\,\dfrac{\text{km}}{\text{h}}\times\dfrac{1\,\text{h}}{3600\,\text{s}}\right)}{3.00\times10^{8}\ \text{m/s}} = \boxed{-7.78\,\text{kHz}}$$

(b) Use the result derived in (a) with u equal to the difference in the speeds of the car and the police cruiser to obtain:

$$\Delta f \approx -2\left(3.00\times10^{10}\ \text{Hz}\right)\frac{\left(140\,\dfrac{\text{km}}{\text{h}}-60\,\dfrac{\text{km}}{\text{h}}\right)\left(\dfrac{1\,\text{h}}{3600\,\text{s}}\right)}{3.00\times10^{8}\ \text{m/s}} = \boxed{-4.4\,\text{kHz}}$$

82 •• In modern medicine, the Doppler effect is routinely used to measure the rate and direction of blood flow in arteries and veins. High frequency "ultrasound" (sound at frequencies above the human hearing range) is typically employed. Suppose you are in charge of measuring the blood flow in a vein (located in the lower leg of an older patient) that returns blood upward to the heart. Her varicose veins indicate that perhaps the one-way valves in the vein are not working properly and that the blood is "pooling" in the veins and perhaps even that the blood flow is backward toward her feet. Employing sound with a frequency of 50.0 kHz, you point the sound source from above her thigh region down towards her feet and measure the sound reflected from that vein area to be lower than 50.0 kHz. (a) Was your diagnosis of the valve condition correct? If so, explain. (b) Estimate the instrument's frequency difference capability to enable you to measure speeds down to 1.00 mm/s. Take the speed of sound in flesh to be the same as that in water, 1500 m/s.

Picture the Problem (a) Whether your diagnosis was correct depends on whether the signal reflected from the blood is upshifted or downshifted. (b) Applying the Doppler shift equations with the source stationary and the receiver moving initially and then a second time with the source moving and the receiver stationary will allow us to estimate the instrument's frequency difference capability.

(a) Because the received sound frequency is less than the frequency that was sent out, the blood it reflected from must have been moving away from the source, or toward the feet of the patient. The blood is flowing the wrong way and your diagnosis is correct.

(*b*) The blood receives a frequency that is downshifted according to:

$$f_r = \left(\frac{v \pm u_r}{v \pm u_s}\right) f_s = \left(\frac{v - u_r}{v \pm 0}\right) f_s = \left(1 - \frac{u_r}{v}\right) f_s \qquad (1)$$

The frequency given by equation (1) is the frequency emitted by the moving blood back toward the receiver. This results in a second downshift:

$$f_r' = \left(\frac{v \pm u_r}{v \pm u_s}\right) f_s' = \left(\frac{v \pm 0}{v + u_s}\right) f_s' = \left(1 + \frac{u_s}{v}\right)^{-1} f_s' \approx \left(1 - \frac{u_s}{v}\right) f_s' \qquad (2)$$

The source frequency in equation (2) is the received frequency given by equation (1). Note that the receiver and emitter speeds are the same … the speed of the blood. Let this speed be u to obtain:

$$f_r' \approx \left(1 - \frac{u}{v}\right)\left(1 - \frac{u}{v}\right) f_s \approx \left(1 - 2\frac{u}{v}\right) f_s$$

Express the magnitude of the difference in frequencies:

$$\Delta f = \left| f_s - f_r' \right| \approx \left| f_s - \left(1 - 2\frac{u}{v}\right) f_s \right| = 2\frac{u}{v} f_s$$

Substitute numerical values and evaluate Δf:

$$\Delta f \approx 2\left(\frac{1.00\text{ m/s}}{1500\text{ m/s}}\right)(50.0\text{ kHz}) = \boxed{0.033\text{ Hz}}$$

83 •• **[SSM]** A sound source of frequency f_s moves with speed u_s relative to still air toward a receiver who is moving away with speed u_r relative to still air away from the source. (*a*) Write an expression for the received frequency f'_r. (*b*) Use the result that $(1 - x)^{-1} \approx 1 + x$ to show that if both u_s and u_r are small compared to v, then the received frequency is approximately

$$f_r' = \left(1 + \frac{u_{rel}}{v}\right) f_s$$

where $u_{rel} = u_s - u_r$ is the velocity of the source relative to the receiver.

Picture the Problem The received and transmitted frequencies are related through $f_r = \dfrac{v \pm u_r}{v \pm u_s} f_s$ (Equation 15-41a), where the variables have the meanings given in the problem statement. Because the source and receiver are moving in the same direction, we use the minus signs in both the numerator and denominator.

(*a*) Relate the received frequency f_r to the frequency f_s of the source:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{1 - \dfrac{u_r}{v}}{1 - \dfrac{u_s}{v}} f_s$$

$$= \boxed{\left(1 - \frac{u_r}{v}\right)\left(1 - \frac{u_s}{v}\right)^{-1} f_s}$$

(*b*) Expand $(1 - u_s/v)^{-1}$ binomially and discard the higher-order terms:

$$\left(1 - \frac{u_s}{v}\right)^{-1} \approx 1 + \frac{u_s}{v}$$

Substitute to obtain:

$$f_r = \left(1 - \frac{u_r}{v}\right)\left(1 + \frac{u_s}{v}\right) f_s$$

$$= \left[1 + \frac{u_s}{v} - \frac{u_r}{v} - \left(\frac{u_r}{v}\right)\left(\frac{u_s}{v}\right)\right] f_s$$

$$\approx \left(1 + \frac{u_s - u_r}{v}\right) f_s$$

because both u_s and u_r are small compared to v.

Because $u_{rel} = u_s - u_r$

$$f_r' \approx \boxed{\left(1 + \frac{u_{rel}}{v}\right) f_s}$$

84 ••• To study the Doppler shift on your own, you take an electronic tone generating device that is set to a frequency of middle C (262Hz) to a campus wishing well known as ″The Abyss. ″ When you hold the device at arm's length (1.00 m), you measure its intensity level to be 80.0 dB. You then drop the tuner down the hole, listening to its sound as it falls. After the tuner has fallen for 5.50 s, what frequency do you hear?

Picture the Problem As the tuner falls, its speed increases and so the frequency you hear is Doppler shifted. Our concern, however, is with the frequency you hear 5.50 s after you've dropped the tuner. The sound that you hear at this time was emitted sometime before the tuner had fallen for 5.50 s. Hence we must answer the question ″At what time was the sound emitted that you heard 5.50 s after dropping the tuner?″

Apply Equation 15-41a to express the frequency you'll hear after 5.50 s:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{v}{v + v_{fall}} f_s \qquad (1)$$

Relate the elapsed time of 5.50 s to the time required for the tuner to fall and the time for the sound to return to you:

$$\Delta t_{tot} = \Delta t_{fall} + \Delta t_{return} \qquad (2)$$

Use a constant-acceleration equation to relate the time-of-fall to the fall distance:

$$\Delta y = \tfrac{1}{2} g (\Delta t_{fall})^2 \Rightarrow \Delta t_{fall} = \sqrt{\frac{2\Delta y}{g}}$$

The return time depends on how far the tuner has fallen and on the speed of sound in air:

$$\Delta t_{return} = \frac{\Delta y}{v} \Rightarrow \Delta y = v \Delta t_{return}$$

Substituting for Δy in the expression for Δt_{fall} yields:

$$\Delta t_{fall} = \sqrt{\frac{2v\Delta t_{return}}{g}}$$

Square both sides of the equation, use equation (2) to substitute for Δt_{return}, and write the result explicitly as a quadratic equation to obtain:

$$(\Delta t_{fall})^2 + \frac{2v}{g}(\Delta t_{fall}) - \frac{2v}{g}\Delta t_{tot} = 0$$

Substitute numerical values to obtain:

$$(\Delta t_{fall})^2 + \frac{2(343\ \text{m/s})}{9.81\ \text{m/s}^2}(\Delta t_{fall}) - \frac{2(343\ \text{m/s})(5.50\ \text{s})}{9.81\ \text{m/s}^2} = 0$$

or

$$(\Delta t_{fall})^2 + (69.93\ \text{s})(\Delta t_{fall}) - 384.6\ \text{s}^2 = 0$$

Use your graphing calculator or the quadratic formula to solve this equation for its positive root:

$$\Delta t_{\text{fall}} = 5.124\text{ s}$$

Because $v_{\text{fall}} = g\Delta t_{\text{fall}}$, equation (1) becomes:

$$f_{\text{r}} = \frac{v}{v + g\Delta t_{\text{fall}}} f_{\text{s}}$$

Substitute numerical values and evaluate f_{r}:

$$f_{\text{r}} = \frac{343\text{ m/s}}{343\text{ m/s} + (9.81\text{ m/s}^2)(5.124\text{ s})}(262\text{ Hz}) = \boxed{229\text{ Hz}}$$

85 •• You are in a hot-air balloon carried along by a 36-km/h wind and have a sound source with you that emits a sound of 800 Hz as it approaches a tall building. (*a*) What is the frequency of the sound heard by an observer at the window of this building? (*b*) What is the frequency of the reflected sound heard by you?

Picture the Problem The simplest way to approach this problem is to transform to a reference frame in which the balloon is at rest. In that reference frame, the speed of sound is v = 343 m/s, and u_{r} = 36 km/h = 10 m/s. Then, we can use the equations for a moving receiver and a moving source to find the frequencies heard at the window and on the balloon.

(*a*) Use Equation 15-41*a* to express the received frequency in terms of the frequency of the source:

$$f_{\text{r}} = \frac{v \pm u_{\text{r}}}{v \pm u_{\text{s}}} f_{\text{s}} = \frac{1 \pm \frac{u_{\text{r}}}{v}}{1 \pm \frac{u_{\text{s}}}{v}} f_{\text{s}} = \frac{1 + \frac{u_{\text{r}}}{v}}{1 \pm \frac{0}{v}} f_{\text{s}}$$

$$= \left(1 + \frac{u_{\text{r}}}{v}\right) f_{\text{s}}$$

Substitute numerical values and evaluate f_{r}:

$$f_{\text{r}} = \left(1 + \frac{10\text{ m/s}}{343\text{ m/s}}\right)(800\text{ Hz}) = 823\text{ Hz}$$

$$= \boxed{0.82\text{ kHz}}$$

(*b*) Treating the tall building as a moving source, express the frequency of the reflected sound heard by a person riding in the balloon:

$$f_r' = \frac{v \pm u_r}{v \pm u_s} f_r = \frac{1 \pm \frac{u_r}{v}}{1 \pm \frac{u_s}{v}} f_r = \frac{1 \pm \frac{0}{v}}{1 - \frac{u_s}{v}} f_r = \left(\frac{1}{1 - \frac{u_s}{v}} \right) f_r$$

Substitute numerical values and evaluate f_r':

$$f_r' = \left(\frac{1}{1 - \frac{10\,\text{m/s}}{343\,\text{m/s}}} \right) (823\,\text{Hz}) = \boxed{0.85\,\text{kHz}}$$

86 •• A car is approaching a reflecting wall. A stationary observer behind the car hears a sound of frequency 745 Hz from the car horn and a sound of frequency 863 Hz from the wall. (*a*) How fast is the car traveling? (*b*) What is the frequency of the car horn? (*c*) What frequency does the car driver hear reflected from the wall?

Picture the Problem We can relate the frequencies f_r and f_r' heard by the stationary observer behind the car to the speed of the car u_r and the frequency of the car's horn f_s. Dividing these equations will eliminate the frequency of the car's horn and allow us to solve for the speed of the car. We can then substitute to find the frequency of the car's horn. We can find the frequency heard by the driver as a moving receiver by relating this frequency to the frequency reflected from the wall.

(*a*) Use Equation 15-41*a* to relate the frequency heard by the observer directly from the car's horn to the speed of the car:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{1 \pm \frac{u_r}{v}}{1 \pm \frac{u_s}{v}} f_s = \frac{1 \pm \frac{0}{v}}{1 + \frac{u_s}{v}} f_s = \frac{1}{1 + \frac{u_s}{v}} f_s \qquad (1)$$

Relate the frequency reflected from the wall to the speed of the car:

$$f_r' = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{1 \pm \frac{0}{v}}{1 - \frac{u_s}{v}} f_s = \frac{1}{1 - \frac{u_s}{v}} f_s \qquad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{f_r'}{f_r} = \frac{1 + \frac{u_s}{v}}{1 - \frac{u_s}{v}} \Rightarrow u = \frac{f_r' - f_r}{f_r' + f_r'} v$$

Substitute numerical values and evaluate u_s:

$$u_s = \frac{863\,\text{Hz} - 745\,\text{Hz}}{863\,\text{Hz} + 745\,\text{Hz}}(343\,\text{m/s}) = 25.17\,\frac{\text{m}}{\text{s}} \times \frac{1\,\text{km}}{10^3\,\text{m}} \times \frac{3600\,\text{s}}{\text{h}} = \boxed{90.6\,\text{km/h}}$$

(*b*) Solve equation (1) for f_s to obtain:

$$f_s = \left(1 + \frac{u_r}{v}\right) f_r$$

Substitute numerical values and evaluate f_s:

$$f_s = \left(1 + \frac{25.17\,\text{m/s}}{343\,\text{m/s}}\right)(745\,\text{Hz}) = \boxed{800\,\text{Hz}}$$

(*c*) The driver is a moving receiver and so we can relate the frequency heard by the driver to the frequency reflected by the wall (the frequency heard by the stationary observer):

$$f_{\text{driver}} = \left(1 + \frac{u_r}{v}\right) f_r'$$

Substitute numerical values and evaluate f_{driver}:

$$f_{\text{driver}} = \left(1 + \frac{25.17\,\text{m/s}}{343\,\text{m/s}}\right)(863\,\text{H}z) = \boxed{926\,\text{Hz}}$$

87 •• The driver of a car traveling at 100 km/h toward a vertical wall briefly sounds the horn. Exactly 1.00 s later she hears the echo and notes that its frequency is 840 Hz. How far from the wall was the car when the driver sounded the horn and what is the frequency of the horn?

Picture the Problem Let $t = 0$ when the driver sounds her horn and let the distance to the wall at that instant be d. The received and transmitted frequencies are related through $f_{\text{r}} = \dfrac{v \pm u_{\text{r}}}{v \pm u_{\text{s}}} f_{\text{s}}$ (Equation 15-41*a*). Solving this equation for f_{s} will allow us to determine the frequency of the car horn. We can use the total distance the sound travels (car-to-wall plus wall-back to-car … now closer to the wall) to determine the distance to the wall when the horn was briefly sounded.

Use Equation 15-41*a* to relate the frequency heard by the driver to her speed and to the frequency of her horn:

$$f_{\text{r}} = \frac{v \pm u_{\text{r}}}{v \pm u_{\text{s}}} f_{\text{s}} = \frac{1 \pm \dfrac{u_{\text{r}}}{v}}{1 \pm \dfrac{u_{\text{s}}}{v}} f_{\text{s}} = \frac{1 + \dfrac{u_{\text{r}}}{v}}{1 - \dfrac{u_{\text{s}}}{v}} f_{\text{s}}$$

Solving for f_{s} yields:

$$f_{\text{s}} = \frac{1 - \dfrac{u_{\text{s}}}{v}}{1 + \dfrac{u_{\text{r}}}{v}} f_{\text{r}}$$

Substitute numerical values and evaluate f_{s}:

$$f_{\text{s}} = \frac{1 - \dfrac{100 \dfrac{\text{km}}{\text{h}} \times \dfrac{1\,\text{h}}{3600\,\text{s}}}{343\,\text{m/s}}}{1 + \dfrac{100 \dfrac{\text{km}}{\text{h}} \times \dfrac{1\,\text{h}}{3600\,\text{s}}}{343\,\text{m/s}}} (840\,\text{Hz}) = \frac{1 - \dfrac{27.78\,\text{m/s}}{343\,\text{m/s}}}{1 + \dfrac{27.78\,\text{m/s}}{343\,\text{m/s}}} (840\,\text{Hz}) = \boxed{714\,\text{Hz}}$$

Relate the distance d to the wall at $t = 0$ to the distance she travels in time $\Delta t = 1$ s, her speed u_{s}, and the speed of sound v:

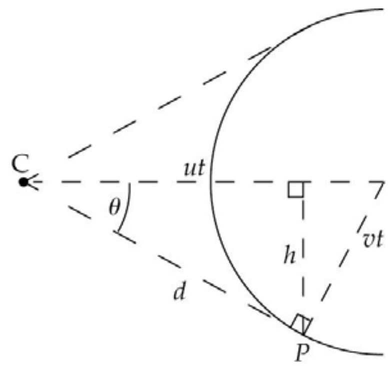
$$d + (d - u_{\text{s}}\Delta t) = v\Delta t \Rightarrow d = \tfrac{1}{2}(u_{\text{s}} + v)\Delta t$$

Substitute numerical values and evaluate d:

$$d = \tfrac{1}{2}(27.78\,\text{m/s} + 343\,\text{m/s})(1.00\,\text{s}) = \boxed{185\,\text{m}}$$

88 •• You are on a transatlantic flight traveling due west at 800 km/h. An experimental plane flying at Mach 1.6 and 3.0 km to the north of your plane is also on an east-to-west course. What is the distance between the two planes when you hear the sonic boom from the experimental plane?

Picture the Problem You'll hear the sonic boom when the surface of its cone reaches your plane. In the following diagram, the experimental plane is at C and your plane is at P. The distance h = 3.0 km. The distance between the planes when you hear the sonic boom is d. We can use trigonometry to determine the angle of the shock wave as well as the separation of the planes when you hear the sonic boom.



Using the Pythagorean theorem, relate the separation of the planes d, to the distance h and the angle θ:

$$d^2 = h^2 + d^2\cos^2\theta \Rightarrow d = h\sqrt{\frac{1}{1-\cos^2\theta}}$$

Express θ in terms of v, u, and t:

$$\sin\theta = \frac{vt}{ut} = \frac{1}{u/v} = \frac{1}{1.6}$$

so

$$\theta = \sin^{-1}\left(\frac{1}{1.6}\right) = 38.7°$$

Substitute numerical values and evaluate d:

$$d = (3.0\,\text{km})\sqrt{\frac{1}{1-\cos^2 38.7°}} = \boxed{4.8\,\text{km}}$$

89 ••• The Hubble space telescope has been used to determine the existence of planets orbiting distant stars. The planet orbiting the star will cause the star to ″wobble″ with the same period as the planet's orbit. Because of wobble, light from the star will be Doppler-shifted up and down periodically. Estimate the maximum and minimum wavelengths of light of nominal wavelength 500 nm emitted by the Sun that is Doppler-shifted by the motion of the Sun due to the planet Jupiter.

Picture the Problem The Sun and Jupiter orbit about their effective mass located at their common center of mass. We can apply Newton's second law to the Sun to obtain an expression for its orbital speed about the Sun-Jupiter center of mass and then use this speed in the Doppler shift equation to estimate the maximum and minimum wavelengths resulting from the Jupiter-induced motion of the Sun.

Letting v be the orbital speed of the sun about the center of mass of the Sun-Jupiter system, express the Doppler shift of the light due to this motion when the Sun is approaching Earth:

$$f' = \frac{c}{\lambda'} = f\sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}} = \frac{c}{\lambda}\sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}}$$

Solving for λ' and simplifying yields:

$$\lambda' = \lambda\sqrt{\frac{1-\frac{v}{c}}{1+\frac{v}{c}}} = \lambda\sqrt{\left(1-\frac{v}{c}\right)\left(1+\frac{v}{c}\right)^{-1}}$$

$$= \lambda\left(1-\frac{v}{c}\right)^{1/2}\left(1+\frac{v}{c}\right)^{-1/2}$$

Because $v << c,$ we can expand $\left(1-\frac{v}{c}\right)^{1/2}$ and $\left(1+\frac{v}{c}\right)^{-1/2}$ binomially to obtain:

$$\left(1-\frac{v}{c}\right)^{1/2} \approx 1-\frac{v}{2c}$$

and

$$\left(1+\frac{v}{c}\right)^{-1/2} \approx 1-\frac{v}{2c}$$

Substitute for $\left(1-\frac{v}{c}\right)^{1/2}$ and $\left(1+\frac{v}{c}\right)^{-1/2}$ to obtain:

$$\sqrt{\frac{1-\frac{v}{c}}{1+\frac{v}{c}}} = \left(1-\frac{v}{2c}\right)^2 \approx 1-\frac{v}{c}$$

When the Sun is receding from Earth:

$$\sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}} = \left(1+\frac{v}{2c}\right)^2 \approx 1+\frac{v}{c}$$

Hence the motion of the Sun will give an observed Doppler shift of:

$$\lambda' \approx \lambda\left(1\pm\frac{v}{c}\right) \qquad (1)$$

Apply Newton's second law to the Sun:

$$\frac{GM_S M_{eff}}{r_{cm}^2} = M_S \frac{v^2}{r_{cm}} \Rightarrow v = \sqrt{\frac{GM_{eff}}{r_{cm}}}$$

Measured from the center of the Sun, the distance to the center of mass of the Sun-Jupiter system is:

$$r_{cm} = \frac{(0)M_S + r_{s\text{-}J} M_J}{M_s + M_J} = \frac{r_{s\text{-}J} M_J}{M_s + M_J}$$

The effective mass is related to the masses of the Sun and Jupiter according to:

$$\frac{1}{M_{eff}} = \frac{1}{M_s} + \frac{1}{M_J} \Rightarrow M_{eff} = \frac{M_s M_J}{M_s + M_J}$$

Substitute for M_{eff} and r_{cm} to obtain:

$$v = \sqrt{\frac{G\dfrac{M_s M_J}{M_s + M_J}}{\dfrac{r_{s\text{-}J} M_J}{M_s + M_J}}} = \sqrt{\frac{GM_s}{r_{s\text{-}J}}}$$

Using $r_{s\text{-}J} = 7.78 \times 10^{11}$ m as the mean orbital radius of Jupiter, substitute numerical values and evaluate v:

$$v = \sqrt{\frac{(6.673 \times 10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.99 \times 10^{30}\ \text{kg})}{7.78 \times 10^{11}\ \text{m}}} = 1.306 \times 10^4\ \text{m/s}$$

Substitute numerical values in equation (1) to obtain:

$$\lambda' \approx (500\,\text{nm})\left(1 \pm \frac{1.306 \times 10^4\ \text{m/s}}{2.998 \times 10^8\ \text{m/s}}\right)$$
$$= (500\,\text{nm})(1 \pm 4.36 \times 10^{-5})$$

The maximum and minimum wavelengths are:

$$\lambda_{max} = \boxed{500.02\ \text{nm}}$$

and

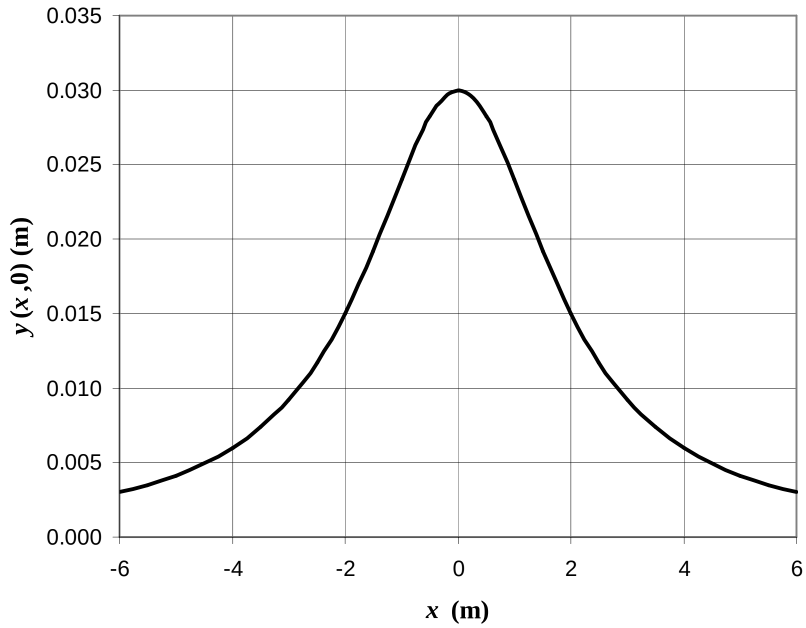
$$\lambda_{min} = \boxed{499.98\ \text{nm}}$$

General Problems

90 • At time $t = 0$, the shape of a wave pulse on a string is given by the function $y(x,0) = 0.120\ \text{m}^3/\left((2.00\ \text{m})^2 + x^2\right)$, where x is in meters. (*a*) Sketch $y(x, 0)$ versus x. (*b*) Give the wave function $y(x,t)$ at a general time t if the pulse is moving in the $+x$ direction with a speed of 10.0 m/s and if the pulse is moving in the $-x$ direction with a speed of 10.0 m/s.

Picture the Problem The equation of a wave traveling in the +x direction is of the form $y(x,t)=f(x-vt)$ and that of a wave traveling in the –x direction is $y(x,t)=f(x+vt)$.

(a) The pulse at t = 0 shown below was plotted using a spreadsheet program:



(b) If the pulse is moving in the +x direction, the wave function must be of the form:

$$y(x,t)=f(x-vt)=f[x-(10.0\,\text{m/s})t]$$

because v = 10.0 m/s

Replace x with $x-(10.0\,\text{m/s})t$ to obtain:

$$y(x,t)=\boxed{\frac{0.120\,\text{m}^3}{(2.00\,\text{m})^2+[x-(10.0\,\text{m/s})t]^2}}$$

If the pulse is moving in the –x direction, the wave function must be of the form:

$$y(x,t)=f(x+vt)=f[x+(10.0\,\text{m/s})t]$$

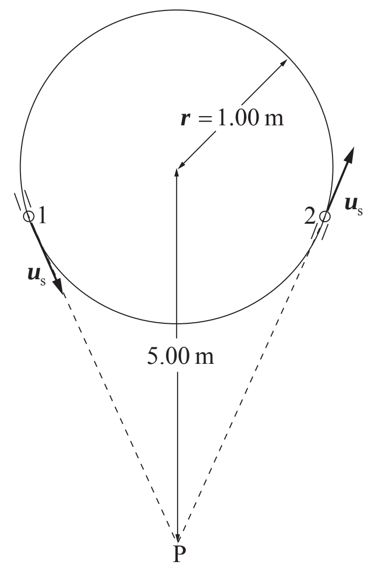
because v = 10.0 m/s

Replace x with $x+(10.0\,\text{m/s})t$ to obtain:

$$y(x,t)=\boxed{\frac{0.120\,\text{m}^3}{(2.00\,\text{m})^2+[x+(10.0\,\text{m/s})t]^2}}$$

91 • [SSM] A whistle that has a frequency of 500 Hz moves in a circle of radius 1.00 m at 3.00 rev/s. What are the maximum and minimum frequencies heard by a stationary listener in the plane of the circle and 5.00 m away from its center?

Picture the Problem The pictorial representation depicts the whistle traveling in a circular path of radius r = 1.00 m. The stationary listener will hear the maximum frequency when the whistle is at point 1 and the minimum frequency when it is at point 2. These maximum and minimum frequencies are determined by f_0 and the tangential speed $u_s = 2\pi\, r/T$. We can relate the frequencies heard at point P to the speed of the approaching whistle at point 1 and the speed of the receding whistle at point 2.



Relate the frequency heard at point P to the speed of the approaching whistle at point 1:

$$f_{max} = \frac{1}{1 - \dfrac{u_s}{v}} f_s$$

Because $u_s = r\omega$:

$$f_{max} = \frac{1}{1 - \dfrac{r\omega}{v}} f_s$$

Substitute numerical values and evaluate f_{max}:

$$f_{max} = \frac{1}{1 - \dfrac{(1.00\,\text{m})\left(3.00\,\dfrac{\text{rev}}{\text{s}} \times \dfrac{2\pi\,\text{rad}}{\text{rev}}\right)}{343\,\text{m/s}}}(500\,\text{Hz}) = \boxed{529\,\text{Hz}}$$

Relate the frequency heard at point P to the speed of the receding whistle at point 2:

$$f_{min} = \frac{1}{1 + \dfrac{u_s}{v}} f_s$$

Substitute numerical values and evaluate $f_{\min}$:

$$f_{\min}=\frac{1}{1+\dfrac{(1.00\,\text{m})\left(3.00\,\dfrac{\text{rev}}{\text{s}}\times\dfrac{2\pi\,\text{rad}}{\text{rev}}\right)}{343\,\text{m/s}}}(500\,\text{Hz})=\boxed{474\,\text{Hz}}$$

92 • Ocean waves move toward the beach with a speed of 8.90 m/s and a crest-to-crest separation of 15.0 m. You are in a small boat anchored off shore. (*a*) At what frequency do the wave crests reach you boat? (*b*) You now lift anchor and head out to sea at a speed of 15.0 m/s. At what frequency do the wave crests reach your boat now?

Picture the Problem (*a*) The crest-to-crest separation of the waves is their wavelength. We can find the frequency of the waves from $v = f\lambda$. (*b*) When you lift anchor and head out to sea you'll become a moving receiver and we can apply $f_{\text{r}}=\dfrac{v\pm u_{\text{r}}}{v\pm u_{\text{s}}}f_{\text{s}}$ to calculate the frequency you'll observe.

(*a*) The frequency of the ocean waves is the ratio of their speed to their wavelength:

$$f_0=\frac{v}{\lambda}=\frac{8.90\,\text{m/s}}{15.0\,\text{m}}=\boxed{0.593\,\text{Hz}}$$

(*b*) Express the frequency of the waves in terms of their speed and the speed of a moving receiver:

$$f_{\text{r}}=\frac{v\pm u_{\text{r}}}{v\pm u_{\text{s}}}f_{\text{s}}=\frac{v+u_{\text{r}}}{v}f_{\text{s}}=\left(1+\frac{u_{\text{r}}}{v}\right)f_{\text{s}}$$

Substitute numerical values and evaluate f_{r}:

$$f_{\text{r}}=\left(1+\frac{15.0\,\text{m/s}}{8.90\,\text{m/s}}\right)(0.593\,\text{Hz})$$

$$=\boxed{1.59\,\text{Hz}}$$

93 •• A 12.0-m-long wire that has an 85.0-g mass is stretched under a tension of 180 N. A pulse is generated at the left end of the wire, and 25.0 ms later a second pulse is generated at the right end of the wire. Where do the pulses first meet?

Picture the Problem Let t be the time of travel of the left-hand pulse and the subscripts L and R refer to the pulse coming from the left and right, respectively. Because the pulse traveling from the right starts later than the pulse from the left, its travel time is $t - \Delta t$, where Δt = 25.0 ms. Both pulses travel at the same speed and the sum of the distances they travel is 12.0 m.

Express the total distance the two pulses travel:

$$d = d_L + d_R = vt + v(t - \Delta t)$$

Solve for vt to obtain:

$$vt = \tfrac{1}{2}(d + v\Delta t)$$

The speed of the pulse is given by:

$$v = \sqrt{\frac{F_T}{\mu}} = \sqrt{\frac{F_T}{m/L}}$$

Substituting for v yields:

$$vt = \tfrac{1}{2}\left(d + \sqrt{\frac{F_T}{m/L}}\Delta t\right)$$

Substitute numerical values and evaluate vt:

$$vt = \tfrac{1}{2}\left[12.0\,\text{m} + \sqrt{\frac{(180\,\text{N})(12.0\,\text{m})}{0.085\,\text{kg}}}\left(25.0\times10^{-3}\,\text{s}\right)\right] = \boxed{7.99\,\text{m}}$$

from the left end of the wire.

94 •• You are parked on the shoulder of a highway. Find the speed of a car in which the tone of the car's horn drops by 10 percent as it passes you. (In other words, the total drop in frequency between the ″approach″ value and the ″recession″ value is 10%.)

Picture the Problem Let the frequency of the car's horn be f_s, the frequency you hear as the car approaches be f_r, and the frequency you hear as the car recedes be f_r'. We can use $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$ to express the frequencies heard as the car approaches and recedes and then use these frequencies to express the fractional change in frequency as the car passes you.

Express the fractional change in frequency as the car passes you:

$$\frac{\Delta f}{f_r} = 0.10$$

Relate the frequency heard as the car approaches to the speed of the car:

$$f_r = \frac{v \pm u_r}{v \pm u_s} f_s = \frac{v \pm 0}{v - u_s} f_s = \frac{1}{1 - \frac{u_s}{v}} f_s$$

Express the frequency heard as the car recedes in terms of the speed of the car:

$$f_r' = \frac{1}{1+\frac{u_s}{v}} f_s$$

Divide the second of these frequency equations by the first to obtain:

$$\frac{f_r'}{f_r} = \frac{1-\frac{u_s}{v}}{1+\frac{u_s}{v}}$$

and

$$\frac{f_r}{f_r} - \frac{f_r'}{f_r} = \frac{\Delta f}{f_r} = 1 - \frac{1-\frac{u_s}{v}}{1+\frac{u_s}{v}} = 0.10$$

Solving for u_s yields:

$$u_s = \frac{0.10}{1.9} v$$

Substitute numerical values and evaluate u_s:

$$u_s = \frac{0.10}{1.9}(343\,\text{m/s})$$
$$= 18.05\frac{\text{m}}{\text{s}} \times \frac{1\,\text{km}}{10^3} \times \frac{3600\,\text{s}}{\text{h}}$$
$$= \boxed{65\,\text{km/h}}$$

95 •• [SSM] A loudspeaker driver 20.0 cm in diameter is vibrating at 800 Hz with an amplitude of 0.0250 mm. Assuming that the air molecules in the vicinity have the same amplitude of vibration, find (*a*) the pressure amplitude immediately in front of the driver, (*b*) the sound intensity, and (*c*) the acoustic power being radiated by the front surface of the driver.

Picture the Problem (*a*) and (*b*) The pressure amplitude can be calculated directly from $p_0 = \rho\omega v s_0$, and the intensity from $I = \frac{1}{2}\rho\omega^2 s_0^2 v$. (*c*) The power radiated is the intensity times the area of the driver.

(*a*) Relate the pressure amplitude to the displacement amplitude, angular frequency, wave velocity, and air density:

$$p_0 = \rho\omega v s_0$$

Substitute numerical values and evaluate p_0:

$$p_0 = (1.29\,\text{kg/m}^3)\left[2\pi(800\,\text{s}^{-1})\right] \times (343\,\text{m/s})(0.0250\times10^{-3}\,\text{m})$$
$$= \boxed{55.6\,\text{N/m}^2}$$

(*b*) Relate the intensity to these same quantities:

$$I = \tfrac{1}{2}\rho\omega^2 s_0^2 v$$

Substitute numerical values and evaluate *I*:

$$I = \tfrac{1}{2}\left(1.29\,\text{kg/m}^3\right)\left[2\pi\left(800\,\text{s}^{-1}\right)\right]^2 \times\left(0.0250\times10^{-3}\,\text{m}\right)^2\left(343\,\text{m/s}\right) = 3.494\,\text{W/m}^2 = \boxed{3.49\,\text{W/m}^2}$$

(*c*) Express the power in terms of the intensity and the area of the driver:

$$P = IA = \pi r^2 I$$

Substitute numerical values and evaluate *P*:

$$P = \pi\left(0.100\,\text{m}\right)^2\left(3.494\,\text{W/m}^2\right) = \boxed{0.110\,\text{W}}$$

96 •• A plane, harmonic, sound wave in air has an amplitude of 1.00 μm and an intensity of 10.0 mW/m^2. What is the frequency of the wave?

Picture the Problem The frequency of the wave is related to the density of the air, displacement amplitude, and velocity by $I = \tfrac{1}{2}\rho\omega^2 s_0^2 v$.

Relate the intensity of the wave to the density of the air, displacement amplitude, velocity, and angular frequency:

$$I = \tfrac{1}{2}\rho\omega^2 s_0^2 v \Rightarrow \omega = \frac{1}{s_0}\sqrt{\frac{2I}{\rho v}}$$

Because $\omega = 2\pi f$:

$$f = \frac{1}{2\pi s_0}\sqrt{\frac{2I}{\rho v}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi\left(1.00\times10^{-6}\,\text{m}\right)}\sqrt{\frac{2\left(1.00\times10^{-2}\,\text{W/m}^2\right)}{\left(1.29\,\text{kg/m}^3\right)\left(343\,\text{m/s}\right)}} = \boxed{1.07\,\text{kHz}}$$

97 •• Water flows at 7.0 m/s in a pipe of radius 5.0 cm. A plate with area equal to the cross-sectional area of the pipe is suddenly inserted to stop the flow. Find the force exerted on the plate. Take the speed of sound in water to be 1.4 km/s. *Hint: When the plate is inserted, a pressure wave propagates through the water at the speed of sound v_s. The mass of water brought to a stop in time Δt is the water in a length of pipe equal to $v_s\Delta t$.*

Picture the Problem The force exerted on the plate is due to the change in momentum of the water. We can use Newton's second law in the form $F = \Delta p/\Delta t$ to relate F to the mass of water in a length of pipe equal to $v_s\Delta t$ and to the speed of the water. This mass of water, in turn, is given by the product of its density and the volume of water in a length of pipe equal to $v_s\Delta t$.

Relate the force exerted on the plate to the change in momentum of the water:

$$F = \frac{\Delta p}{\Delta t} = \frac{\Delta m v_w}{\Delta t}$$

Express Δm in terms of the mass of water in a length of pipe equal to $v_s\Delta t$:

$$\Delta m = \rho \Delta V = \rho v_s A \Delta t$$

Substitute for Δm to obtain:

$$F = \rho v_s A v_w$$

Substitute numerical values and evaluate F:

$$F = \left(1.00\times10^3\ \text{kg/m}^3\right)\left(1.4\,\text{km/s}\right)\left[\pi\left(0.050\,\text{m}\right)^2\right]\left(7.0\,\text{m/s}\right) = \boxed{77\,\text{kN}}$$

98 •• A high-speed flash photography setup to capture a picture of a bullet exploding a soap bubble is shown in Figure 15-33. The shock wave from the bullet is to be detected by a microphone that will trigger the flash. The microphone is placed on a track that is parallel to, and 0.350 m below, the path of the bullet. The track is used to adjust the position of the microphone. If the bullet is traveling at 1.25 times the speed of sound, how far back from the soap bubble must the microphone be set to trigger the flash? (Assume that the flash itself is instantaneous once the microphone is triggered.)

Picture the Problem Let d be the horizontal distance from the soap bubble to the position of the microphone. The angle θ of the shock wave is related to the speed of sound in air u and the speed of the bullet v according to $\sin\theta = u/v$. We can determine θ from the given information and then use this angle to find d.

Express d in terms of the angle of the shock wave and the distance from the soap bubble to the laboratory bench:

$$d = \frac{0.350\,\text{m}}{\tan\theta} \qquad (1)$$

Relate the speed of the bullet to the angle of the shock-wave cone:

$$\sin\theta = \frac{u}{v} \Rightarrow \theta = \sin^{-1}\left(\frac{u}{v}\right)$$

Substitute for θ in equation (1) to obtain:

$$d = \frac{0.350\,\text{m}}{\tan\left[\sin^{-1}\left(\frac{u}{v}\right)\right]}$$

Substitute numerical values and evaluate d:

$$d = \frac{0.350\,\text{m}}{\tan\left[\sin^{-1}\left(\frac{u}{1.25u}\right)\right]} = \boxed{26.3\,\text{cm}}$$

99 •• A column of precision marchers keeps in step by listening to the band positioned at the head of the column. The beat of the music is for 100 paces/min. A television camera shows that only the marchers at the front and the rear of the column are actually in step. The marchers in the middle section are striding forward with the left foot when those at the front and rear are striding forward with the right foot. The marchers are so well trained, however, that they are all certain that they are in proper step with the music. How long is the column?

Picture the Problem The source of the problem is that it takes a finite time for the sound to travel from the front of the line of marchers to the back. We can use the given data to determine the time required for the beat to reach the marchers in the back of the column and then use this time and the speed of sound to find the length of the column.

Express the length of the column in terms of the speed of sound and the time required for the beat to travel the length of the column:

$$L = v\Delta t$$

Calculate the time for the sound to travel the length of the column:

$$\Delta t = \frac{1}{100}\,\text{min} = 0.600\,\text{s}$$

Substitute numerical values and evaluate L:

$$L = (343\,\text{m/s})(0.600\,\text{s}) = \boxed{206\,\text{m}}$$

100 •• A bat flying toward a stationary obstacle at 12.0 m/s emits brief, high-frequency sound pulses at a repetition frequency of 80.0 Hz. What is the interval between the arrival times of the reflected pulses heard by the bat?

Picture the Problem The interval between the arrival times of the reflected pulses heard by the bat is the reciprocal of the frequency of the reflected pulses. We can use $f_\text{r} = \frac{v \pm u_\text{r}}{v \pm u_\text{s}} f_\text{s}$ to relate the frequency of the reflected pulses to the speed of the bat and the frequency it emits.

Relate the interval between the arrival times of the echo pulses heard by the bat to frequency of the reflected pulses:

$$\Delta t = \frac{1}{f_{\text{r}}}$$

Relate the frequency of the pulses received by the bat to its speed and the frequency it emits:

$$f_{\text{r}} = \frac{v \pm u_{\text{r}}}{v \pm u_{\text{s}}} f_{\text{s}} = \frac{v + u_{\text{r}}}{v - u_{\text{s}}} f_{\text{s}} = \frac{1 + \frac{u_{\text{r}}}{v}}{1 - \frac{u_{\text{s}}}{v}} f_{\text{s}}$$

Substitute for f_{r} to obtain:

$$\Delta t = \frac{1 - \frac{u_{\text{s}}}{v}}{\left(1 + \frac{u_{\text{r}}}{v}\right) f_{\text{s}}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{1 - \frac{12.0\,\text{m/s}}{343\,\text{m/s}}}{\left(1 + \frac{12.0\,\text{m/s}}{343\,\text{m/s}}\right)\left(80.0\,\text{s}^{-1}\right)} = \boxed{11.7\,\text{ms}}$$

101 •• Laser ranging to the moon is done routinely to accurately determine the Earth–moon distance. However, to determine the distance accurately, corrections must be made for the average speed of light in Earth's atmosphere, which is 99.997 percent of the speed of light in vacuum. Assuming that Earth's atmosphere is 8.00 km high, estimate the length of the correction.

Picture the Problem Let d be the distance to the moon, h be the height of Earth's atmosphere, and v be the average speed of light in Earth's atmosphere. We can express d', the distance measured when Earth's atmosphere is ignored, in terms of the time for a pulse of light to make a round-trip from Earth to the moon and solve this equation for the length of correction $d' - d$.

Express the roundtrip time for a pulse of light to reach the moon and return:

$$t = t_{\text{Earth's atmosphere}} + t_{\text{out of Earth's atmosphere}} = 2\frac{h}{v} + 2\frac{d-h}{c}$$

Express the "measured" distance d' when we do not account for the atmosphere:

$$d' = \frac{1}{2}ct = \frac{1}{2}c\left(2\frac{h}{v} + 2\frac{d-h}{c}\right) = \frac{c}{v}h + d - h$$

Solve for the length of correction $d' - d$:

$$d' - d = h\left(\frac{c}{v} - 1\right)$$

Substitute numerical values and evaluate $d' - d$:

$$d' - d = (8.00\,\text{km})\left(\frac{c}{0.99997c} - 1\right)$$
$$\approx \boxed{0.2\,\text{m}}$$

Remarks: This is larger than the accuracy of the measurements, which is about 3 to 4 cm.

102 •• A tuning fork attached to a taut string generates transverse waves. The vibration of the fork is perpendicular to the string. Its frequency is 400 Hz and the amplitude of its oscillation is 0.50 mm. The string has a linear mass density of 0.010 kg/m and is under a tension of 1.0 kN. Assume that there are no waves reflected at the far end of the string. (*a*) What are the period and frequency of waves on the string? (*b*) What is the speed of the waves? (*c*) What are the wavelength and wave number? (*d*) What is a suitable wave function for the waves on the string? (*e*) What is the maximum speed and acceleration of a point on the string? (*f*) At what minimum average rate must energy be supplied to the fork to keep it oscillating at a steady amplitude?

Picture the Problem (*a*) The frequency of the waves on the string is the same as the frequency of the tuning fork and their period is the reciprocal of the frequency. (*b*) We can find the speed of the waves from the tension in the string and its linear density. (*c*) The wavelength can be determined from the frequency and the speed of the waves and the wave number from its definition. (*d*) The general form of the wave function for waves on a string is $y(x,t) = A\sin(kx \pm \omega t)$, so, once we know k and ω, because A is given, we can write a suitable wave function for the waves on this string. (*e*) The maximum speed and acceleration of a point on the string can be found from the angular frequency and amplitude of the waves. (*f*) Finally, we can use $P_{\text{av}} = \frac{1}{2}\mu\omega^2 A^2 v$ to find the minimum average rate at which energy must be supplied to the tuning fork to keep it oscillating with a steady amplitude.

(*a*) The frequency of the waves on the string is the same as the frequency of the tuning fork:

$$f = \boxed{400\,\text{Hz}}$$

The period of the waves on the wire is the reciprocal of their frequency:

$$T = \frac{1}{f} = \frac{1}{400\,\text{s}^{-1}} = \boxed{2.50\,\text{ms}}$$

(*b*) Relate the speed of the waves to the tension in the string and its linear density:

$$v=\sqrt{\frac{F_{\mathrm{T}}}{\mu}}=\sqrt{\frac{1.0\,\mathrm{kN}}{0.010\,\mathrm{kg/m}}}=316.2\,\mathrm{m/s}$$
$$=\boxed{0.32\,\mathrm{km/s}}$$

(*c*) Use the relationship between the wavelength, speed and frequency of a wave to find λ:

$$\lambda=\frac{v}{f}=\frac{316.2\,\mathrm{m/s}}{400\,\mathrm{s^{-1}}}=79.05\,\mathrm{cm}$$
$$=\boxed{79\,\mathrm{cm}}$$

Using its definition, express and evaluate the wave number:

$$k=\frac{2\pi}{\lambda}=\frac{2\pi}{79.05\times10^{-2}\,\mathrm{m}}=7.95\,\mathrm{m^{-1}}$$
$$=\boxed{7.9\,\mathrm{m^{-1}}}$$

(*d*) Determine the angular frequency of the waves:

$$\omega=2\pi f=2\pi\left(400\,\mathrm{s^{-1}}\right)=2.51\times10^{3}\,\mathrm{s^{-1}}$$

Substitute for A, k, and ω in the general form of the wave function to obtain:

$$y(x,t)=\boxed{(0.50\,\mathrm{mm})\sin\left[\left(7.9\,\mathrm{m^{-1}}\right)x-\left(2.51\times10^{3}\,\mathrm{s^{-1}}\right)t\right]}$$

(*e*) Relate the maximum speed of a point on the string to the amplitude of the waves and the angular frequency of the tuning fork:

$$v_{\mathrm{max}}=A\omega$$
$$=\left(0.50\times10^{-3}\,\mathrm{m}\right)\left(2.51\times10^{3}\,\mathrm{s^{-1}}\right)$$
$$=\boxed{1.3\,\mathrm{m/s}}$$

Express the maximum acceleration of a point on the string in terms of the amplitude of the waves and the angular frequency of the tuning fork:

$$a_{\mathrm{max}}=A\omega^{2}$$
$$=\left(0.50\times10^{-3}\,\mathrm{m}\right)\left(2.51\times10^{3}\,\mathrm{s^{-1}}\right)^{2}$$
$$=\boxed{3.2\,\mathrm{km/s^{2}}}$$

(*f*) Express the minimum average power required to keep the tuning fork oscillating at a steady amplitude in terms of the linear density of the string, the amplitude of its vibrations, and the speed of the waves on the string:

$$P_{\mathrm{av}}=\tfrac{1}{2}\mu\omega^{2}A^{2}v$$

Substitute numerical values and evaluate P_{av}:

$$P_{av} = \tfrac{1}{2}(0.010\,\text{kg/m})(2.51\times10^{3}\,\text{s}^{-1})^{2}(0.50\times10^{-3}\,\text{m})^{2}(316\,\text{m/s}) = \boxed{2.5\,\text{W}}$$

103 ••• A long rope with a mass per unit length of 0.100 kg/m is under a constant tension of 10.0 N. A motor drives one end of the rope with transverse simple harmonic motion at 5.00 cycles per second and an amplitude of 40.0 mm. (*a*) What is the wave speed? (*b*) What is the wavelength? (*c*) What is the maximum transverse linear momentum of a 1.00-mm segment of the rope? (*d*) What is the maximum net force on a 1.00-mm segment of the rope?

Picture the Problem Let Δm represent the mass of the segment of length Δx = 1.00 mm. We can find the wave speed from the given data for the tension in the rope and its linear density. The wavelength can be found from $v = f\lambda$. We'll use the definition of linear momentum to find the maximum transverse linear momentum of the 1-mm segment and apply Newton's second law to the segment to find the maximum net force on it.

(*a*) Find the wave speed from the tension and linear density:

$$v = \sqrt{\frac{F_T}{\mu}} = \sqrt{\frac{10.0\,\text{N}}{0.100\,\text{kg/m}}} = \boxed{10.0\,\text{m/s}}$$

(*b*) Express the wavelength in terms of the speed and frequency of the wave:

$$\lambda = \frac{v}{f} = \frac{10.0\,\text{m/s}}{5.00\,\text{s}^{-1}} = \boxed{2.00\,\text{m}}$$

(*c*) Relate the maximum transverse linear momentum of the 1.00-mm segment to the maximum transverse speed of the wave:

$$p_{max} = \Delta m v_{max} = \mu\Delta x A\omega = 2\pi f\mu\Delta x A$$

Substitute numerical values and evaluate p_{max}:

$$\begin{aligned} p_{max} &= 2\pi(5.00\,\text{s}^{-1})(0.100\,\text{kg/m}) \\ &\quad\times(1.00\times10^{-3}\,\text{m})(0.0400\,\text{m}) \\ &= 1.257\times10^{-4}\,\text{kg}\cdot\text{m/s} \\ &= \boxed{1.26\times10^{-4}\,\text{kg}\cdot\text{m/s}} \end{aligned}$$

(*d*) The maximum net force acting on the segment is the product of the mass of the segment and its maximum acceleration:

$$\begin{aligned} F_{max} &= \Delta m a_{max} = \mu\Delta x A\omega^{2} = \omega p_{max} \\ &= 2\pi f p_{max} \end{aligned}$$

Substitute numerical values and evaluate F_{max}:

$$F_{max} = 2\pi\left(5.00\,\mathrm{s}^{-1}\right)\left(1.257\times10^{-4}\,\mathrm{kg\cdot m/s}\right) = \boxed{3.95\,\mathrm{mN}}$$

104 ••• In this problem, you will derive an expression for the potential energy of a segment of a string carrying a traveling wave (Figure 15-34). The potential energy of a segment equals the work done by the tension in stretching the string, which is $\Delta U = F_T(\Delta\ell - \Delta x)$, where F_T is the tension, $\Delta\ell$ is the length of the stretched segment, and Δx is its original length. (*a*) Use the binomial expansion to show that $\Delta\ell - \Delta x \approx \frac{1}{2}(\Delta y/\Delta x)^2\Delta x$, and therefore $\Delta U \approx \frac{1}{2}F_T\left(\frac{\Delta y}{\Delta x}\right)^2\Delta x$.
(*b*) Compute $\partial y/\partial x$ from the wave function $y(x,t) = A\sin(kx-\omega t)$ (Equation 15-15) and show that $\Delta U \approx \frac{1}{2}F_T A^2k^2\cos^2(kx-\omega t)\Delta x$.

Picture the Problem We can follow the step-by-step instructions outlined above to obtain the given expressions for ΔU.

(*a*) Express the potential energy of a segment of the string:

$$\Delta U = F_T(\Delta\ell - \Delta x)$$

For $\Delta y/\Delta x \ll 1$:

$$\Delta\ell = \Delta x\left[1+\tfrac{1}{2}\left(\frac{\Delta y}{\Delta x}\right)^2\right]$$

and

$$\Delta\ell - \Delta x = \Delta x\left[1+\tfrac{1}{2}\left(\frac{\Delta y}{\Delta x}\right)^2\right] - \Delta x = \boxed{\tfrac{1}{2}\left(\frac{\Delta y}{\Delta x}\right)^2\Delta x}$$

Substitute to obtain:

$$\Delta U = F_T\left[\tfrac{1}{2}\left(\frac{\Delta y}{\Delta x}\right)^2\right] = \boxed{\tfrac{1}{2}F_T\left(\frac{\Delta y}{\Delta x}\right)^2\Delta x}$$

(*b*) Differentiate $y(x,t) = A\sin(kx-\omega t)$ to obtain:

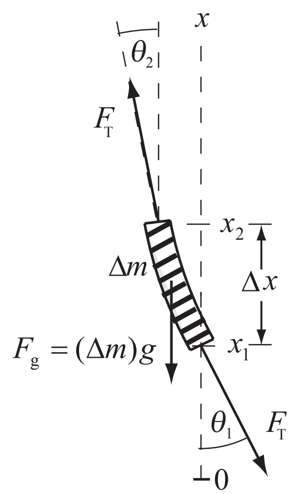
$$\frac{\partial y}{\partial x} = kA\cos(kx-\omega t)$$

Approximate $\Delta y/\Delta x$ by $\partial y/\partial x$ and substitute in our result from Part (*a*):

$$\Delta U = \tfrac{1}{2}F_T\left(kA\cos(kx-\omega t)\right)^2\Delta x = \boxed{\tfrac{1}{2}F_T A^2k^2\Delta x\cos^2(kx-\omega t)}$$

105 ••• One end of a heavy, 3.00-m-long rope is attached to a high ceiling and the rest of the rope is allowed to hang freely. Show that transverse waves on the rope must follow the equation $\dfrac{\partial}{\partial x}\left(x\dfrac{\partial y}{\partial x}\right)=\dfrac{1}{g}\left(\dfrac{\partial^2 y}{\partial t^2}\right)$ instead of $\dfrac{\partial^2 y}{\partial x^2}=\dfrac{1}{v^2}\dfrac{\partial^2 y}{\partial t^2}$.

Picture the Problem Let the $+x$ direction be straight upward and choose the origin 3.00 m below the ceiling. Let y be the transverse direction in which the rope is displaced. Applying Newton's second law to an element of length of the rope will lead to the given equation, which relates the spatial derivatives of $y(x,t)$ to its time derivatives. We'll consider only small values of the angles θ_1 and θ_2 (see the diagram to the right) between the tangent to the rope and the x axis.



Apply $\sum F_x = ma_x$ to the segment whose mass is Δm and whose length is Δx to obtain:

$$F_T(x_2)\cos\theta_2 - F_T(x_1)\cos\theta_1 - (\Delta m)g = 0$$

Note that the segment is not accelerated vertically.

The mass of the segment is the product of its linear density and length:

$$\Delta m = \mu\Delta x$$

Substituting for Δm yields:

$$F_T(x_2)\cos\theta_2 - F_T(x_1)\cos\theta_1 - g\mu\Delta x = 0 \qquad (1)$$

Apply the small-angle approximation ($\cos\theta = 1$ for $|\theta| << 1$) and let $x_1 = x$ and $x_2 = x_1 + \Delta x$ to obtain:

$$F_T(x_2) - F_T(x_1) - g\mu\Delta x = 0$$

or

$$F_T(x+\Delta x) - F_T(x) = g\mu\Delta x$$

Noting that the tension in the rope is zero at $x = 0$, solve for the tension at x_2:

$$F_T(\Delta x) = g\mu\Delta x \Rightarrow F_T(x_2) = g\mu x_2$$

Using the differential approximation we have:

$$F_T(x_2) = F_T(x_1) + \left(\left. \frac{\partial F_T}{\partial x} \right|_{x=x_1} \right)\Delta x = F_T(x_1) + \frac{\partial F_T}{\partial x_1}\Delta x \qquad (2)$$

where we've written $\frac{\partial F_T}{\partial x_1}$ in place of $\left. \frac{\partial F_T}{\partial x} \right|_{x=x_1}$ in order to be more concise.

Substituting equation (2) in equation (1) yields:

$$F_T(x_1) + \frac{\partial F_T}{\partial x_1}\Delta x - F_T(x_1) - g\mu\Delta x = 0$$

Simplify this equation to obtain:

$$\frac{\partial F_T}{\partial x_1} - g\mu = 0 \qquad (3)$$

The segment moves horizontally, and the net force acting in this direction is:

$$\sum F_y = F_T(x_2)\sin\theta_2 - F_T(x_1)\sin\theta_1$$

Using the small-angle approximation $\sin\theta \approx \tan\theta$ yields:

$$\sum F_y \approx F_T(x_2)\tan\theta_2 - F_T(x_1)\tan\theta_1 = F_T(x_2)\frac{\partial y}{\partial x_2} - F_T(x_1)\frac{\partial y}{\partial x_1} \qquad (4)$$

where we've also used $\tan\theta = \text{slope} = \frac{\partial \text{y}}{\partial \text{x}}$.

Applying the differential approximation gives:

$$\frac{\partial y}{\partial x_2} = \frac{\partial y}{\partial x_1} + \left(\frac{\partial}{\partial x}\frac{\partial y}{\partial x_1} \right)\Delta x = \frac{\partial y}{\partial x_1} + \frac{\partial^2 y}{\partial x_1^2}\Delta x$$

Substituting for $F_T(x_2)$ and $\frac{\partial y}{\partial x_2}$ in equation (4) yields:

$$\sum F_y = \left(F_T(x_1) + \frac{\partial F_T}{\partial x_1}\Delta x \right)\left(\frac{\partial y}{\partial x_1} + \frac{\partial^2 y}{\partial x_1^2}\Delta x \right) - F_T(x_1)\frac{\partial y}{\partial x_1}$$

Expand and simplify this expression to obtain:

$$\sum F_y = F_T(x_1)\frac{\partial y}{\partial x_1} + F_T(x_1)\frac{\partial^2 y}{\partial x_1^2}\Delta x + \frac{\partial F_T}{\partial x_1}\frac{\partial y}{\partial x_1}\Delta x + \frac{\partial F_T}{\partial x_1}\frac{\partial^2 y}{\partial x_1^2}(\Delta x)^2 - F_T(x_1)\frac{\partial y}{\partial x_1}$$
$$\approx F_T(x_1)\frac{\partial^2 y}{\partial x_1^2}\Delta x + \frac{\partial F_T}{\partial x_1}\frac{\partial y}{\partial x_1}\Delta x$$

where we have neglected the term with $(\Delta x)^2$.

Applying $\sum F_y = ma_y$ to our length element yields:

$$F_T(x_1)\frac{\partial^2 y}{\partial x_1^2}\Delta x + \frac{\partial F_T}{\partial x_1}\frac{\partial y}{\partial x_1}\Delta x = \mu\Delta x\frac{\partial^2 y}{\partial t^2}$$

Divide both sides of this equation by Δx to obtain:

$$F_T(x_1)\frac{\partial^2 y}{\partial x_1^2} + \frac{\partial F_T}{\partial x_1}\frac{\partial y}{\partial x_1} = \mu\frac{\partial^2 y}{\partial t^2} \quad (5)$$

Substituting $\mu g x$ for F_T yields:

$$\mu g x\frac{\partial^2 y}{\partial x^2} + \frac{\partial(\mu g x)}{\partial x}\frac{\partial y}{\partial x} = \mu\frac{\partial^2 y}{\partial t^2}$$

where we have dropped the subscript 1 by replacing x_1 with x. This can be done without loss of generality because all the x's in equation (5) are x_1's.

Divide both sides of the equation by μg to obtain:

$$x\frac{\partial^2 y}{\partial x^2} + \frac{\partial y}{\partial x} = \frac{1}{g}\frac{\partial^2 y}{\partial t^2} \quad (6)$$

Note that the expression on the left-hand side of the equation can be written as:

$x\frac{\partial^2 y}{\partial x^2} + \frac{\partial y}{\partial x} = \frac{\partial}{\partial x}\left(x\frac{\partial y}{\partial x}\right)$, a result you can verify by using the chain rule to differentiate the right-hand side of this equation.

Substituting in equation (6) yields:

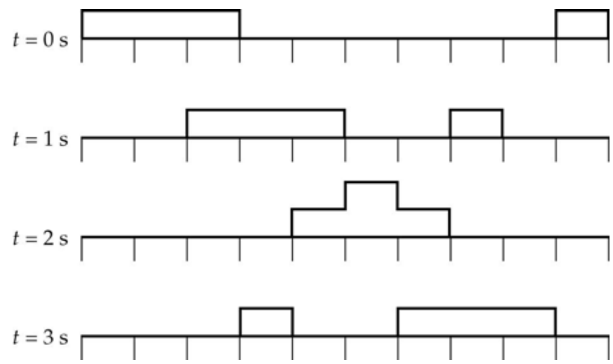
$$\boxed{\frac{\partial}{\partial x}\left(x\frac{\partial y}{\partial x}\right) = \frac{1}{g}\frac{\partial^2 y}{\partial t^2}}$$

Chapter 16
Superposition and Standing Waves

Conceptual Problems

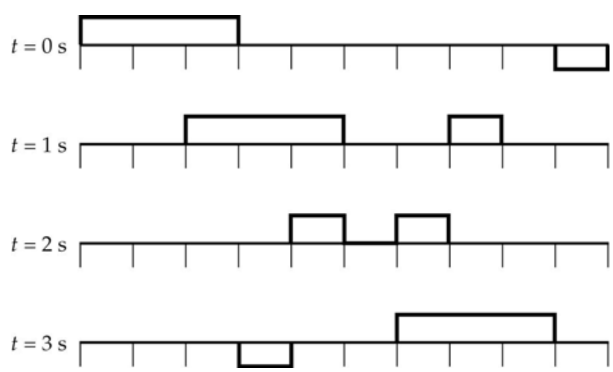
1 • **[SSM]** Two rectangular wave pulses are traveling in opposite directions along a string. At $t = 0$, the two pulses are as shown in Figure 16-29. Sketch the wave functions for $t = 1.0$, 2.0, and 3.0 s.

Picture the Problem We can use the speeds of the pulses to determine their positions at the given times.



2 • Repeat Problem 1 for the case in which the pulse on the right is inverted.

Picture the Problem We can use the speeds of the pulses to determine their positions at the given times.



3 • Beats are produced by the superposition of two harmonic waves if (*a*) their amplitudes and frequencies are equal, (*b*) their amplitudes are the same but their frequencies differ slightly, (*c*) their frequencies differ slightly even if their amplitudes are not equal, (*d*) their frequencies are equal but their amplitudes differ slightly.

Determine the Concept Beats are a consequence of the alternating constructive and destructive interference of waves due to slightly different frequencies. The amplitudes of the waves play no role in producing the beats. $\boxed{(b)\text{ and }(c)}$ are correct.

4 • Two tuning forks are struck and the sounds from each reach your ears at the same time. One sound has a frequency of 256 Hz, and the second sound has a frequency of 258 Hz. The underlying ″hum″ frequency that you hear is (*a*) 2.0 Hz, (*b*) 256 Hz, (*c*) 258 Hz, (*d*) 257 Hz.

Determine the Concept The tone you hear is the average of the frequencies emitted by the vibrating tuning forks; $f_{\text{av}} = \frac{1}{2}(f_1 + f_2) = \frac{1}{2}(256\text{ Hz} + 258\text{ Hz})$ or 257 Hz. Hence $\boxed{(d)}$ is correct.

5 • In Problem 4, the beat frequency is (*a*) 2.0 Hz, (*b*) 256 Hz, (*c*) 258 Hz, (*d*) 257 Hz.

Determine the Concept The beat frequency is the difference between the two frequencies; $f_{\text{beat}} = \Delta f = 258\text{ Hz} - 256\text{ Hz} = 2\text{ Hz}$. Hence $\boxed{(a)}$ is correct.

6 • As a graduate student, you are teaching your first physics lecture while the professor is away. To demonstrate interference of sound waves, you have set up two speakers that are driven coherently and in phase by the same frequency generator on the front desk. Each speaker generates sound with a 2.4–m wavelength. One student in the front row says she hears a very low volume (loudness) of the sound from the speakers compared to the volume of the sound she hears when only one speaker is generating sound. What could be the difference in the distance between her and each of the two speakers? (*a*) 1.2 m, (*b*) 2.4 m, (*c*) 4.8 m, (*d*) You cannot determine the difference in distances from the data given.

Determine the Concept Because the sound reaching her from the two speakers is very low, the sound waves must be interfering destructively (or nearly destructively) and the difference in distance between her position and the two speakers must be an odd multiple of a half wavelength. That is, it must be 1.2 m, 3.6 m, 6.0 m, etc. Hence $\boxed{(a)}$ is correct.

7 • In Problem 6, determine the longest wavelength for which a student would hear ″extra loud″ sound due to constructive interference, assuming this student is located so that one speaker is 3.0 m further from her than the other speaker.

Determine the Concept Because the sound reaching the student from the two speakers is extra loud, the sound waves must be interfering constructively (or nearly constructively) and the difference in distance between the student's position and the two speakers must be an integer multiple of a wavelength. Hence the wavelength of the sound is $\boxed{3.0\text{ m}}$.

8 • Consider standing waves in an organ pipe. True or False:

(*a*) In a pipe open at both ends, the frequency of the third harmonic is three times that of the first harmonic.
(*b*) In a pipe open at both ends, the frequency of the fifth harmonic is five times that of the fundamental.
(*c*) In a pipe that is open at one end and stopped at the other, the even harmonics are not excited.

Explain your choices.

(*a*) True. If ℓ is the length of the pipe and v the speed of sound, the excited harmonics are given by $f_n = n\frac{v}{2\ell}$, where n = 1, 2, 3… Hence the frequency of the third harmonic is three times that of the first harmonic.

(*b*) True. If ℓ is the length of the pipe and v the speed of sound, the excited harmonics are given by $f_n = n\frac{v}{2\ell}$, where n = 1, 2, 3… Hence the frequency of the fifth harmonic is five times that of the first harmonic.

(*c*) True. If ℓ is the length of the pipe and v the speed of sound, the excited harmonics are given by $f_n = n\frac{v}{4\ell}$, where n = 1, 3, 5…

9 • Standing waves result from the superposition of two waves that have (*a*) the same amplitude, frequency, and direction of propagation, (*b*) the same amplitude and frequency and opposite directions of propagation, (*c*) the same amplitude, slightly different frequencies, and the same direction of propagation, (*d*) the same amplitude, slightly different frequencies, and opposite directions of propagation.

Determine the Concept Standing waves are the consequence of the constructive interference of waves that have the same amplitude and frequency but are traveling in opposite directions. $\boxed{(b)}$ is correct.

10 • If you blow air over the top of a fairly large drinking straw you can hear a fundamental frequency due to a standing wave being set up in the straw. What happens to the fundamental frequency, (*a*) if while blowing, you cover the bottom of the straw with your fingertip? (*b*) if while blowing you cut the straw in half with a pair of scissors? (*c*) Explain your answers to Parts (*a*) and (*b*).

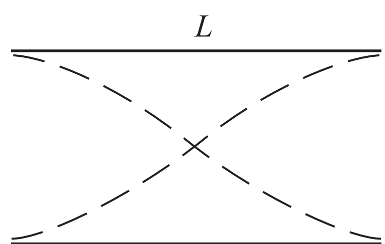
Determine the Concept
(*a*) The fundamental frequency decreases.

(*b*) The fundamental frequency increases.

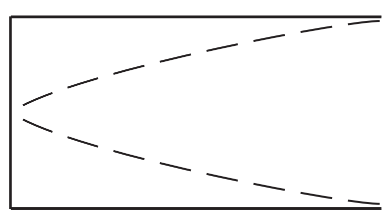
(*c*) **Part (*a*):** The fundamental frequency in a closed-open pipe is half that of an open-open pipe, so the frequency you hear with the bottom covered is half that you hear before you cover the bottom. **Part (*b*):** The fundamental frequencies of all pipes, independently of whether they are open-open or open-closed, varies inversely with the length of the pipe. Hence halving the length of the pipe doubles the fundamental frequency.

11 • **[SSM]** An organ pipe that is open at both ends has a fundamental frequency of 400 Hz. If one end of this pipe is now stopped, the fundamental frequency is (*a*) 200 Hz, (*b*) 400 Hz, (*c*) 546 Hz, (*d*) 800 Hz.

Picture the Problem The first harmonic displacement-wave pattern in an organ pipe open at both ends (open-open) and vibrating in its fundamental mode is represented in part (*a*) of the diagram. Part (*b*) of the diagram shows the wave pattern corresponding to the fundamental frequency for a pipe of the same length L that is stopped. Letting unprimed quantities refer to the open pipe and primed quantities refer to the stopped pipe, we can relate the wavelength and, hence, the frequency of the fundamental modes using $v = f\lambda$.



(*a*)



(*b*)

Express the frequency of the first harmonic in the open-open pipe in terms of the speed and wavelength of the waves:

$$f_1 = \frac{v}{\lambda_1}$$

Relate the length of the open pipe to the wavelength of the fundamental mode:

$$\lambda_1 = 2L$$

Substitute for λ_1 to obtain:

$$f_1 = \frac{v}{2L}$$

Express the frequency of the first harmonic in the closed pipe in terms of the speed and wavelength of the waves:

$$f_1' = \frac{v}{\lambda_1'}$$

Relate the length of the open-closed pipe to the wavelength of it's fundamental mode:

$$\lambda_1' = 4L$$

Substitute for λ_1' to obtain:

$$f_1' = \frac{v}{4L} = \frac{1}{2}\left(\frac{v}{2L}\right) = \frac{1}{2} f_1$$

Substitute numerical values and evaluate f_1':

$$f_1' = \frac{1}{2}(400\,\text{Hz}) = 200\,\text{Hz}$$

and $\boxed{(a)}$ is correct.

12 •• A string fixed at both ends resonates at a fundamental frequency of 180 Hz. Which of the following will reduce the fundamental frequency to 90 Hz? (*a*) Double the tension and double the length. (*b*) Halve the tension and keep the length and the mass per unit length fixed. (*c*) Keep the tension and the mass per unit length fixed and double the length. (*d*) Keep the tension and the mass per unit length fixed and halve the length.

Picture the Problem The frequency of the fundamental mode of vibration is directly proportional to the speed of waves on the string and inversely proportional to the wavelength which, in turn, is directly proportional to the length of the string. By expressing the fundamental frequency in terms of the length L of the string and the tension F in it we can examine the various changes in lengths and tension to determine which would halve it.

Express the dependence of the frequency of the fundamental mode of vibration of the string on its wavelength:

$$f_1 = \frac{v}{\lambda_1}$$

Relate the length of the string to the wavelength of the fundamental mode:

$$\lambda_1 = 2L$$

Substitute for λ_1 to obtain:

$$f_1 = \frac{v}{2L}$$

Express the dependence of the speed of waves on the string on the tension in the string:

$$v = \sqrt{\frac{F_T}{\mu}}$$

Substitute for v in the expression for f_1 to obtain:

$$f_1 = \frac{1}{2L}\sqrt{\frac{F_T}{\mu}}$$

(*a*) Doubling the tension and the length would increase the frequency by a factor of $\sqrt{2}/2$.

(*b*) Halving the tension and keeping the length and the mass per unit length fixed would decrease the frequency by a factor of $1/\sqrt{2}$.

(*c*) Keeping the tension and the mass per unit length fixed and doubling the length will have the fundamental frequency. $\boxed{(c)}$ is correct.

(*d*) Keeping the tension and the mass per unit length fixed and halving the length would double the frequency.

13 •• [SSM] Explain how you might use the resonance frequencies of an organ pipe to estimate the temperature of the air in the pipe.

Determine the Concept You could measure the lowest resonant frequency f and the length L of the pipe. Assuming the end corrections are negligible, the wavelength equals $4L$ if the pipe is stopped at one end, and is $2L$ if the pipe is open at both ends. Then use $v = f\lambda$ to find the speed of sound at the ambient temperature. Finally, use $v = \sqrt{\gamma RT/M}$ (Equation 15-5), where γ = 1.4 for a diatomic gas such as air, M is the molar mass of air, R is the universal gas constant, and T is the absolute temperature, to estimate the temperature of the air.

14 •• In the fundamental standing-wave pattern of a organ pipe stopped at one end, what happens to the wavelength, frequency, and speed of the sound needed to create the pattern if the air in the pipe becomes significantly colder? Explain your reasoning.

Determine the Concept The pipe will contract as the air in it becomes significantly colder, and so the wavelength (equal to $4L$) will decrease as well. This effect, however, is negligible compared to the decrease in the speed of sound (recall that the speed of sound in a gas depends on the square root of the absolute temperature). Because $v = f\lambda$ and v decreases with λ remaining approximately constant, f must decrease.

15 •• [SSM] (*a*) When a guitar string is vibrating in its fundamental mode, is the wavelength of the sound it produces in air typically the same as the wavelength of the standing wave on the string? Explain. (*b*) When an organ pipe is in any one of its standing wave modes, is the wavelength of the traveling sound wave it produces in air typically the same as the wavelength of the standing sound wave in the pipe? Explain.

Determine the Concept

(*a*) No; the wavelength of a wave is related to its frequency and speed of propagation ($\lambda = v/f$). The frequency of the plucked string will be the same as the frequency of the wave it produces in air, but the speeds of the waves depend on the media in which they are propagating. Because the velocities of propagation differ, the wavelengths will not be the same.

(*b*) Yes. Because both the standing waves in the pipe and the traveling waves have the same speed and frequency, they must have the same wavelength.

16 •• Figure 16-30 is a photograph of two pieces of very finely woven silk placed one on top of the other. Where the pieces overlap, a series of light and dark lines are seen. This moiré pattern can also be seen when a scanner is used to copy photos from a book or newspaper. What causes the moiré pattern, and how is it similar to the phenomenon of interference?

Determine the Concept The light is being projected up from underneath the silk, so you will see light where there is a gap and darkness where two threads overlap. Because the two weaves have almost the same spatial period but not exactly identical (because the two are stretched unequally), there will be places where, for large sections of the cloth, the two weaves overlap in phase, leading to brightness, and large sections where the two overlap 90° out of phase (that is, thread on gap and vice versa) leading to darkness. This is exactly the same idea as in the interference of two waves.

17 •• When a musical instrument consisting of drinking glasses, each partially filled to a different height with water, is struck with a small mallet, each glass produces a different frequency of sound wave. Explain how this instrument works.

Determine the Concept Standing sound waves are produced in the air columns above the water. The resonance frequency of the air columns depends on the length of the air column, which depends on how much water is in the glass.

18 •• During an organ recital, the air compressor that drives the organ pipes suddenly fails. An enterprising physics student in the audience tries to help by replacing the compressor with a tank of a pressurized tank of nitrogen gas. What effect, if any, will the nitrogen gas have on the frequency output of the organ pipes? What effect, if any, would helium gas have on the frequency output of the organ pipes?

Picture the Problem We can use $v = f\lambda$ to relate the frequency of the sound waves in the organ pipes to the speed of sound in air, nitrogen, and helium. We can use $v = \sqrt{\gamma RT/M}$ to relate the speed of sound, and hence its frequency, to the properties of the three gases.

Express the frequency of a given note as a function of its wavelength and the speed of sound:

$$f = \frac{v}{\lambda}$$

Relate the speed of sound to the absolute temperature and the molar mass of the gas used in the organ:

$$v = \sqrt{\frac{\gamma RT}{M}}$$

where γ depends on the kind of gas, R is a constant, T is the absolute temperature, and M is the molar mass.

Substitute for v to obtain:

$$f = \frac{1}{\lambda}\sqrt{\frac{\gamma RT}{M}}$$

For air in the organ pipes we have:

$$f_{\text{air}} = \frac{1}{\lambda}\sqrt{\frac{\gamma_{\text{air}} RT}{M_{\text{air}}}} \quad (1)$$

When nitrogen is in the organ pipes:

$$f_{N_2} = \frac{1}{\lambda}\sqrt{\frac{\gamma_{N_2} RT}{M_{N_2}}} \quad (2)$$

Express the ratio of equation (2) to equation (1) and solve for f_{N_2}:

$$\frac{f_{N_2}}{f_{air}} = \sqrt{\frac{\gamma_{N_2}}{\gamma_{air}}\frac{M_{air}}{M_{N_2}}}$$

and

$$f_{N_2} = f_{air}\sqrt{\frac{\gamma_{N_2}}{\gamma_{air}}\frac{M_{air}}{M_{N_2}}}$$

Because $\gamma_{N_2} = \gamma_{air}$ and $M_{air} > M_{N_2}$:

$$f_{N_2} > f_{air}$$

That is,

$\boxed{f \text{ will increase for each organ pipe.}}$

Note, however, that because M_{air} is not very much greater than M_{N_2}, the change in frequency will not be very great.

If helium were used, we'd have:

$$f_{He} = f_{air}\sqrt{\frac{\gamma_{He}}{\gamma_{air}}\frac{M_{air}}{M_{He}}}$$

Because $\gamma_{He} > \gamma_{air}$ and $M_{air} >> M_{He}$, $f_{He} >> f_{air}$ and the effect will be even more pronounced.

19 •• The constant γ for helium (and all monatomic gases) is 1.67. If a man inhales helium and then speaks, his voice has a high-pitch and becomes cartoon-like. Why?

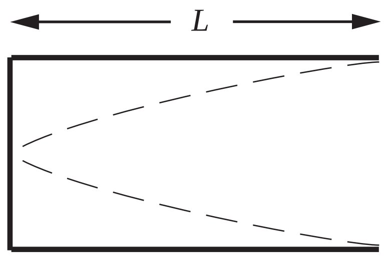
Determine the Concept The wavelength is determined mostly by the resonant cavity of the mouth; the frequency of sounds he makes is equal to the wave speed divided by the wavelength. Because $v_{He} > v_{air}$ (see Equation 15-5), the resonance frequency is higher if helium is the gas in the cavity.

Estimation and Approximation

20 • It is said that a powerful opera singer can hit a high note with sufficient intensity to shatter an empty wine glass by causing the air in it to resonate at the frequency of her voice. Estimate the frequency necessary to obtain a standing wave in an 8.0-cm-high glass. (The 8.0 cm does not include the height of the stem.) Approximately how many octaves above middle C (262 Hz) is this? *Hint: To go up one octave means to double the frequency.*

Picture the Problem If you model the wine glass as a half-open (closed-open) cylinder (shown below on its side), then, knowing the speed of sound in air and

the relationship between the height of the wine glass and the wavelength of its fundamental (1st harmonic) frequency, you can find the fundamental frequency with which it resonates using the relationship $v = f\lambda$. The diagram shows the displacement-amplitude pattern for the 1st harmonic wave pattern. Note that there is a displacement node at the bottom of the wine glass and a displacement antinode at the top of the wine glass. Note further that, in reality, the displacement antinode is a short distance to the right of the open end of the wine glass.



The fundamental frequency is related to the wavelength of the sound in the wine glass according to:

$$f_1 = \frac{v}{\lambda_1}$$

Using the diagram, determine the wavelength of the fundamental mode:

$$L = \tfrac{1}{4}\lambda_1 \Rightarrow \lambda_1 = 4L$$

Substituting for λ_1 yields:

$$f_1 = \frac{v}{4L}$$

Substitute numerical values and evaluate f_1:

$$f_1 = \frac{343\ \text{m/s}}{4(8.0\ \text{cm})} = 1.072\ \text{kHz} = \boxed{1.1\ \text{kHz}}$$

Because the frequencies 262 Hz, 524 Hz, and 1024 Hz are 2^0, 2^1, and 2^2 times 262 Hz, 1.1 kHz is approximately $\boxed{\text{2 octaves}}$ above 262 Hz.

21 • Estimate how accurately you can tune a piano string to a tuning fork of known frequency using only your ears, the tuning fork and a wrench. Explain your answer.

Determine the Concept If you do not hear beats for the entire time the string and the tuning fork are vibrating, you can be sure that their frequencies, while not exactly the same, are very close. If the sounds of the vibrating string and the tuning fork last for 10 s, it follows that the beat frequency is less than 0.1 Hz. Hence, the frequencies of the vibrating string and the tuning fork are within 0.1 Hz of each other.

22 •• The shortest pipes used in organs are about 7.5 cm long. (*a*) Estimate the fundamental frequency of a pipe this long that is open at both ends. (*b*) For such a pipe, estimate the harmonic number *n* of the highest-frequency harmonic that is within the audible range. (The audible range of human hearing is about 20 to 20,000 Hz.)

Picture the Problem We can use $v = f_1\lambda_1$ to express the resonance frequencies in the organ pipes in terms of their wavelengths and $L = n\frac{\lambda_n}{2},\ n = 1, 2, 3, \ldots$ to relate the length of the pipes to the resonance wavelengths.

(*a*) Relate the fundamental frequency of the pipe to its wavelength and the speed of sound:

$$f_1 = \frac{v}{\lambda_1}$$

Express the condition for constructive interference in a pipe that is open at both ends:

$$L = n\frac{\lambda_n}{2},\ n = 1, 2, 3, \ldots \qquad (1)$$

Solve for λ_1:

$$\lambda_1 = 2L \Rightarrow f_1 = \frac{v}{2L}$$

Substitute numerical values and evaluate f_1:

$$f_1 = \frac{343\,\text{m/s}}{2\left(7.5\times10^{-2}\,\text{m}\right)} = 2.29\,\text{kHz} = \boxed{2.3\,\text{kHz}}$$

(*b*) Relate the resonance frequencies of the pipe to their wavelengths and the speed of sound:

$$f_n = \frac{v}{\lambda_n}$$

Solve equation (1) for λ_n:

$$\lambda_n = \frac{2L}{n} \Rightarrow f_n = n\frac{v}{2L}$$

Substitute numerical values to obtain:

$$f_n = n\frac{343\,\text{m/s}}{2\left(7.5\times10^{-2}\,\text{m}\right)} = n\left(2.29\,\text{kHz}\right)$$

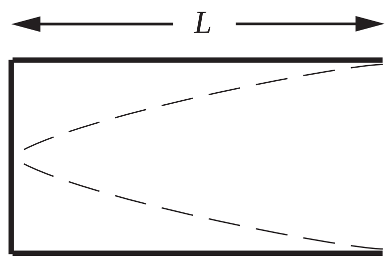
Set $f_n = 20$ kHz and evaluate *n*:

$$n = \frac{20\,\text{kHz}}{2.29\,\text{kHz}} = 8.7$$

The eighth harmonic is within the range defined as audible. The ninth harmonic might be heard by a person with very good hearing.

23 •• Estimate the resonant frequencies that are in the audible range of human hearing of the human ear canal. Treat the canal as an air column open at one end, stopped at the other end, and with a length of 1.00 in. How many resonant frequencies lie in this range? Human hearing has been found experimentally to be the most sensitive at frequencies of about 3, 9 and 15 kHz. How do these frequencies compare to your calculations?

Picture the Problem If you model the human ear canal as an open-stopped column, then, knowing the speed of sound in air and the relationship between the depth of the ear canal and the wavelength of its fundamental (1st harmonic) frequency, you can find the fundamental frequency with which it resonates using the relationship $v = f\lambda$. The diagram shows the displacement-amplitude pattern for the 1st harmonic wave pattern.



The frequencies at which our model ear will resonate are given by:

$$f_n = n\frac{v}{4L}, n = 1,3,5,...$$

Solving for n yields:

$$n = \frac{4Lf_n}{v}$$

The approximate upper limit for a human ear is 20 kHz. Setting f_n equal to 20 kHz and assuming that the temperature of the air in the ear canal is 20°C yields :

$$n = \frac{4\left(1.00\text{ in}\times\frac{2.54\text{ cm}}{\text{in}}\right)(20\text{ kHz})}{343\text{ m/s}} = 5.92 \approx 5$$

and

$\boxed{3}$ resonant frequencies lie within the range of normal human hearing.

The frequencies that lie within the range of human hearing correspond to $n = 1, 3,$ and 5 are:

$$f_1 = \frac{343\ \text{m/s}}{4(2.54\ \text{cm})} \approx 3.38\ \text{kHz},$$

$$f_3 = 3\left(\frac{343\ \text{m/s}}{4(2.54\ \text{cm})}\right) \approx 10.1\ \text{kHz},$$

and

$$f_5 = 5\left(\frac{343\ \text{m/s}}{4(2.54\ \text{cm})}\right) \approx 16.9\ \text{kHz}$$

The calculated frequencies agree with the observed frequencies to within 14%.

Superposition and Interference

24 • Two harmonic waves traveling on a string in the same direction both have a frequency of 100 Hz, a wavelength of 2.0 cm, and an amplitude of 0.020 m. In addition, they overlap each other. What is the amplitude of the resultant wave if the original waves differ in phase by (*a*) $\pi/6$ and (*b*) $\pi/3$?

Picture the Problem We can use $A = 2y_0 \cos\frac{1}{2}\delta$ to find the amplitude of the resultant wave.

(*a*) Evaluate the amplitude of the resultant wave when $\delta = \pi/6$:

$$A = 2y_0 \cos\tfrac{1}{2}\delta = 2(0.020\ \text{m})\cos\frac{1}{2}\left(\frac{\pi}{6}\right)$$

$$= \boxed{3.9\ \text{cm}}$$

(*b*) Proceed as in (*a*) with $\delta = \pi/3$:

$$A = 2y_0 \cos\tfrac{1}{2}\delta = 2(0.020\ \text{m})\cos\frac{1}{2}\left(\frac{\pi}{3}\right)$$

$$= \boxed{3.5\ \text{cm}}$$

25 • **[SSM]** Two harmonic waves having the same frequency, wave speed and amplitude are traveling in the same direction and in the same propagating medium. In addition, they overlap each other. If they differ in phase by $\pi/2$ and each has an amplitude of 0.050 m, what is the amplitude of the resultant wave?

Picture the Problem We can use $A = 2y_0 \cos\frac{1}{2}\delta$ to find the amplitude of the resultant wave.

Evaluate the amplitude of the resultant wave when $\delta = \pi/2$:

$$A = 2y_0 \cos\tfrac{1}{2}\delta = 2(0.050\ \text{m})\cos\frac{1}{2}\left(\frac{\pi}{2}\right)$$

$$= \boxed{7.1\ \text{cm}}$$

26 • Two audio speakers facing in the same direction oscillate in phase at the same frequency. They are separated by a distance equal to one-third of a wavelength. Point *P* is in front of both speakers, on the line that passes through their centers. The amplitude of the sound at *P* due to either speaker acting alone is *A*. What is the amplitude (in terms of *A*) of the resultant wave at that point?

Picture the Problem The phase shift in the waves generated by these two sources is due to their separation of $\lambda/3$. We can find the phase difference due to the path difference from $\delta = 2\pi\frac{\Delta x}{\lambda}$ and then the amplitude of the resultant wave using $A = 2y_0\cos\frac{1}{2}\delta$.

Evaluate the phase difference δ:

$$\delta = 2\pi\frac{\Delta x}{\lambda} = 2\pi\frac{\lambda/3}{\lambda} = \frac{2}{3}\pi$$

Find the amplitude of the resultant wave:

$$A_{\text{res}} = 2y_0\cos\tfrac{1}{2}\delta = 2A\cos\frac{1}{2}\left(\frac{2}{3}\pi\right)$$

$$= 2A\cos\frac{\pi}{3} = \boxed{A}$$

27 • Two compact sources of sound oscillate in phase with a frequency of 100 Hz. At a point 5.00 m from one source and 5.85 m from the other, the amplitude of the sound from each source separately is *A*. (*a*) What is the phase difference of the two waves at that point? (*b*) What is the amplitude (in terms of *A*) of the resultant wave at that point?

Picture the Problem The phase shift in the waves generated by these two sources is due to a path difference Δx = 5.85 m – 5.00 m = 0.85 m. We can find the phase difference due to this path difference from $\delta = 2\pi\frac{\Delta x}{\lambda}$ and then the amplitude of the resultant wave using $A = 2y_0\cos\frac{1}{2}\delta$.

(*a*) Find the phase difference due to the path difference:

$$\delta = 2\pi\frac{\Delta x}{\lambda}$$

Use $v = f\lambda$ to eliminate λ:

$$\delta = 2\pi\frac{\Delta x}{\frac{v}{f}} = 2\pi f\,\frac{\Delta x}{v}$$

Substitute numerical values and evaluate δ:

$$\delta = 2\pi\left(100\,\text{s}^{-1}\right)\frac{0.85\,\text{m}}{343\,\text{m/s}} = 1.557\,\text{rad}$$

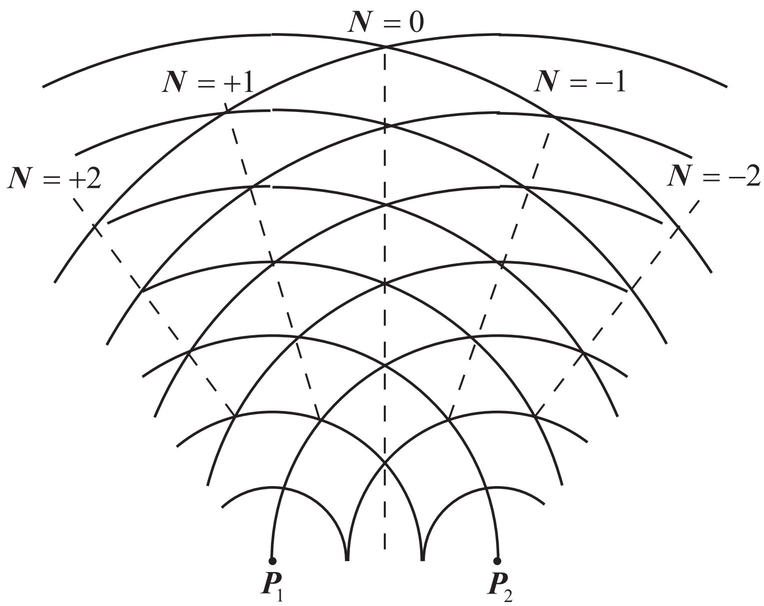
$$= \boxed{89^\circ}$$

(*b*) Relate the amplitude of the resultant wave to the amplitudes of the interfering waves and the phase difference between them:

$$A = 2y_0 \cos\tfrac{1}{2}\delta = 2A\cos\tfrac{1}{2}(1.557)$$
$$= \boxed{1.4A}$$

28 • With a drawing program or a compass, draw circular arcs of radius 1 cm, 2 cm, 3 cm, 4 cm, 5 cm, 6 cm and 7 cm centered at each of two points (P_1 and P_2) a distance d = 3.0 cm apart. Draw smooth curves through the intersections corresponding to points N centimeters farther from P_1 than from P_2 for N = +2, +1, 0, –1 and –2, and label each curve with the corresponding value of N. There are two additional such curves you can draw, one for N = +3 and one for N = –3. If identical sources of coherent in-phase 1.0-cm wavelength waves were placed at points P_1 and P_2, the waves would interfere constructively along each of the smooth curves.

Picture the Problem The following diagram was constructed using a spreadsheet program.



29 • **[SSM]** Two speakers separated by some distance emit sound waves of the same frequency. At some point P, the intensity due to each speaker separately is I_0. The distance from P to one of the speakers is $\frac{1}{2}\lambda$ longer than that from P to the other speaker. What is the intensity at P if (*a*) the speakers are coherent and in phase, (*b*) the speakers are incoherent, and (*c*) the speakers are coherent and 180° out of phase?

Picture the Problem The intensity at the point of interest is dependent on whether the speakers are coherent and on the total phase difference in the waves arriving at the given point. We can use $\delta = 2\pi\dfrac{\Delta x}{\lambda}$ to determine the phase

difference δ, $A=\left|2p_0\cos\frac{1}{2}\delta\right|$ to find the amplitude of the resultant wave, and the fact that the intensity I is proportional to the square of the amplitude to find the intensity at P for the given conditions.

(*a*) Find the phase difference δ:

$$\delta=2\pi\frac{\frac{1}{2}\lambda}{\lambda}=\pi$$

Find the amplitude of the resultant wave:

$$A=\left|2p_0\cos\tfrac{1}{2}\pi\right|=0$$

Because the intensity is proportional to A^2:

$$I=\boxed{0}$$

(*b*) The sources are incoherent and the intensities add:

$$I=\boxed{2I_0}$$

(*c*) The total phase difference is the sum of the phase difference of the sources and the phase difference due to the path difference:

$$\begin{aligned}\delta_{\text{tot}}&=\delta_{\text{sources}}+\delta_{\text{path difference}}\\&=\pi+2\pi\frac{\Delta x}{\lambda}=\pi+2\pi\left(\frac{1}{2}\right)\\&=2\pi\end{aligned}$$

Find the amplitude of the resultant wave:

$$A=\left|2p_0\cos\tfrac{1}{2}(2\pi)\right|=2p_0$$

Because the intensity is proportional to A^2:

$$I=\frac{A^2}{p_0^2}I_0=\frac{(2p_0)^2}{p_0^2}I_0=\boxed{4I_0}$$

30 • Two speakers separated by some distance emit sound waves of the same frequency. At some point P', the intensity due to each speaker separately is I_0. The distance from P' to one of the speakers is one wavelength longer than that from P' to the other speaker. What is the intensity at P if (*a*) the speakers are coherent and in phase, (*b*) the speakers are incoherent, and (*c*) the speakers are coherent and out of phase?

Picture the Problem The intensity at the point of interest is dependent on whether the speakers are coherent and on the total phase difference in the waves arriving at the given point. We can use $\delta = 2\pi \frac{\Delta x}{\lambda}$ to determine the phase difference δ, $A = \left|2p_0 \cos\frac{1}{2}\delta\right|$ to find the amplitude of the resultant wave, and the fact that the intensity is proportional to the square of the amplitude to find the intensity at P for the given conditions.

(*a*) Find the phase difference δ:

$$\delta = 2\pi \frac{\lambda}{\lambda} = 2\pi$$

Find the amplitude of the resultant wave:

$$A = \left|2p_0 \cos\tfrac{1}{2}(2\pi)\right| = 2p_0$$

Because the intensity is proportional to A^2:

$$I = \frac{A^2}{p_0^2} I_0 = \frac{(2p_0)^2}{p_0^2} I_0 = \boxed{4I_0}$$

(*b*) The sources are incoherent and the intensities add:

$$I = \boxed{2I_0}$$

(*c*) The total phase difference is the sum of the phase difference of the sources and the phase difference due to the path difference:

$$\begin{aligned}\delta_{\text{tot}} &= \delta_{\text{sources}} + \delta_{\text{path difference}} \\ &= \pi + 2\pi \frac{\Delta x}{\lambda} = \pi + 2\pi\left(\frac{\lambda}{\lambda}\right) \\ &= 3\pi\end{aligned}$$

Find the amplitude of the resultant wave:

$$A = \left|2p_0 \cos\tfrac{1}{2}(3\pi)\right| = 0$$

Because the intensity is proportional to A^2:

$$I = \boxed{0}$$

31 •• A transverse harmonic wave with a frequency equal to 40.0 Hz propagates along a taut string. Two points 5.00 cm apart are out of phase by $\pi/6$. (*a*) What is the wavelength of the wave? (*b*) At a given point on the string, how much does the phase change in 5.00 ms? (*c*) What is the wave speed?

Picture the Problem (*a*) Let the +*x* direction be the direction of propagation of the wave. We can express the phase difference in terms of the separation of the two points and the wavelength of the wave and solve for λ. (*b*) We can find the phase difference by relating the time between displacements to the period of the wave. (*c*) We can use the relationship between the speed, frequency, and wavelength of a wave to find its velocity.

(*a*) Relate the phase difference to the wavelength of the wave:

$$\delta = 2\pi\frac{\Delta x}{\lambda}$$

Solve for and evaluate λ:

$$\lambda = 2\pi\frac{\Delta x}{\delta} = 2\pi\frac{5.00\,\text{cm}}{\frac{1}{6}\pi} = \boxed{60.0\,\text{cm}}$$

(*b*) The period of the wave is given by:

$$T = \frac{1}{f} = \frac{1}{40.0\,\text{s}^{-1}} = 25.0\,\text{ms}$$

Relate the time between the two displacements to the period of the wave:

$$5.00\,\text{ms} = \frac{1}{5}T$$

The phase difference corresponding to one-fifth of a period is:

$$\delta = \boxed{\frac{2\pi}{5}}$$

(*c*) The wave speed is the product of its frequency and wavelength:

$$v = f\lambda = \left(40.0\,\text{s}^{-1}\right)\left(0.600\,\text{m}\right) = \boxed{24.0\,\text{m/s}}$$

32 •• It is thought that the brain determines the direction of the source of a sound by sensing the phase difference between the sound waves striking the eardrums. A distant source emits sound of frequency 680 Hz. When you are directly facing a sound source there is no phase difference. Estimate the phase difference between the sounds received by your ears when you are facing 90° away from the direction of the source.

Picture the Problem Assume a distance of about 20 cm between your ears. When you rotate your head through 90°, you introduce a path difference of 20 cm. We can apply the equation for the phase difference due to a path difference to determine the change in phase between the sounds received by your ears as you rotate your head through 90°.

Express the phase difference due to the rotation of your head through 90°:

$$\delta = 2\pi \frac{20\,\text{cm}}{\lambda}$$

Because $\lambda = v/f$:

$$\delta = 2\pi f \frac{20\,\text{cm}}{v}$$

Substitute numerical values and evaluate δ:

$$\delta = 2\pi\left(680\,\text{s}^{-1}\right)\frac{20\,\text{cm}}{343\,\text{m/s}} = \boxed{0.79\pi\,\text{rad}}$$

33 •• [SSM] Sound source A is located at $x = 0$, $y = 0$, and sound source B is located at $x = 0$, $y = 2.4$ m. The two sources radiate coherently and in phase. An observer at $x = 15$ m, $y = 0$ notes that as he takes a few steps from $y = 0$ in either the $+y$ or $-y$ direction, the sound intensity diminishes. What is the lowest frequency and the next to lowest frequency of the sources that can account for that observation?

Picture the Problem Because the sound intensity diminishes as the observer moves, parallel to a line through the sources, away from his initial position, we can conclude that his initial position is one at which there is constructive interference of the sound coming from the two sources. We can apply the condition for constructive interference to relate the wavelength of the sound to the path difference at his initial position and the relationship between the velocity, frequency, and wavelength of the waves to express this path difference in terms of the frequency of the sources.

Express the condition for constructive interference at (15 m, 0):

$$\Delta r = n\lambda,\ n = 1, 2, 3, \ldots \qquad (1)$$

The path difference Δr is given by:

$$\Delta r = r_B - r_A$$

Using the Pythagorean theorem, express r_B:

$$r_B = \sqrt{(15\,\text{m})^2 + (2.4\,\text{m})^2}$$

Substitute for r_B to obtain:

$$\Delta r = \sqrt{(15\,\text{m})^2 + (2.4\,\text{m})^2} - 15\,\text{m}$$

Using $v = f\lambda$ and equation (1), express f_n in terms of Δr and n:

$$f_n = n\frac{v}{\Delta r},\ n = 1,2,3,\ldots$$

Substituting numerical values yields:

$$f_n = n\frac{343\text{ m/s}}{\sqrt{(15\text{ m})^2 + (2.4\text{ m})^2} - 15\text{ m}}$$
$$= (1.798\text{ kHz})n = (2\text{ kHz})n$$

Evaluate f_1 and f_2 to obtain:

$$f_1 = \boxed{2\text{ kHz}} \text{ and } f_2 = \boxed{4\text{ kHz}}$$

34 •• Suppose that the observer in Problem 33 finds himself at a point of minimum intensity at $x = 15$ m, $y = 0$. What is then the lowest frequency and the next to lowest frequency of the sources consistent with this observation?

Picture the Problem Because the sound intensity increases as the observer moves, parallel to a line through the sources, away from his initial position, we can conclude that his initial position is one at which there is destructive interference of the sound coming from the two sources. We can apply the condition for destructive interference to relate the wavelength of the sound to the path difference at his initial position and the relationship between the velocity, frequency, and wavelength of the waves to express this path difference in terms of the frequency of the sources.

Express the condition for destructive interference at (15.0 m, 0):

$$\Delta r = n\frac{\lambda}{2},\ n = 1,3,5,... \qquad (1)$$

Express the path difference Δr:

$$\Delta r = r_B - r_A$$

Using the Pythagorean theorem, find r_B:

$$r_B = \sqrt{(15\text{ m})^2 + (2.4\text{ m})^2}$$

Substitute for r_B to obtain:

$$\Delta r = \sqrt{(15\text{ m})^2 + (2.4\text{ m})^2} - 15\text{ m}$$

Using $v = f\lambda$ and equation (1), express f_n in terms of Δr and n:

$$f_n = n\frac{v}{2\Delta r},\ n = 1,3,5,...$$

Substituting numerical values yields:

$$f_n = n\frac{343\text{ m/s}}{2\left(\sqrt{(15\text{ m})^2 + (2.4\text{ m})^2} - 15\text{ m}\right)}$$
$$= (0.8989\text{ kHz})n = (1\text{ kHz})n$$

Evaluate f_1 and f_3 to obtain:

$$f_1 = \boxed{1\text{ kHz}} \text{ and } f_3 = \boxed{3\text{ kHz}}$$

35 •• **[SSM]** Two harmonic water waves of equal amplitudes but different frequencies, wave numbers, and speeds are traveling in the same direction. In addition, they are superposed on each other. The total displacement of the wave can be written as $y(x,t) = A[\cos(k_1x - \omega_1t) + \cos(k_2x - \omega_2t)]$, where $\omega_1/k_1 = v_1$ (the speed of the first wave) and $\omega_2/k_2 = v_2$ (the speed of the second wave). (*a*) Show that $y(x,t)$ can be written in the form $y(x,t) = Y(x, t)\cos(k_{av}x - \omega_{av}t)$, where $\omega_{av} = (\omega_1 + \omega_2)/2$, $k_{av} = (k_1 + k_2)/2$, $Y(x, t) = 2A\cos[(\Delta k/2)x - (\Delta\omega/2)t]$, $\Delta\omega = \omega_1 - \omega_2$, and $\Delta k = k_1 - k_2$. The factor $Y(x, t)$ is called the *envelope* of the wave. (*b*) Let $A = 1.00$ cm, $\omega_1 = 1.00$ rad/s, $k_1 = 1.00\ \text{m}^{-1}$, $\omega_2 = 0.900$ rad/s, and $k_2 = 0.800\text{m}^{-1}$. Using a **spreadsheet program** or **graphing calculator**, make a plot of $y(x,t)$ versus x at $t = 0.00$ s for $0 < x < 5.00$ m. (*c*) Using a **spreadsheet program** or **graphing calculator**, make three plots of $Y(x,t)$ versus x for $-5.00\ \text{m} < x < 5.00$ m on the same graph. Make one plot for $t = 0.00$ s, the second for $t = 5.00$ s, and the third for $t = 10.00$ s. Estimate the speed at which the envelope moves from the three plots, and compare this estimate with the speed obtained using $v_{\text{envelope}} = \Delta\omega/\Delta k$.

Picture the Problem We can use the trigonometric identity

$$\cos A + \cos B = 2\cos\left(\frac{A+B}{2}\right)\cos\left(\frac{A-B}{2}\right)$$

to derive the expression given in (*a*) and the speed of the envelope can be found from the second factor in this expression; i.e., from $\cos[(\Delta k/2)x - (\Delta\omega/2)t]$.

(*a*) Express the amplitude of the resultant wave function $y(x,t)$:

$$y(x,t) = A(\cos(k_1x - \omega_1t) + \cos(k_2x - \omega_2t))$$

Use the trigonometric identity $\cos A + \cos B = 2\cos\left(\frac{A+B}{2}\right)\cos\left(\frac{A-B}{2}\right)$ to obtain:

$$y(x,t) = 2A\left[\cos\frac{k_1x - \omega_1t + k_2x - \omega_2t}{2}\cos\frac{k_1x - \omega_1t - k_2x + \omega_2t}{2}\right]$$

$$= 2A\left[\cos\left(\frac{k_1 + k_2}{2}x - \frac{\omega_1 + \omega_2}{2}t\right)\cos\left(\frac{k_1 - k_2}{2}x + \frac{\omega_2 - \omega_1}{2}t\right)\right]$$

Substitute $\omega_{av} = (\omega_1 + \omega_2)/2$, $k_{av} = (k_1 + k_2)/2$, $\Delta\omega = \omega_1 - \omega_2$ and $\Delta k = k_1 - k_2$ to obtain:

$$y(x,t) = 2A\left[\cos\left(k_{ave}x - \omega_{ave}t\right)\cos\left(\frac{\Delta k}{2}x - \frac{\Delta\omega}{2}t\right)\right]$$

$$= \boxed{Y(x,t)\left[\cos\left(k_{ave}x - \omega_{ave}t\right)\right.}$$

where

$$Y(x,t) = \boxed{2A\cos\left(\frac{\Delta k}{2}x - \frac{\Delta\omega}{2}t\right)}$$

(*b*) A spreadsheet program to calculate $y(x,t)$ between 0 m and 5.00 m at $t = 0.00$ s, follows. The constants and cell formulas used are shown in the table.

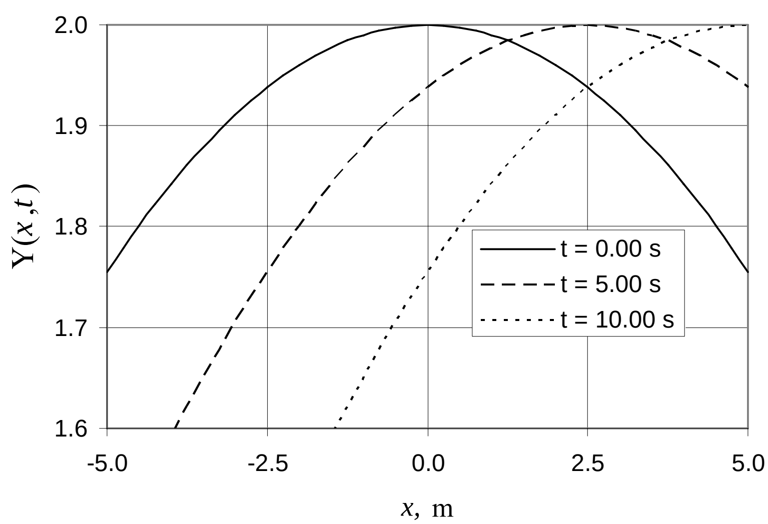
(c) Graphs of $Y(x,t)$ versus x for $-5.00\text{ m} < x < 5.00\text{ m}$ and $t = 0.00$ s, $t = 5.00$ s and $t = 10.00$ s follow:



To estimate the speed of the envelope, we can use its horizontal displacement between $t = 0.00$ s and $t = 5.00$ s:

$$v_{\text{est}} = \frac{\Delta x}{\Delta t} \quad (1)$$

From the graph we note that the wave traveled 2.5 m in 5.00 s:

$$v_{\text{est}} = \frac{2.50\text{ m}}{5.00\text{ s}} = \boxed{50\text{ cm/s}}$$

The speed of the envelope is given by:

$$v_{\text{envelope}} = \frac{\Delta\omega}{\Delta k} = \frac{\omega_1 - \omega_2}{k_1 - k_2}$$

Substitute numerical values and evaluate v_{envelope}:

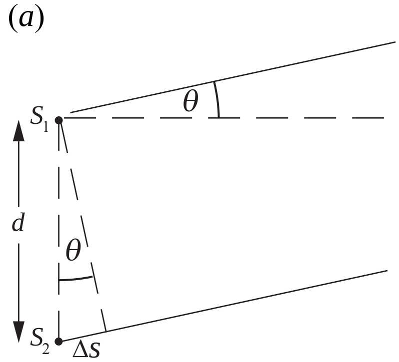
$$v_{\text{envelope}} = \frac{1.00\,\text{rad/s} - 0.900\,\text{rad/s}}{1.00\,\text{m}^{-1} - 0.800\,\text{m}^{-1}} = 50\,\text{cm/s}$$

in agreement with our graphical estimate.

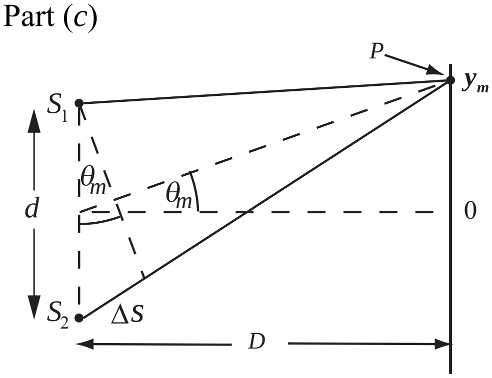
36 •• Two coherent point sources are in phase and are separated by a distance *d*. An interference pattern is detected along a line parallel to the line through the sources and a large distance *D* from the sources, as shown in Figure 16-31. (*a*) Show that the path difference Δs from the two sources to some point on the line at an angle θ is given, approximately, by $\Delta s \approx d\sin\theta$. *Hint: Assume that D >> d, so the lines from the sources to P are approximately parallel* (Figure 16-31*b*). (*b*) Show that the two waves interfere constructively at *P* if $\Delta s = m\lambda$, where $m = 0, 1, 2,...$ (That is, show there is an interference maximum at *P* if $\Delta s = m\lambda$, where $m = 0, 1, 2, ...$) (*c*) Show that the distance y_m from the central maximum (at $y = 0$) to the *m*th interference maximum at *P* is given by $y_m = D\tan\theta_m$, where $d\sin\theta_m = m\lambda$.

Picture the Problem The following diagram shows the two sources separated by a distance *d* and the path difference Δs between the two sources and point *P*. Because the lines from the sources to the distant point are approximately parallel, the triangle shown in the diagram is approximately a right triangle and we can use trigonometry to express Δs in terms of *d* and θ. In Part (*b*), we can use the relationship giving the phase difference due to a path difference to show that the two waves interfere constructively at *P* if $\Delta s = m\lambda$. In Part (*c*) we use the geometry of Figure 16-31*a* to relate y_m to *D* and θ_m.

Part (*a*)



Part (*c*)



(*a*) Using the diagram for Part (*a*), relate Δs to the separation of the sources and the angle θ:

$$\sin\theta \approx \frac{\Delta s}{d} \Rightarrow \Delta s \approx \boxed{d\sin\theta}$$

(*b*) δ is related to Δs through the proportion:

$$\frac{\delta}{2\pi} = \frac{\Delta s}{\lambda} \Rightarrow \Delta s = \frac{\delta\lambda}{2\pi}$$

There will be constructive interference at P provided:

$$\delta = 2\pi m,\ m = 0,1,2,,...$$

Substituting for δ and simplifying yields:

$$\Delta s = \frac{(2\pi m)\lambda}{2\pi} = \boxed{m\lambda,\ m = 0,1,2,,...}$$

(c) Referring to the diagram for Part (c), note that, if $\theta_m << 1$ (equivalently, $d << D$), then $d\sin\theta_m = m\lambda$ and:

$$\tan\theta_m = \frac{y_m}{D} \Rightarrow y_m = \boxed{D\tan\theta_m}$$

37 •• Two sound sources radiating in phase at a frequency of 480 Hz interfere such that maxima are heard at angles of 0º and 23º from a line perpendicular to that joining the two sources. The listener is at a large distance from the line through both sources, and no additional maxima are heard at angles in the range 0° < θ < 23°. Find the separation d between the two sources, and any other angles at which intensity maxima will be heard. (Use the result of Problem 36.)

Picture the Problem Because a maximum is heard at 0° and the sources are in phase, we can conclude that the path difference is 0. Because the next maximum is heard at 23°, the path difference to that position must be one wavelength. We can use the result of Part (a) of Problem 36 to relate the separation of the sources to the path difference and the angle θ. We'll apply the condition for constructive interference to determine the angular locations of other points of maximum intensity in the interference pattern.

Using the result of Part (a) of Problem 36, express the separation of the sources in terms of Δs and θ:

$$d = \frac{\Delta s}{\sin\theta}$$

Because $\Delta s = \lambda$ and $v = f\lambda$:

$$d = \frac{\lambda}{\sin\theta} = \frac{v}{f\sin\theta}$$

Evaluate d with $\Delta s = \lambda$ and $\theta = 23°$:

$$d = \frac{343\ \text{m/s}}{(480\ \text{s}^{-1})\sin 23°} = 1.83\ \text{m} = \boxed{1.8\ \text{m}}$$

Express the condition for additional intensity maxima:

$$d\sin\theta_m = m\lambda$$

where m = 1, 2, 3, …, or

$$\theta_m = \sin^{-1}\left[\frac{m\lambda}{d}\right]$$

Evaluate this expression for $m = 2$:

$$\theta_2 = \sin^{-1}\left[\frac{2(343\,\text{m/s})}{(480\,\text{s}^{-1})(1.83\,\text{m})}\right] = \boxed{51°}$$

Remarks: It is easy to show that, for *m* > 2, the inverse sine function is undefined and that, therefore, there are no additional relative maxima at angles larger than 51°.

38 •• Two loudspeakers are driven in phase by an audio amplifier at a frequency of 600 Hz. The speakers are on the y axis, one at $y = +1.00$ m and the other at $y = -1.00$ m. A listener, starting at $(x, y) = (D, 0)$, where $D >> 2.00$ m, walks in the $+y$ direction along the line $x = D$. (See Problem 36.) (*a*) At what angle θ will she first hear a minimum in the sound intensity? (θ is the angle between the positive x axis and the line from the origin to the listener.) (*b*) At what angle will she first hear a maximum in the sound intensity (after $\theta = 0$)? (*c*) How many maxima can she possibly hear if she keeps walking in the same direction?

Picture the Problem Because the speakers are driven in phase and the path difference is 0 at her initial position, the listener will hear a maximum at (*D*, 0). As she walks along a line parallel to the *y* axis she will hear a minimum wherever it is true that the path difference is an odd multiple of a half wavelength. She will hear an intensity maximum wherever the path difference is an integral multiple of a wavelength. We'll apply the condition for destructive interference in Part (*a*) to determine the angular location of the first minimum and, in Part (*b*), the condition for constructive interference find the angle at which she'll hear the first maximum after the one at 0°. In Part (*c*), we can apply the condition for constructive interference to determine the number of maxima she can hear as keeps walking parallel to the *y* axis.

(*a*) Express the condition for destructive interference:

$$d\sin\theta_m = m\frac{\lambda}{2}$$

where $m = 1, 3, 5, \ldots$, or

$$\theta_m = \sin^{-1}\left(\frac{m\lambda}{2d}\right) = \sin^{-1}\left(\frac{mv}{2fd}\right)$$

Evaluate this expression for $m = 1$:

$$\theta_1 = \sin^{-1}\left[\frac{343\,\text{m/s}}{2(600\,\text{s}^{-1})(2.00\,\text{m})}\right] = \boxed{8.22°}$$

(*b*) Express the condition for additional intensity maxima:

$$d\sin\theta_m = m\lambda$$

where m = 0, 1, 2, 3,…, or

$$\theta_m = \sin^{-1}\left(\frac{m\lambda}{d}\right) = \sin^{-1}\left(\frac{mv}{fd}\right)$$

Evaluate this expression for $m = 1$:

$$\theta_1 = \sin^{-1}\left[\frac{343\,\text{m/s}}{(600\,\text{s}^{-1})(2.00\,\text{m})}\right] = \boxed{16.6°}$$

(*c*) Express the limiting condition on $\sin\theta$:

$$\sin\theta_m = m\frac{\lambda}{d} \leq 1 \Rightarrow m \leq \frac{d}{\lambda} = \frac{fd}{v}$$

Substitute numerical values and evaluate m:

$$m \leq \frac{(600\,\text{s}^{-1})(2.00\,\text{m})}{343\,\text{m/s}} = 3.50$$

Because m must be an integer:

$$m = \boxed{3}$$

39 ••• [SSM] Two sound sources driven in phase by the same amplifier are 2.00 m apart on the y axis, one at $y = +1.00$ m and the other at $y = -1.00$ m. At points large distances from the y axis, constructive interference is heard at at angles with the x axis of $\theta_0 = 0.000$ rad, $\theta_1 = 0.140$ rad and $\theta_2 = 0.283$ rad, and at no angles in between (see Figure 16-31). (*a*) What is the wavelength of the sound waves from the sources? (*b*) What is the frequency of the sources? (*c*) At what other angles is constructive interference heard? (*d*) What is the smallest angle for which the sound waves cancel?

Picture the Problem (*a*) Let d be the separation of the two sound sources. We can express the wavelength of the sound in terms of the d and either of the angles at which intensity maxima are heard. (*b*) We can find the frequency of the sources from its relationship to the speed of the waves and their wavelengths. (*c*) Using the condition for constructive interference, we can find the angles at which intensity maxima are heard. (*d*) We can use the condition for destructive interference to find the smallest angle for which the sound waves cancel.

(*a*) Express the condition for constructive interference:

$$d\sin\theta_m = m\lambda \Rightarrow \lambda = \frac{d\sin\theta_m}{m} \quad (1)$$

where m = 0, 1, 2, 3,…

Evaluate λ for $m = 1$:

$$\lambda = (2.00\,\text{m})\sin(0.140\,\text{rad}) = \boxed{0.279\,\text{m}}$$

(*b*) The frequency of the sound is given by:

$$f=\frac{v}{\lambda}=\frac{343\,\text{m/s}}{0.279\,\text{m}}=\boxed{1.23\,\text{kHz}}$$

(*c*) Solve equation (1) for θ_m:

$$\theta_m=\sin^{-1}\left(\frac{m\lambda}{d}\right)=\sin^{-1}\left[\frac{m(0.279\,\text{m})}{2.00\,\text{m}}\right]$$
$$=\sin^{-1}[(0.1395)m]$$

The table shows the values for θ as a function of m:

m	θ_m
	(rad)
3	$\boxed{0.432}$
4	$\boxed{0.592}$
5	$\boxed{0.772}$
6	$\boxed{0.992}$
7	$\boxed{1.35}$
8	undefined

(*d*) Express the condition for destructive interference:

$$d\sin\theta_m=m\frac{\lambda}{2}$$

where m = 1, 3, 5,…

Solving for θ_m yields:

$$\theta_m=\sin^{-1}\left(m\frac{\lambda}{2d}\right)$$

Evaluate this expression for m = 1:

$$\theta_1=\sin^{-1}\left[\frac{0.279\,\text{m}}{2(2.00\,\text{m})}\right]=\boxed{0.0698\,\text{rad}}$$

40 ••• The two sound sources from Problem 39 are now driven 90º out-of-phase, but at the same frequency as in Problem 39. At what angles are constructive and destructive interference heard?

Picture the Problem The total phase shift in the waves arriving at the points of interest is the sum of the phase shift due to the difference in path lengths from the two sources to a given point and the phase shift due to the sources being out of phase by 90°. From Problem 39 we know that λ = 0.279 m. Using the conditions on the path difference Δx for constructive and destructive interference, we can find the angles at which intensity maxima are heard.

Letting the subscript ″pd″ denote ″path difference″ and the subscript ″s″ the ″sources″, express the total phase shift δ:

$$\delta = \delta_{\text{pd}} + \delta_{\text{s}} = 2\pi\frac{\Delta x}{\lambda} + \frac{\pi}{4}$$

where Δx is the path difference between the two sources and the points at which constructive or destructive interference is heard.

Express the condition for constructive interference:

$$\delta = 2\pi\frac{\Delta x}{\lambda} + \frac{\pi}{4} = 2\pi, 4\pi, 6\pi, \ldots$$

Solve for Δx to obtain:

$$\Delta x = \frac{7}{8}\lambda, \frac{15}{8}\lambda, \frac{23}{8}\lambda, \ldots = \frac{(8m-1)}{8}\lambda$$

where $m = 1, 2, 3, \ldots$

Relate Δx to d to obtain:

$$\Delta x = \frac{(8m-1)}{8}\lambda = d\sin\theta_{\text{c}}$$

where the ″c″ denotes constructive interference.

Solving for θ_{c} yields:

$$\theta_{\text{c}} = \sin^{-1}\left[\frac{(8m-1)\lambda}{8d}\right], m = 1, 2, 3, \ldots$$

The table shows the values for θ_{c} for $m = 1$ to 5:

m	θ_{c}
1	$\boxed{7.01°}$
2	$\boxed{15.2°}$
3	$\boxed{23.6°}$
4	$\boxed{32.7°}$
5	$\boxed{42.8°}$

Express the condition for destructive interference:

$$\delta = 2\pi\frac{\Delta x}{\lambda} + \frac{\pi}{4} = \pi, 3\pi, 5\pi, \ldots$$

Solve for Δx to obtain:

$$\Delta x = \frac{3}{8}\lambda, \frac{11}{8}\lambda, \frac{19}{8}\lambda, \ldots = \frac{(8m-5)}{8}\lambda$$

where $m = 1, 2, 3, \ldots$

Letting ″d″ denotes destructive interference, relate Δx to d to obtain:

$$\Delta x = \frac{(8m-5)}{8}\lambda = d\sin\theta_{\text{d}}$$

Solving for θ_d yields:

$$\theta_d = \sin^{-1}\left[\frac{(8m-5)\lambda}{8d}\right],\ m = 1, 2, 3, \ldots$$

The table shows the values for θ_d for $m = 1$ to 5:

m	θ_d
1	$\boxed{3.00°}$
2	$\boxed{11.1°}$
3	$\boxed{19.3°}$
4	$\boxed{28.1°}$
5	$\boxed{37.6°}$

41 ••• An astronomical radio telescope consists of two antennas separated by a distance of 200 m. Both antennas are tuned to the frequency of 20 MHz. The signals from each antenna are fed into a common amplifier, but one signal first passes through a phase selector that delays its phase by a chosen amount so that the telescope can "look" in different directions (Figure 16-32). When the phase delay is zero, plane radio waves that are incident vertically on the antennas produce signals that add constructively at the amplifier. What should the phase delay be so that signals coming from an angle $\theta = 10°$ with the vertical (in the plane formed by the vertical and the line joining the antennas) will add constructively at the amplifier? *Hint: Radio waves travel at* 3.00×10^8 m/s.

Picture the Problem We can calculate the required phase shift from the path difference and the wavelength of the radio waves using $\delta = 2\pi\frac{\Delta s}{\lambda}$.

Express the phase delay as a function of the path difference and the wavelength of the radio waves:

$$\delta = 2\pi\frac{\Delta s}{\lambda} \quad (1)$$

Find the wavelength of the radio waves:

$$\lambda = \frac{v}{f} = \frac{2.998\times10^8\ \text{m/s}}{20\times10^6\ \text{s}^{-1}} = 15.0\ \text{m}$$

Express the path difference for the signals coming from an angle θ with the vertical:

$$\Delta s = d\sin\theta$$

Substitute numerical values and evaluate Δs:

$$\Delta s = (200\ \text{m})\sin 10° = 34.73\ \text{m}\times\frac{1\lambda}{15.0\ \text{m}}$$
$$= 2.315\lambda = 2\lambda + 0.315\lambda$$

Substitute in equation (1) and evaluate δ:

$$\delta = 2\pi \frac{0.315\lambda}{\lambda} \approx \boxed{2.0\,\text{rad}}$$

Beats

42 • When two tuning forks are struck simultaneously, 4.0 beats per second are heard. The frequency of one fork is 500 Hz. (*a*) What are the possible values for the frequency of the other fork? (*b*) A piece of wax is placed on the 500-Hz fork to lower its frequency slightly. Explain how the measurement of the new beat frequency can be used to determine which of your answers to Part (*a*) is the correct frequency of the second fork.

Picture the Problem The beat frequency is the difference between the frequencies of the two tuning forks. Let $f_1 = 500$ Hz.

(*a*) Express the relationship between the beat frequency of the frequencies of the two tuning forks:

$$f_2 = f_1 \pm \Delta f$$
$$= 500\,\text{Hz} \pm 4\,\text{Hz}$$

Solving for f_2 yields:

$$f_2 = \boxed{504\,\text{Hz or } 496\,\text{Hz}}$$

(*b*) If the beat frequency increases, then $f_2 = 504$ Hz; if it decreases, $f_2 = 496$ Hz.

43 ••• **[SSM]** A stationary police radar gun emits microwaves at 5.00 GHz. When the gun is aimed at a car, it superimposes the transmitted and reflected waves. Because the frequencies of these two waves differ, beats are generated, with the speed of the car proportional to the beat frequency. The speed of the car, 83 mi/h, appears on the display of the radar gun. Assuming the car is moving along the line-of-sight of the police officer, and using the Doppler shift equations, (*a*) show that, for a fixed radar gun frequency, the beat frequency is proportional to the speed of the car. *HINT: Car speeds are tiny compared to the speed of light.* (*b*) What is the beat frequency in this case? (*c*) What is the calibration factor for this radar gun? That is, what is the beat frequency generated per mi/h of speed?

Picture the Problem The microwaves strike the speeding car at frequency f_r .This frequency will be less than f_s if the car is moving away from the radar gun and greater than f_s if the car is moving toward the radar gun. The frequency shift is given by Equation 15-42 (the low-speed, relative to light, approximation). The car then acts as a moving source emitting waves of frequency f_r. The radar gun detects waves of frequency f_r' that are either greater than or less than f_r depending on the direction the car is moving. The total frequency shift is the sum of the two frequency shifts.

(*a*) Express the frequency difference Δf as the sum of the frequency difference $\Delta f_1 = f_\text{r} - f_\text{s}$ and the frequency difference $\Delta f_2 = f_\text{r}' - f_\text{r}$:

$$\Delta f = \Delta f_1 + \Delta f_2 \qquad (1)$$

Using Equation 15-42, substitute for the frequency differences in equation (1):

$$\Delta f = -\frac{u}{c} f_\text{s} - \frac{u}{c} f_\text{r} = -\frac{u}{c}\left(f_\text{s} + f_\text{r}\right) \quad (2)$$

where $u = u_\text{s} \pm u_\text{r} = u_\text{r}$ is the speed of the source relative to the receiver.

Apply Equation 15-42 to Δf_1 to obtain:

$$\frac{\Delta f_1}{f_\text{s}} = \frac{f_\text{r} - f_\text{s}}{f_\text{s}} = -\frac{u_\text{r}}{c}$$

where we've used the minus sign because we know the frequency difference is a downshift.

Solving for f_r yields:

$$f_\text{r} = \left(1 - \frac{u_\text{r}}{c}\right) f_\text{s}$$

Substitute for f_r in equation (2) and simplify to obtain:

$$\begin{aligned}\Delta f &= -\frac{u_\text{r}}{c}\left(f_\text{s} + \left(1 - \frac{u_\text{r}}{c}\right) f_\text{s}\right)\\ &= -\frac{u_\text{r}}{c}\left(2 - \frac{u_\text{r}}{c}\right) f_\text{s}\\ &= -2\left(\frac{u_\text{r}}{c}\right) f_\text{s} + \left(\frac{u_\text{r}}{c}\right)^2 f_\text{s}\end{aligned}$$

Because $\frac{u_\text{r}}{c} << 1$:

$$\Delta f \approx -2 f_\text{s}\frac{u_\text{r}}{c} \Rightarrow \Delta f \propto \boxed{u_\text{r}}$$

(*b*) Substitute numerical values and evaluate $|\Delta f|$:

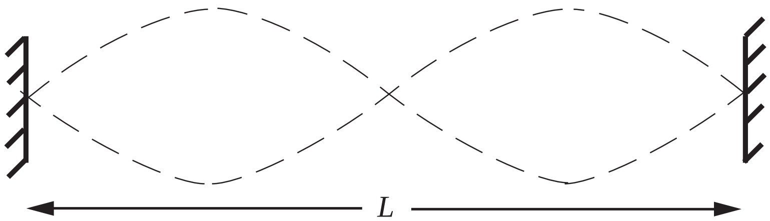
$$|\Delta f| \approx 2\left(5.00\times10^{9}\ \text{Hz}\right)\frac{\left(83\,\text{mi/h}\times\dfrac{0.4470\ \text{m/s}}{1\,\text{mi/h}}\right)}{2.998\times10^{8}\ \text{m/s}} = \boxed{1.2\ \text{kHz}}$$

(*c*) The calibration factor is $\frac{1.24\ \text{kHz}}{83\ \text{mi/h}} = \boxed{15\ \text{Hz/mi/h}}$.

Standing Waves

44 • A string fixed at both ends is 3.00 m long. It resonates in its second harmonic at a frequency of 60.0 Hz. What is the speed of transverse waves on the string?

Picture the Problem The pictorial representation shows the fixed string vibrating in its second harmonic. We can use $v = f\lambda$ to relate the second-harmonic frequency to the wavelength of the standing wave for the second harmonic.



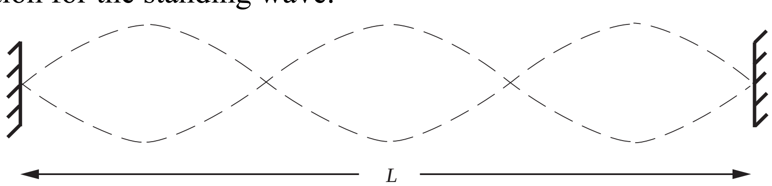
Relate the speed of transverse waves on the string to their frequency and wavelength: $v = f_2\lambda_2$

Express λ_2 in terms of the length L of the string: $\lambda_2 = L$

Substitute for λ_2 and evaluate v: $v = f_2L = (60.0\,\text{s}^{-1})(3.00\,\text{m}) = \boxed{180\,\text{m/s}}$

45 • A string 3.00 m long and fixed at both ends is vibrating in its third harmonic. The maximum displacement of any point on the string is 4.00 mm. The speed of transverse waves on this string is 50.0 m/s. (*a*) What are the wavelength and frequency of this standing wave? (*b*) Write the wave function for this standing wave.

Picture the Problem The pictorial representation shows the string fixed at both ends vibrating in its third harmonic. (*a*) We can find the wavelength of this standing wave from the standing-wave condition for a string fixed at both ends and its frequency from $v = f_3\lambda_3$. (*b*) We can use the wave function for a standing wave on a string fixed at both ends ($y_n(x,t) = A_n \sin k_n x \cos \omega_n t$) to write the wave function for the standing wave.



(*a*) Using the standing-wave condition for a string fixed at both ends, relate the length of the string to the wavelength of the harmonic mode in which it is vibrating:

$$L = n\frac{\lambda_n}{2},\ n = 1, 2, 3, \ldots \Rightarrow \lambda_3 = \frac{2}{3}L$$

Substitute the numerical value of L and evaluate λ_3:

$$\lambda_3 = \frac{2}{3}(3.00\,\text{m}) = \boxed{2.00\,\text{m}}$$

Express the frequency of the third harmonic in terms of the speed of transverse waves on the string and their wavelength:

$$f_3 = \frac{v}{\lambda_3} = \frac{50.0\,\text{m/s}}{2.00\,\text{m}} = \boxed{25.0\,\text{Hz}}$$

(*b*) Write the equation for a standing wave, fixed at both ends, in its third harmonic:

$$y_3(x,t) = A_3 \sin k_3 x \cos \omega_3 t$$

Evaluate k_3:

$$k_3 = \frac{2\pi}{\lambda_3} = \frac{2\pi}{2.00\,\text{m}} = \pi\,\text{m}^{-1}$$

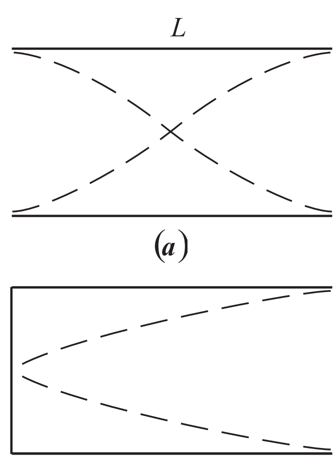
Evaluate ω_3:

$$\omega_3 = 2\pi f_3 = 2\pi\left(25.0\,\text{s}^{-1}\right) = 50.0\pi\,\text{s}^{-1}$$

Substitute to obtain: $\boxed{y_3(x,t) = (4.00\,\text{mm})\sin\left(\pi\,\text{m}^{-1}\right)x\cos\left(50.0\pi\,\text{s}^{-1}\right)t}$

46 • Calculate the fundamental frequency for an organ pipe, with an effective length equal to 10 m, that is (*a*) open at both ends and (*b*) stopped at one end.

Picture the Problem The first harmonic displacement-wave pattern in an organ pipe open at both ends and vibrating in its fundamental mode is represented in Part (*a*) of the diagram. Part (*b*) of the diagram shows the wave pattern corresponding to the fundamental frequency for a pipe of the same length L that is stopped at one end. We can relate the wavelength to the frequency of the fundamental modes using $v = f\lambda$.



(*a*)

(*b*)

(*a*) Express the dependence of the frequency of the fundamental mode of vibration in the open pipe on its wavelength:

$$f_{1,\text{open}}=\frac{v}{\lambda_{1,\text{open}}}$$

Relate the length of the open pipe to the wavelength of the fundamental mode:

$$\lambda_{1,\text{open}}=2L$$

Substitute and evaluate $f_{1,\text{open}}$:

$$f_{1,\text{open}}=\frac{v}{2L}=\frac{343\,\text{m/s}}{2(10\,\text{m})}=\boxed{17\,\text{Hz}}$$

(*b*) Express the dependence of the frequency of the fundamental mode of vibration in the closed pipe on its wavelength:

$$f_{1,\text{closed}}=\frac{v}{\lambda_{1,\text{closed}}}$$

Relate the length of the closed pipe to the wavelength of the fundamental mode:

$$\lambda_{1,\text{closed}}=4L$$

Substitute for $\lambda_{1,\text{closed}}$ to obtain:

$$f_{1,\text{closed}}=\frac{v}{4L}$$

Substitute numerical values and evaluate $f_{1,\text{closed}}$:

$$f_{1,\text{closed}}=\frac{343\,\text{m/s}}{4(10\,\text{m})}=\boxed{8.6\,\text{Hz}}$$

47 • [SSM] A 5.00-g, 1.40-m long flexible wire has a tension of 968 N and is fixed at both ends. (*a*) Find the speed of transverse waves on the wire. (*b*) Find the wavelength and frequency of the fundamental. (*c*) Find the frequencies of the second and third harmonics.

Picture the Problem We can find the speed of transverse waves on the wire using $v=\sqrt{F_\text{T}/\mu}$ and the wavelengths of any harmonic from $L=n\frac{\lambda_n}{2}$, where n = 1, 2, 3, … We can use $v=f\lambda$ to find the frequency of the fundamental. For a wire fixed at both ends, the higher harmonics are integer multiples of the first harmonic (fundamental).

(*a*) Relate the speed of transverse waves on the wire to the tension in the wire and its linear density:

$$v=\sqrt{\frac{F_T}{\mu}}=\sqrt{\frac{F_T L}{m}}$$

Substitute numerical values and evaluate *v*:

$$v=\sqrt{\frac{968\,\text{N}}{(0.00500\,\text{kg})/(1.40\,\text{m})}}=\boxed{521\,\text{m/s}}$$

(*b*) Using the standing-wave condition for a wire fixed at both ends, relate the length of the wire to the wavelength of the harmonic mode in which it is vibrating:

$$L=n\frac{\lambda_n}{2},\ n=1,2,3,\ldots$$

Solve for λ_1:

$$\lambda_1=2L=2(1.40\,\text{m})=\boxed{2.80\,\text{m}}$$

Express the frequency of the first harmonic in terms of the speed and wavelength of the waves:

$$f_1=\frac{v}{\lambda_1}=\frac{521\,\text{m/s}}{2.80\,\text{m}}=\boxed{186\,\text{Hz}}$$

(*c*) Because, for a wire fixed at both ends, the higher harmonics are integer multiples of the first harmonic:

$$f_2=2\,f_1=2(186\,\text{Hz})=\boxed{372\,\text{Hz}}$$

and

$$f_3=3\,f_1=3(186\,\text{Hz})=\boxed{558\,\text{Hz}}$$

48 • A taut, 4.00-m-long rope has one end fixed and the other end free. (The free end is attached to a long, light string.) The speed of waves on the rope is 20.0 m/s. (*a*) Find the frequency of the fundamental. (*b*) Find the second harmonic. (*c*) Find the third harmonic.

Picture the Problem We can use Equation 16-13, $f_n=n\frac{v}{4L}=nf_1, n=1,3,5,\ldots,$ to find the resonance frequencies for a rope that is fixed at one end.

(*a*) Using the resonance-frequency condition for a rope fixed at one end, relate the resonance frequencies to the speed of the waves and the length of the rope:

$$f_n=n\frac{v}{4L}=nf_1, n=1,3,5,\ldots$$

Solving for f_1 yields:

$$f_1=\frac{20.0\,\text{m/s}}{4(4.00\,\text{m})}=\boxed{1.25\,\text{Hz}}$$

(*b*) Because this rope is fixed at just one end, it does not support a second harmonic.

(*c*) For the third harmonic, $n = 3$: $$f_3 = 3f_1 = 3(1.25\,\text{Hz}) = \boxed{3.75\,\text{Hz}}$$

49 • A steel piano wire without windings has a fundamental frequency of 200 Hz. When it is wound with copper wire, its linear mass density is doubled. What is its new fundamental frequency, assuming that the tension is unchanged?

Picture the Problem We can find the fundamental frequency of the piano wire using the general expression for the resonance frequencies of a wire fixed at both ends, $f_n = n\dfrac{v}{2L} = nf_1,\ n = 1, 2, 3, \ldots$, with $n = 1$. We can use $v = \sqrt{F_\text{T}/\mu}$ to express the frequencies of the fundamentals of the two wires in terms of their linear densities.

Relate the fundamental frequency of the piano wire to the speed of transverse waves on it and its linear density:

$$f_1 = \frac{v}{2L}$$

Express the dependence of the speed of transverse waves on the tension and linear density:

$$v = \sqrt{\frac{F_\text{T}}{\mu}}$$

Substituting for v yields:

$$f_1 = \frac{1}{2L}\sqrt{\frac{F_\text{T}}{\mu}}$$

Doubling the linear density results in a new fundamental frequency f' given by:

$$f_1' = \frac{1}{2L}\sqrt{\frac{F_\text{T}}{2\mu}} = \frac{1}{\sqrt{2}}\left(\frac{1}{2L}\sqrt{\frac{F_\text{T}}{\mu}}\right) = \frac{1}{\sqrt{2}}f_1$$

Substitute the numerical value of f_1 to obtain:

$$f_1' = \frac{1}{\sqrt{2}}(200\,\text{Hz}) = \boxed{141\,\text{Hz}}$$

50 • What is the greatest length that an organ pipe can have in order that its fundamental note be in the audible range (20 to 20,000 Hz) if (*a*) the pipe is stopped at one end and (*b*) it is open at both ends?

Picture the Problem Because the frequency and wavelength of sound waves are inversely proportional, the greatest length of the organ pipe corresponds to the lowest frequency in the normal hearing range. We can relate wavelengths to the length of the pipes using the expressions for the resonance frequencies for pipes that are open at both ends and stopped at one end.

Find the wavelength of a 20-Hz note:

$$\lambda_{\text{max}} = \frac{v}{f_{\text{lowest}}} = \frac{343\,\text{m/s}}{20\,\text{s}^{-1}} = 17.2\,\text{m}$$

(*a*) Relate the length L of a stopped-at-one-end organ pipe to the wavelengths of its standing waves:

$$L = n\frac{\lambda_n}{4},\ n = 1, 3, 5, ...$$

For $n = 1$:

$$L = \frac{\lambda_{\text{max}}}{4} = \frac{17.2\,\text{m}}{4} = \boxed{4.3\,\text{m}}$$

(*b*) Relate the length L of an open-at-both-ends organ pipe to the wavelengths of its standing waves:

$$L = n\frac{\lambda_n}{2},\ n = 1, 2, 3, ...$$

For $n = 2$:

$$L = \frac{\lambda_{\text{max}}}{2} = \frac{17.2\,\text{m}}{2} = \boxed{8.6\,\text{m}}$$

51 •• **[SSM]** The wave function $y(x,t)$ for a certain standing wave on a string fixed at both ends is given by $y(x,t) = 4.20\sin(0.200x)\cos(300t)$, where y and x are in centimeters and t is in seconds. (*a*) A standing wave can be considered as the superposition of two traveling waves. What are the wavelength and frequency of the two traveling waves that make up the specified standing wave? (*b*) What is the speed of these waves on this string? (*c*) If the string is vibrating in its fourth harmonic, how long is it?

Picture the Problem We can find λ and f by comparing the given wave function to the general wave function for a string fixed at both ends. The speed of the waves can then be found from $v = f\lambda$. We can find the length of the string from its fourth harmonic wavelength.

(*a*) Using the wave function, relate k and λ:

$$k = \frac{2\pi}{\lambda} \Rightarrow \lambda = \frac{2\pi}{k}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{2\pi}{0.200\,\text{cm}^{-1}} = 10\pi\,\text{cm} = \boxed{31.4\,\text{cm}}$$

Using the wave function, relate f and ω:

$$\omega = 2\pi f \Rightarrow f = \frac{\omega}{2\pi}$$

Substitute numerical values and evaluate f:

$$f = \frac{300\,\mathrm{s}^{-1}}{2\pi} = \boxed{47.7\,\mathrm{Hz}}$$

(b) The speed of the traveling waves is the ratio of their angular frequency and wave number:

$$v = \frac{\omega}{k} = \frac{300\,\mathrm{s}^{-1}}{0.200\,\mathrm{cm}^{-1}} = \boxed{15.0\,\mathrm{m/s}}$$

(c) Relate the length of the string to the wavelengths of its standing-wave patterns:

$$L = n\frac{\lambda_n}{2},\ n = 1, 2, 3, \ldots$$

Solve for L when $n = 4$:

$$L = 2\lambda_4 = 2(31.4\,\mathrm{cm}) = \boxed{62.8\,\mathrm{cm}}$$

52 •• The wave function $y(x,t)$ for a certain standing wave on a string that is fixed at both ends is given by $y(x,t) = (0.0500\ \mathrm{m})\sin(2.50\ \mathrm{m}^{-1}\ x)\cos(500\ \mathrm{s}^{-1}\ t)$. A standing wave can be considered as the superposition of two traveling waves. (a) What are the speed and amplitude of the two traveling waves that result in the specified standing wave? (b) What is the distance between successive nodes on the string? (c) What is the shortest possible length of the string?

Picture the Problem (a) v, ω and k are related according to $\omega = kv$. ω and k can be found from the given wave function. (b) In a standing wave pattern, the nodes are separated by one-half wavelength. (c) Because there is a standing wave on the string, the shortest possible length is one-half the wavelength of the waves interfering to produce the standing wave.

(a) The speed of a traveling wave is the ratio of its angular frequency and wave number:

$$v = \frac{\omega}{k}$$

Substitute numerical values and evaluate v:

$$v = \frac{500\,\mathrm{s}^{-1}}{2.50\,\mathrm{m}^{-1}} = \boxed{200\,\mathrm{m/s}}$$

Express the amplitude of the standing wave A_{SW} in terms of the amplitude of the two traveling waves that result in the standing wave:

$$A_{\mathrm{SW}} = 2A \Rightarrow A = \tfrac{1}{2}A_{\mathrm{SW}}$$

Substitute for A_{SW} and evaluate A:

$$A = \tfrac{1}{2}(0.0500\,\text{m}) = \boxed{2.50\,\text{cm}}$$

(*b*) The distance between nodes is half the wavelength:

$$d = \tfrac{1}{2}\lambda = \tfrac{1}{2}\left(\frac{v}{f}\right) = \tfrac{1}{2}\left(\frac{2\pi v}{\omega}\right) = \frac{\pi v}{\omega}$$

Substitute numerical values and evaluate d:

$$d = \frac{\pi(200\,\text{m/s})}{500\,\text{s}^{-1}} = \boxed{1.26\,\text{m}}$$

(*c*) Because there is a standing wave on the string, the shortest possible length is:

$$L_{\text{min}} = \tfrac{1}{2}\lambda = \boxed{1.26\,\text{m}}$$

53 •• A 1.20-m-long pipe is stopped at one end. Near the open end, there is a loudspeaker that is driven by an audio oscillator whose frequency can be varied from 10.0 to 5000 Hz. (Neglect any end corrections.) (*a*) What is the lowest frequency of the oscillator that will produce resonance within the tube? (*b*) What is the highest frequency that will produce resonance? (*c*) How many different frequencies of the oscillator will produce resonance?

Picture the Problem (*a*) The lowest resonant frequency in this closed-at-one-end tube is its fundamental frequency. This frequency is related to its wavelength through $v = f_{\text{min}}\lambda_{\text{max}}$. (*b*) We can use the relationship between the nth harmonic and the fundamental frequency, $f_{\text{n}} = (2n+1)f_1, n = 1, 2, 3, \ldots$, to find the highest frequency less than or equal to 5000 Hz that will produce resonance.

(*a*) The wavelengths of the resonant frequencies in a stopped pipe of length L are given by:

$$\lambda_n = \frac{4L}{n}, n = 1, 3, 5, \ldots$$

λ_{max} corresponds to $n = 1$:

$$\lambda_{\text{max}} = 4L$$

Use $v = f_{\text{min}}\lambda_{\text{max}}$ to express f_{min}:

$$f_{\text{min}} = \frac{v}{\lambda_{\text{max}}} = \frac{v}{4L}$$

Substitute numerical values and evaluate f_{min}:

$$f_{\text{min}} = \frac{343\,\text{m/s}}{4(1.20\,\text{m})} = 71.46\,\text{Hz}$$
$$= \boxed{71.5\,\text{Hz}}$$

(*b*) Express the nth harmonic in terms of the fundamental frequency (first harmonic):

$$f_{\text{n}} = nf_1, n = 1, 3, 5, \ldots$$

To find the highest harmonic below 5000 Hz, let f_n = 5000 Hz:

$$5000\,\text{Hz} = n_{\text{highest}}(71.46\,\text{Hz})$$

Solve for n (an odd integer) to obtain (because there are only odd harmonics for a pipe stopped at one end):

$$n = 69$$

Evaluate f_{69}:

$$f_{69} = 69 f_1 = 69(71.46\,\text{Hz}) = \boxed{4.93\text{ kHz}}$$

(c) There are 69 odd harmonics higher than the fundamental frequency, so the total number resonant frequencies is $\boxed{35}$.

54 •• A 460-Hz tuning fork causes resonance in the tube depicted in Figure 16-33 when the length L of the air column above the water is 18.3 and 55.8 cm. (a) Find the speed of sound in air. (b) What is the end correction to adjust for the fact that the antinode does not occur exactly at the end of the open tube?

Picture the Problem Sound waves of frequency 460 Hz are excited in the tube, whose length L can be adjusted. Resonance occurs when the effective length of the tube $L_{\text{eff}} = L + \Delta L$ equals $\frac{1}{4}\lambda$, $\frac{3}{4}\lambda$, $\frac{5}{4}\lambda$, and so on, where λ is the wavelength of the sound. Even though the pressure node is not exactly at the end of the tube, the wavelength can be found from the fact that the distance between water levels for successive resonances is half the wavelength. We can find the speed from $v = f\lambda$ and the end correction from the fact that, for the fundamental, $L_{\text{eff}} = \frac{1}{4}\lambda = L_1 + \Delta L$, where L_1 is the distance from the top of the tube to the location of the first resonance.

(a) Relate the speed of sound in air to its wavelength and the frequency of the tuning fork:

$$v = f\lambda$$

Using the fact that nodes are separated by one-half wavelength, find the wavelength of the sound waves:

$$\lambda = 2(55.8\,\text{cm} - 18.3\,\text{cm}) = 75.0\,\text{cm}$$

Substitute numerical values and evaluate v:

$$v = (460\,\text{s}^{-1})(0.750\,\text{m}) = \boxed{345\,\text{m/s}}$$

(*b*) Relate the end correction ΔL to the wavelength of the sound and effective length of the tube:

$$L_{\text{eff}} = \tfrac{1}{4}\lambda = L_1 + \Delta L \Rightarrow \Delta L = \tfrac{1}{4}\lambda - L_1$$

Substitute numerical values and evaluate ΔL:

$$\Delta L = \tfrac{1}{4}(75.0\,\text{cm}) - 18.3\,\text{cm} = \boxed{0.5\,\text{cm}}$$

55 •• [SSM] An organ pipe has a fundamental frequency of 440.0 Hz at 16.00ºC. What will be the fundamental frequency of the pipe if the temperature increases to 32.00ºC (assuming the length of the pipe remains constant)? Would it be better to construct organ pipes from a material that expands substantially as the temperature increases or, should the pipes be made of material that maintains the same length at all normal temperatures?

Picture the Problem We can use $v = f\lambda$ to express the fundamental frequency of the organ pipe in terms of the speed of sound and $v = \sqrt{\dfrac{\gamma RT}{M}}$ to relate the speed of sound and the fundamental frequency to the absolute temperature.

Express the fundamental frequency of the organ pipe in terms of the speed of sound:

$$f = \frac{v}{\lambda}$$

Relate the speed of sound to the temperature:

$$v = \sqrt{\frac{\gamma RT}{M}}$$

where γ and R are constants, M is the molar mass, and T is the absolute temperature.

Substitute for v to obtain:

$$f = \frac{1}{\lambda}\sqrt{\frac{\gamma RT}{M}}$$

Using primed quantities to represent the higher temperature, express the new frequency as a function of T:

$$f' = \frac{1}{\lambda'}\sqrt{\frac{\gamma RT'}{M}}$$

As we have seen, λ is proportional to the length of the pipe. For the first question, we assume the length of the pipe does not change, so $\lambda = \lambda'$. Then the ratio of f' to f is:

$$\frac{f'}{f} = \sqrt{\frac{T'}{T}} \Rightarrow f' = f\sqrt{\frac{T'}{T}}$$

Evaluate f' for $T' = 305$ K and $T = 289$ K:

$$f' = f_{305\,\mathrm{K}} = f_{289\,\mathrm{K}}\sqrt{\frac{305\,\mathrm{K}}{289\,\mathrm{K}}}$$

$$= (440.0\,\mathrm{Hz})\sqrt{\frac{305\,\mathrm{K}}{289\,\mathrm{K}}} = \boxed{452\,\mathrm{Hz}}$$

Ideally, the pipe should expand so that v/L, where L is the length of the pipe, is independent of temperature.

56 •• According to theory, the end correction for a pipe is approximately $\Delta L = 0.3186D$, where D is the pipe diameter. Find the actual length of a pipe open at both ends that will produce a middle C (256 Hz) as its fundamental mode for pipes of diameter $D = 1.00$ cm, 10.0 cm, and 30.0 cm.

Picture the Problem We can express the wavelength of the fundamental in a pipe open at both ends in terms of the effective length of the pipe using $\lambda = 2L_{\mathrm{eff}} = 2(L + \Delta L)$, where L is the actual length of the pipe and $\lambda = v/f$. Solving these equations simultaneously will lead us to an expression for L as a function of D.

Express the wavelength of the fundamental in a pipe open at both ends in terms of the pipe's effective length L_{eff}:

$$\lambda = 2L_{\mathrm{eff}} = 2(L + \Delta L)$$

where L is its actual length.

Solve for L to obtain:

$$L = \frac{\lambda}{2} - \Delta L = \frac{\lambda}{2} - 0.3186D$$

Express the wavelength of middle C in terms of its frequency f and the speed of sound v:

$$\lambda = \frac{v}{f}$$

Substitute for λ to obtain:

$$L = \frac{v}{2f} - 0.3186D$$

Substitute numerical values to express L as a function of D:

$$L = \frac{343\,\mathrm{m/s}}{2(256\,\mathrm{s}^{-1})} - 0.3186D$$

$$= 0.670\,\mathrm{m} - 0.3186D$$

Evaluate L for $D = 1.00$ cm:

$$L = 0.670\,\mathrm{m} - 0.3186(0.0100\,\mathrm{m})$$

$$= \boxed{66.7\,\mathrm{cm}}$$

Evaluate L for $D = 10.0$ cm:

$$L = 0.670\,\text{m} - 0.3186(0.100\,\text{m}) = \boxed{63.8\,\text{cm}}$$

Evaluate L for $D = 30.0$ cm:

$$L = 0.670\,\text{m} - 0.3186(0.300\,\text{m}) = \boxed{57.4\,\text{cm}}$$

57 •• Assume a 40.0-cm-long violin string has a mass of 1.20 g and is vibrating in its fundamental mode at a frequency of 500 Hz. (*a*) What is the wavelength of the standing wave on the string? (*b*) What is the tension in the string? (*c*) Where should you place your finger to increase the fundamental frequency to 650 Hz?

Picture the Problem (*a*) We know that, when a string is vibrating in its fundamental mode, its ends are one-half wavelength apart. (*b*) We can use $v = f\lambda$ to express the fundamental frequency of the violin string in terms of the speed of waves in the string and $v = \sqrt{F_\text{T}/\mu}$ to relate the speed of waves in the string and the fundamental frequency to the tension in the string. (*c*) We can use this relationship between f and L, the length of the string, to find the length of string when it vibrates with a frequency of 650 Hz.

(*a*) Express the wavelength of the standing wave, vibrating in its fundamental mode, to the length L of the string:

$$\lambda = 2L = 2(40.0\,\text{cm}) = \boxed{80.0\,\text{cm}}$$

(*b*) Relate the speed of the waves combining to form the standing wave to its frequency and wavelength:

$$v = f\lambda$$

Express the speed of transverse waves as a function of the tension in the string:

$$v = \sqrt{\frac{F_\text{T}}{\mu}} = \sqrt{\frac{F_\text{T}L}{m}}$$

where m is the mass of the string and L is its length.

Substitute for v to obtain:

$$\sqrt{\frac{F_\text{T}L}{m}} = f\lambda \Rightarrow F_\text{T} = f^2\lambda^2\frac{m}{L}$$

Substitute numerical values and evaluate F:

$$F = \left(500\,\text{s}^{-1}\right)^2 (0.800\,\text{m})^2 \left(\frac{1.20\times10^{-3}\,\text{kg}}{0.400\,\text{m}}\right) = \boxed{480\,\text{N}}$$

(c) Using $v = f\lambda$ and assuming that the string is still vibrating in its fundamental mode, express its frequency in terms of its length:

$$f = \frac{v}{\lambda} = \frac{v}{2L} \Rightarrow L = \frac{v}{2f}$$

Letting primed quantities refer to a second length and frequency, express L' in terms of f':

$$L' = \frac{v}{2f'}$$

Express the ratio of L' to L and solve for L':

$$\frac{L'}{L} = \frac{f}{f'} \Rightarrow L' = \frac{f}{f'}L$$

Evaluate $L_{650\,\text{Hz}}$:

$$L_{650\,\text{Hz}} = \frac{500\,\text{Hz}}{650\,\text{Hz}} L_{500\,\text{Hz}} = \frac{500\,\text{Hz}}{650\,\text{Hz}}(40.0\,\text{cm}) = 30.77\,\text{cm}$$

You should place your finger 9.2 cm from the fixed end of the string.

58 •• The G string on a violin is 30.0 cm long. When played without fingering, it vibrates in its fundamental mode at a frequency of 196 Hz. The next higher notes on its C-major scale are A (220 Hz), B (247 Hz), C (262 Hz), and D (294 Hz). How far from the end of the string must a finger be placed to play each of these notes?

Picture the Problem Let f' represent the frequencies corresponding to the A, B, C, and D notes and $x(f')$ represent the distances from the end of the string that a finger must be placed to play each of these notes. Then, the distances at which the finger must be placed are given by $x(f') = L(f_G) - L(f')$.

Express the distances at which the finger must be placed in terms of the lengths of the G string and the frequencies f' of the A, B, C, and D notes:

$$x(f') = L(f_G) - L(f') \qquad (1)$$

Assuming that it vibrates in its fundamental mode, express the frequency of the G string in terms of its length:

$$f_G = \frac{v}{\lambda_G} = \frac{v}{2L_G} \Rightarrow L_G = \frac{v}{2f_G}$$

Letting primed quantities refer to the string lengths and frequencies of the A, B, C, and D notes, express L' in terms of f':

$$L' = \frac{v}{2f'}$$

Express the ratio of L' to L and solve for L':

$$\frac{L'}{L_G} = \frac{f_G}{f'} \Rightarrow L' = \frac{f_G}{f'} L_G$$

Evaluate $L' = L(f')$ for the notes A, B, C and D to complete the table:

Note	Frequency (Hz)	$L(f')$ (cm)
A	220	26.73
B	247	23.81
C	262	22.44
D	294	20.00

Use equation (1) to evaluate $x(f')$ and complete the table to the right:

Note	Frequency (Hz)	$L(f')$ (cm)	$x(f')$ (cm)
A	220	26.73	$\boxed{3.3}$
B	247	23.81	$\boxed{6.2}$
C	262	22.44	$\boxed{7.6}$
D	294	20.00	$\boxed{10}$

59 •• A string that has a linear mass density of 4.00×10^{-3} kg/m is under a tension of 360 N and is fixed at both ends. One of its resonance frequencies is 375 Hz. The next higher resonance frequency is 450 Hz. (*a*) What is the fundamental frequency of this string? (*b*) Which harmonics have the given frequencies? (*c*) What is the length of the string?

Picture the Problem We can use the fact that the resonance frequencies are multiples of the fundamental frequency to find both the fundamental frequency and the harmonic numbers corresponding to 375 Hz and 450 Hz. We can find the length of the string by relating it to the wavelength of the waves on it and the wavelength to the speed and frequency of the waves. The speed of the waves is, in turn, a function of the tension in the string and its linear density, both of which we are given.

(*a*) Express 375 Hz as an integer multiple of the fundamental frequency of the string:

$$nf_1 = 375\,\text{Hz} \qquad (1)$$

Express 450 Hz as an integer multiple of the fundamental frequency of the string:

$$(n+1)f_1 = 450\,\text{Hz} \qquad (2)$$

Solve equations (1) and (2) simultaneously for f_1:

$$f_1 = \boxed{75\,\text{Hz}}$$

(*b*) Substitute in equation (1) to obtain:

$n = 5 \Rightarrow$ the harmonics are the $\boxed{5^{\text{th}}}$ and $\boxed{6^{\text{th}}}$.

(*c*) Express the length of the string as a function of the speed of transverse waves on it and its fundamental frequency:

$$L = \frac{\lambda}{2} = \frac{v}{2f_1}$$

Express the speed of transverse waves on the string in terms of the tension in the string and its linear density:

$$v = \sqrt{\frac{F_\text{T}}{\mu}}$$

Substitute for v to obtain:

$$L = \frac{1}{2f_1}\sqrt{\frac{F_\text{T}}{\mu}}$$

Substitute numerical values and evaluate L:

$$L = \frac{1}{2(75\,\text{s}^{-1})}\sqrt{\frac{360\,\text{N}}{4.00\times10^{-3}\,\text{kg/m}}} = \boxed{2.0\,\text{m}}$$

60 •• A string fixed at both ends has successive resonances with wavelengths of 0.54 m for the *n*th harmonic and 0.48 m for the (*n* + 1)th harmonic. (*a*) Which harmonics are these? (*b*) What is the length of the string?

Picture the Problem (*a*) We can use the fact that the resonance frequencies are multiples of the fundamental frequency and are expressible in terms of the speed of the waves and their wavelengths to find the harmonic numbers corresponding to wavelengths of 0.54 m and 0.48 m. (*b*) We can find the length of the string by using the standing-wave condition for a string fixed at both ends.

(*a*) Express the frequency of the *n*th harmonic in terms of its wavelength:

$$nf_1 = \frac{v}{\lambda_n} = \frac{v}{0.54\,\text{m}}$$

Express the frequency of the (*n* + 1)th harmonic in terms of its wavelength:

$$(n+1)f_1 = \frac{v}{\lambda_{n+1}} = \frac{v}{0.48\,\text{m}}$$

Solve these equations simultaneously for *n*:

$n = 8 \Rightarrow$ the harmonics are the $\boxed{8^{\text{th}}}$ and $\boxed{9^{\text{th}}}$.

(*b*) Using the standing-wave condition, both ends fixed, relate the length of the string to the wavelength of its *n*th harmonic:

$$L = n\frac{\lambda_n}{2},\ n = 1, 2, 3, \ldots$$

Evaluate *L* for the eighth harmonic:

$$L = 8\left(\frac{0.54\,\text{m}}{2}\right) = \boxed{2.2\,\text{m}}$$

61 •• **[SSM]** The strings of a violin are tuned to the tones G, D, A, and E, which are separated by a fifth from one another. That is, $f(\text{D}) = 1.5f(\text{G})$, $f(\text{A}) = 1.5f(\text{D}) = 440$ Hz, and $f(\text{E}) = 1.5f(\text{A})$. The distance between the bridge at the scroll and the bridge over the body, the two fixed points on each string, is 30.0 cm. The tension on the E string is 90.0 N. (*a*) What is the linear mass density of the E string? (*b*) To prevent distortion of the instrument over time, it is important that the tension on all strings be the same. Find the linear mass densities of the other strings.

Picture the Problem (*a*) The mass densities of the strings are related to the transverse wave speed and tension through $v = \sqrt{F_\text{T}/\mu}$. (*b*) We can use $v = f\lambda = 2fL$ to relate the frequencies of the violin strings to their lengths and linear densities.

(*a*) Relate the speed of transverse waves on a string to the tension in the string and solve for the string's linear density:

$$v = \sqrt{\frac{F_\text{T}}{\mu}} \Rightarrow \mu = \frac{F_\text{T}}{v^2}$$

Express the dependence of the speed of the transverse waves on their frequency and wavelength:

$$v = f_\text{E}\lambda = 2f_\text{E}L$$

Substituting for v gives:

$$\mu_E = \frac{F_{T,E}}{4f_E^2L^2}$$

Substitute numerical values and evaluate μ_E:

$$\mu_E = \frac{90.0\,\text{N}}{4\left[1.5\left(440\,\text{s}^{-1}\right)\right]^2\left(0.300\,\text{m}\right)^2} = 5.74\times10^{-4}\,\text{kg/m} = \boxed{0.574\,\text{g/m}}$$

(*b*) Evaluate μ_A:

$$\mu_A = \frac{90.0\,\text{N}}{4\left(440\,\text{s}^{-1}\right)^2\left(0.300\,\text{m}\right)^2} = 1.29\times10^{-3}\,\text{kg/m} = \boxed{1.29\,\text{g/m}}$$

Evaluate μ_D:

$$\mu_D = \frac{90.0\,\text{N}}{4\left(293\,\text{s}^{-1}\right)^2\left(0.300\,\text{m}\right)^2} = 2.91\times10^{-3}\,\text{kg/m} = \boxed{2.91\,\text{g/m}}$$

Evaluate μ_G:

$$\mu_G = \frac{90.0\,\text{N}}{4\left(195\,\text{s}^{-1}\right)^2\left(0.300\,\text{m}\right)^2} = \boxed{6.57\,\text{g/m}}$$

62 •• On a cello, like most other stringed instruments, the positioning of the fingers by the player determines the fundamental frequencies of the strings. Suppose that one of the strings on a cello is tuned to play a middle C (262 Hz) when played at its full length. By what fraction must that string be shortened in order to play a note that is the interval of a third higher (namely, an E, (330 Hz)? How about a fifth higher or a G (392 Hz)?

Picture the Problem The speed of a wave on a string is the product of its wavelength and frequency. In this problem, the standing waves are at the fundamental frequency; that is, the only nodes are at the ends of the strings and the wavelength is twice the length of the string. The speed of a wave on a string is determined by the tension in the string and its mass density. Pressing the string against the neck of the cello does not change the tension in the string appreciably and so we can ignore this very small increase in tension in our solution of the problem. Because the length of the string is half the wavelength of the standing wave on it we compare the lengths of the string for the various notes by comparing the wavelengths corresponding to these frequencies.

The wavelength of a standing wave on a string is given by:

$$\lambda = \frac{v}{f} = \frac{1}{f}\sqrt{\frac{F_T}{\mu}}$$

Express the wavelength corresponding to middle C:

$$\lambda_C = \frac{1}{f_C}\sqrt{\frac{F_T}{\mu}} \quad (1)$$

Express he wavelength corresponding to an E:

$$\lambda_E = \frac{1}{f_E}\sqrt{\frac{F_T}{\mu}} \quad (2)$$

Express he wavelength corresponding to a G:

$$\lambda_G = \frac{1}{f_G}\sqrt{\frac{F_T}{\mu}} \quad (3)$$

Divide equation (2) by equation (1) and simplify to obtain:

$$\frac{\lambda_E}{\lambda_C} = \frac{\frac{1}{f_E}\sqrt{\frac{F_T}{\mu}}}{\frac{1}{f_C}\sqrt{\frac{F_T}{\mu}}} = \frac{f_C}{f_E}$$

Substitute numerical values to obtain:

$$\frac{\lambda_E}{\lambda_C} = \frac{262\text{ Hz}}{330\text{ Hz}} = 0.79 \approx \frac{4}{5}$$

Dividing equation (3) by equation (1) and simplifying yields:

$$\frac{\lambda_G}{\lambda_C} = \frac{f_C}{f_G}$$

Substitute numerical values to obtain:

$$\frac{\lambda_E}{\lambda_C} = \frac{262\text{ Hz}}{392\text{ Hz}} = 0.67 \approx \frac{2}{3}$$

Thus, to play and E, the string is shortened by one-fifth and, to play a G, the string is shortened by one-third.

63 •• To tune your violin, you first tune the A string to the correct pitch of 440 Hz and then you bow both it and an adjoining string simultaneously, all the while listening for beats. While bowing the A and E strings, you hear a beat frequency of 3.00 Hz and note that the beat frequency increases as the tension on the E string is increased. (The E string is to be tuned to 660 Hz.) (*a*) Why are beats produced by these two strings when bowed simultaneously? (*b*) What is the frequency of the E string vibration when the beat frequency is 3.00 Hz?

Picture the Problem (*a*) and (*b*) Beat frequencies are heard when the strings are vibrating with slightly different frequencies. To understand the beat frequency heard when the A and E strings are bowed simultaneously, we need to consider the harmonics of both strings. In Part (*c*) we'll relate the tension in the string to the frequency of its vibration and set up a proportion involving the frequencies corresponding to the two tensions that we can solve for the tension when the E string is perfectly tuned.

(*a*) The two sounds produce a beat because the third harmonic of the A string is the same as the second harmonic of the E string, and the original frequency of the E string is slightly greater than 660 Hz. If $f_E = (660 + \Delta f)\text{Hz}$, a beat of $2\Delta f$ will be heard.

(*b*) Because f_{beat} increases with increasing tension, the frequency of the E string is greater than 660 Hz. Thus the frequency of the E string is:

$$f_E = 660\,\text{Hz} + \tfrac{1}{2}(3.00\,\text{Hz}) = 661.5\,\text{Hz} = \boxed{662\,\text{Hz}}$$

64 •• A 2.00-m-long string fixed at one end and free at the other (the free end is fastened to the end of a long, light thread) is vibrating in its third harmonic with a maximum amplitude of 3.00 cm and a frequency 100 Hz. (*a*) Write the wave function for this vibration. (*b*) Write a function for the kinetic energy of a segment of the string of length *dx*, at a point a distance *x* from the fixed end, as a function of time *t*. At what times is this kinetic energy maximum? What is the shape of the string at these times? (*c*) Find the maximum kinetic energy of the string by integrating your expression for Part (*b*) over the total length of the string.

Picture the Problem ω_3 and k_3 can be expressed in terms of the given information and then substituted to find the wave function for the third harmonic. We can use the time-derivative of this expression (the transverse speed) to express the kinetic energy of a segment of mass *dm* and length *dx* of the string. Integrating this expression will give us the maximum kinetic energy of the string in terms of its mass.

(*a*) Write the general form of the wave function for the third harmonic:

$$y_3(x,t) = A_3 \sin k_3 x \cos \omega_3 t \qquad (1)$$

ω_3 is given by:

$$\omega_3 = 2\pi f_3$$

Using the standing-wave condition for a string fixed at one end, relate the length of the string to its third harmonic wavelength:

$$L = 3\frac{\lambda_3}{4} \Rightarrow \lambda_3 = \frac{4}{3}L$$

k_3 is given by:

$$k_3 = \frac{2\pi}{\lambda_3} = \frac{2\pi}{\frac{4}{3}L} = \frac{3\pi}{2L}$$

Substituting for ω_3 and k_3 in equation (1) yields:

$$y_3(x,t) = A_3 \sin\frac{3\pi}{2L}x \cos 2\pi f_3 t$$

Substitute numerical values to obtain:

$$y_3(x,t) = \boxed{(0.0300\,\text{m})\sin\left[\left(\frac{3\pi}{4}\,\text{m}^{-1}\right)x\right]\cos\left(200\pi\,\text{s}^{-1}\right)t}$$

where x is measured from the fixed end and $0 \le \boldsymbol{x} \le 2.00\,\text{m}$

(*b*) Express the kinetic energy of a segment of string of mass dm:

$$dK = \tfrac{1}{2}dmv_y^2$$

Express the mass of the segment in terms of its length dx and the linear density of the string:

$$dm = \mu dx$$

Using our result in (*a*), evaluate v_y:

$$\begin{aligned} v_y &= \frac{\partial}{\partial t}\left[(0.0300\,\text{m})\sin\left[\left(\frac{3\pi}{4}\,\text{m}^{-1}\right)x\right]\cos\left(200\pi\,\text{s}^{-1}\right)t\right] \\ &= -\left(200\pi\,\text{s}^{-1}\right)(0.03\,\text{m})\sin\left[\left(\frac{3\pi}{4}\,\text{m}^{-1}\right)x\right]\sin\left(200\pi\,\text{s}^{-1}\right)t \\ &= -(6\pi\,\text{m/s})\sin\left[\left(\frac{3\pi}{4}\,\text{m}^{-1}\right)x\right]\sin\left(200\pi\,\text{s}^{-1}\right)t \end{aligned}$$

Substitute in the expression for dK to obtain:

$$dK = \boxed{\tfrac{1}{2}\left[(6\pi\,\text{m/s})\sin\left[\left(\frac{3\pi}{4}\,\text{m}^{-1}\right)x\right]\sin\left(200\pi\,\text{s}^{-1}\right)t\right]^2 \mu dx}$$

Express the condition on the time that makes dK a maximum:

$$\sin\left(200\pi\,\text{s}^{-1}\right)t = 1$$

or

$$\left(200\pi\,\text{s}^{-1}\right)t = \frac{\pi}{2}, \frac{3\pi}{2}, \ldots$$

Solve for and evaluate t:

$$\begin{aligned} t &= \frac{1}{200\pi\,\text{s}^{-1}}\frac{\pi}{2}, \frac{1}{200\pi\,\text{s}^{-1}}\frac{3\pi}{2}, \ldots \\ &= \boxed{2.50\,\text{ms}, 7.50\,\text{ms}, \ldots} \end{aligned}$$

Because the string's maximum kinetic energy occurs when $y(x,t) = 0$. Thus the string is a straight line.

(*c*) Integrate dK from (*b*) over the length of the string to obtain:

$$K_{\max} = \int_0^L \tfrac{1}{2}\left[\omega A \sin kx \sin \omega t\right]^2 \mu dx$$
$$= \tfrac{1}{2}\mu\omega^2 A^2 \int_0^L \sin^2 kx dx$$
$$= \tfrac{1}{2}\mu\omega^2 A^2 \frac{1}{k}\left[\tfrac{1}{2}kx - \tfrac{1}{4}\sin 2kx\right]_0^L$$
$$= \tfrac{1}{4}m\omega^2 A^2$$

where m is the mass of the string.

Substitute numerical values and evaluate $K_{\max}$:

$$K_{\max} = \tfrac{1}{4}m\left(200\pi\,\mathrm{s}^{-1}\right)^2 (0.0300\,\mathrm{m})^2$$
$$= \boxed{(88.8\,\mathrm{J/kg})m}$$

65 •• [SSM] A commonly used physics experiment that examines resonances of transverse waves on a string is shown in Figure 16-34. A weight is attached to the end of a string draped over a pulley; the other end of the string is attached to a mechanical oscillator that moves up and down at a frequency f that remains fixed throughout the demonstration. The length L between the oscillator and the pulley is fixed, and the tension is equal to the gravitational force on the weight. For certain values of the tension, the string resonates. Assume the string does not stretch or shrink as the tension is varied. You are in charge of setting up this apparatus for a lecture demonstration. (*a*) Explain why only certain discrete values of the tension result in standing waves on the string. (*b*) Do you need to increase or decrease the tension to produce a standing wave with an additional antinode? Explain. (*c*) Prove your reasoning in Part (*b*) by showing that the values for the tension $F_{\mathrm{T}n}$ for the nth standing-wave mode are given by $F_{\mathrm{T}n} = 4L^2 f^2 \mu / n^2$, and thus that $F_{\mathrm{T}n}$ is inversely proportional to n^2. (*d*) For your particular setup to fit onto the lecture table, you chose $L = 1.00$ m, $f = 80.0$ Hz, and $\mu = 0.750$ g/m. Calculate how much tension is needed to produce each of the first three modes (standing waves) of the string.

Picture the Problem (*c*) and (*d*) We can equate the expression for the velocity of a wave on a string and the expression for the velocity of a wave in terms of its frequency and wavelength to obtain an expression for the weight that must be suspended from the end of the string in order to produce a given standing wave pattern. By using the condition on the wavelength that must be satisfied at resonance, we can express the weight on the end of the string in terms of μ, f, L, and an integer n and then evaluate this expression for $n = 1$, 2, and 3 for the first three standing wave patterns.

(*a*) Because the frequency is fixed, the wavelength depends only on the tension on the string. This is true because the only parameter that can affect the wave speed on the string is the tension on the string. The tension on the string is provided by the weight hanging from its end. Given that the length of the string is fixed, only

certain wavelengths can resonate on the string. Thus, because only certain wavelengths are allowed, only certain wave speeds will work. This, in turn, means that only certain tensions, and therefore weights, will work.

(*b*) Higher frequency modes on the same length of string results in shorter wavelengths. To accomplish this without changing frequency, you need to reduce the wave speed. This is accomplished by reducing the tension in the string. Because the tension is provided by the weight on the end of the string, you must reduce the weight.

(*c*) Express the velocity of a wave on the string in terms of the tension F_T in the string and its linear density μ:

$$v=\sqrt{\frac{F_T}{\mu}}=\sqrt{\frac{w}{\mu}}$$

where w is the weight of the object suspended from the end of the string.

Express the wave speed in terms of its wavelength λ and frequency f:

$$v=f\lambda$$

Equate these expressions for v to obtain:

$$f\lambda=\sqrt{\frac{w}{\mu}}\Rightarrow w=\mu f^2\lambda^2$$

Express the condition on λ that corresponds to resonance:

$$\lambda=\frac{2L}{n}, n=1, 2, 3, \ldots$$

Substitute to obtain:

$$w_n=\mu f^2\left(\frac{2L}{n}\right)^2, n=1, 2, 3, \ldots$$

or

$$w_n=\boxed{\frac{4\mu f^2L^2}{n^2}}, n=1, 2, 3, \ldots$$

(*d*) Substitute numerical values for L, f, and μ to obtain:

$$w_n=\frac{4(0.750\,\text{g/m})(80.0\,\text{s}^{-1})^2(1.00\,\text{m})^2}{n^2}=\frac{19.20\,\text{N}}{n^2}$$

Evaluate w_n for $n = 1$:

$$w_1=\frac{19.20\,\text{N}}{(1)^2}=\boxed{19.2\,\text{N}}$$

Evaluate w_n for $n = 2$:

$$w_2=\frac{19.20\,\text{N}}{(2)^2}=\boxed{4.80\,\text{N}}$$

Evaluate w_n for $n = 3$:

$$w_3 = \frac{19.20\ \text{N}}{(3)^2} = \boxed{2.13\,\text{N}}$$

*Harmonic Analysis

66 • A guitar string is given a light pluck at its midpoint. A microphone on your computer detects the sound and a program on the computer determines that most of the subsequent sound consists of a 100-Hz tone accompanied by a bit of sound with a 300-Hz tone. What are the two dominant standing-wave modes on the string?.

Picture the Problem Plucking a string that is fixed at both ends in the middle results in an antinode at the midpoint of the string. Thus the primary modes of vibration will be those that have an antinode at the midpoint of the string. These modes are the odd harmonics and are given by $f_n = n\left(\frac{v}{2L}\right) = nf_1$ where $n = 1, 3, 5,$ …

The odd harmonics of a string that is plucked in the middle are given by:

$$f_n = n\left(\frac{v}{2L}\right) = nf_1 \text{ where } n = 1, 3, 5, \ldots$$

From the information given in the problem statement $f_1 = 100\ \text{Hz}$. Hence the first dominant standing wave mode is:

$$n = \boxed{1}$$

Noting that 300 Hz = 3(100 Hz), it follows that the second dominant standing wave mode is:

$$n = \boxed{3}$$

*Wave Packets

67 • **[SSM]** A tuning fork with natural frequency f_0 begins vibrating at time $t = 0$ and is stopped after a time interval Δt. The waveform of the sound at some later time is shown (Figure 16-35) as a function of x. Let N be an estimate of the number of cycles in this waveform. (*a*) If Δx is the length in space of this wave packet, what is the range in wave numbers Δk of the packet? (*b*) Estimate the average value of the wavelength λ in terms of N and Δx. (*c*) Estimate the average wave number k in terms of N and Δx. (*d*) If Δt is the time it takes the wave packet to pass a point in space, what is the range in angular frequencies $\Delta\omega$ of the packet? (*e*) Express f_0 in terms of N and Δt. (*f*) The number N is uncertain

by about ±1 cycle. Use Figure 16-35 to explain why. (*g*) Show that the uncertainty in the wave number due to the uncertainty in *N* is $2\pi/\Delta x$.

Picture the Problem We can approximate the duration of the pulse from the product of the number of cycles in the interval and the period of each cycle and the wavelength from the number of complete wavelengths in Δx. We can use its definition to find the average wave number from the average wavelength.

(*a*) Relate the duration of the pulse to the number of cycles in the interval and the period of each cycle:

$$\Delta t \approx NT = \boxed{\frac{N}{f_0}}$$

(*b*) There are about *N* complete wavelengths in Δx; hence:

$$\lambda \approx \boxed{\frac{\Delta x}{N}}$$

(*c*) Use its definition to express the wave number *k*:

$$k = \frac{2\pi}{\lambda} = \boxed{\frac{2\pi N}{\Delta x}}$$

(*d*) *N* is uncertain because the waveform dies out gradually rather than stopping abruptly at some time; hence, where the pulse starts and stops is not well defined.

(*e*) Using our result in part (*c*), express the uncertainty in *k*:

$$\Delta k = \frac{2\pi \Delta N}{\Delta x} = \boxed{\frac{2\pi}{\Delta x}}$$

because $\Delta N = \pm 1$.

General Problems

68 •• A 35-m-long string has a linear mass density of 0.0085 kg/m and is under a tension of 18 N. Find the frequencies of the lowest four harmonics if (*a*) the string is fixed at both ends, and if (*b*) the string is fixed at one end and free at the other. (That is, if the free end is attached to a long string of negligible mass.)

Picture the Problem We can use $v = f_n \lambda_n$ to express the resonance frequencies of the string in terms of their wavelengths and $L = n\frac{\lambda_n}{2}, n = 1, 2, 3, \ldots$ to relate the length of the string to the resonance wavelengths for a string fixed at both ends. Our strategy for part (*b*) will be the same … except that we'll use the standing-wave condition $L = n\frac{\lambda_n}{4}, n = 1, 3, 5, \ldots$ for strings with one end free.

(*a*) Relate the frequencies of the harmonics to their wavelengths and the speed of transverse waves on the string:

$$f_n = \frac{v}{\lambda_n}$$

Express the standing-wave condition for a string with both ends fixed:

$$L = n\frac{\lambda_n}{2},\ n = 1, 2, 3, \ldots \Rightarrow \lambda_n = \frac{2L}{n}$$

Substitute for λ_n to obtain:

$$f_n = n\frac{v}{2L}$$

Express the speed of the transverse waves as a function of the tension in the string:

$$v = \sqrt{\frac{F_\mathrm{T}}{\mu}}$$

Substituting for v in the expression for f_n yields:

$$f_n = n\frac{1}{2L}\sqrt{\frac{F_\mathrm{T}}{\mu}}$$

Substitute numerical values and simplify to obtain:

$$f_n = n\frac{1}{2(35\,\mathrm{m})}\sqrt{\frac{18\,\mathrm{N}}{0.0085\,\mathrm{kg/m}}} = n(0.657\,\mathrm{Hz})$$

Use this equation to calculate the 1st four harmonics:

$$f_1 = \boxed{0.66\,\mathrm{Hz}}$$

$$f_2 = 2(0.657\,\mathrm{Hz}) = \boxed{1.3\,\mathrm{Hz}}$$

$$f_3 = 3(0.657\,\mathrm{Hz}) = \boxed{2.0\,\mathrm{Hz}}$$

and

$$f_4 = 4(0.657\,\mathrm{Hz}) = \boxed{2.6\,\mathrm{Hz}}$$

(*b*) Express the standing-wave condition for a string fixed at one end:

$$L = n\frac{\lambda_n}{4},\ n = 1, 3, 5, \ldots \Rightarrow \lambda_n = \frac{4L}{n}$$

The resonance frequencies equation becomes:

$$f_n = n\frac{1}{4L}\sqrt{\frac{F_\mathrm{T}}{\mu}} = n\frac{1}{4(35\,\mathrm{m})}\sqrt{\frac{18\,\mathrm{N}}{0.0085\,\mathrm{kg/m}}} = n(0.3287\,\mathrm{Hz})$$

Calculate the 1st four harmonics:

$$f_1 = \boxed{0.33\,\text{Hz}}$$

$$f_3 = 3(0.3287\,\text{Hz}) = \boxed{0.99\,\text{Hz}}$$

$$f_5 = 5(0.3287\,\text{Hz}) = \boxed{1.6\,\text{Hz}}$$

and

$$f_7 = 7(0.3287\,\text{Hz}) = \boxed{2.3\,\text{Hz}}$$

69 •• Working for a small gold mining company, you stumble across an abandoned mine shaft that, because of decaying wood shoring, looks too dangerous to explore in person. To measure its depth, you employ an audio oscillator of variable frequency. You determine that successive resonances are produced at frequencies of 63.58 and 89.25 Hz. Estimate the depth of the shaft.

Picture the Problem We'll model the shaft as a pipe of length L with one end open. We can relate the frequencies of the harmonics to their wavelengths and the speed of sound using $v = f_n\lambda_n$ and the depth of the mine shaft to the resonance wavelengths using the standing-wave condition for a pipe with one end open; $L = n\frac{\lambda_n}{4},\ n = 1, 3, 5, \ldots$.

Relate the frequencies of the harmonics to their wavelengths and the speed of sound:

$$f_n = \frac{v}{\lambda_n}$$

Express the standing-wave condition for a pipe with one end open:

$$L = n\frac{\lambda_n}{4},\ n = 1, 3, 5, \ldots \Rightarrow \lambda_n = \frac{4L}{n}$$

Substitute for λ_n to obtain:

$$f_n = n\frac{v}{4L}$$

For f_n = 63.58 Hz:

$$63.58\,\text{Hz} = n\frac{v}{4L}$$

For f_{n+2} = 89.25 Hz:

$$89.25\,\text{Hz} = (n+2)\frac{v}{4L}$$

Divide either of these equations by the other and solve for n to obtain:

$$n = 4.95 \approx 5$$

Substitute in the equation for $f_n = f_5$ = 63.58 Hz:

$$f_5 = \frac{5v}{4L}$$

Solve for and evaluate L:

$$L = \frac{5v}{4f_5} = \frac{5(343\,\text{m/s})}{4(63.58\,\text{s}^{-1})} = \boxed{6.74\,\text{m}}$$

70 •• A 5.00-m-long string that is fixed at one end and attached to a long string of negligible mass at the other end is vibrating in its fifth harmonic, which has a frequency of 400 Hz. The amplitude of the motion at each antinode is 3.00 cm. (*a*) What is the wavelength of this wave? (*b*) What is the wave number? (*c*) What is the angular frequency? (*d*) Write the wave function for this standing wave.

Picture the Problem We can use the standing-wave condition for a string with one end free to find the wavelength of the 5th harmonic and the definitions of the wave number and angular frequency to calculate these quantitities. We can then substitute in the wave function for a wave in the *n*th harmonic to find the wave function for this standing wave.

(*a*) Express the standing-wave condition for a string with one end free:

$$L = n\frac{\lambda_n}{4},\ n = 1, 3, 5, \ldots$$

Solve for and evaluate λ_5:

$$\lambda_5 = \frac{4L}{5} = \frac{4(5.00\,\text{m})}{5} = \boxed{4.00\,\text{m}}$$

(*b*) Use its definition to calculate the wave number:

$$k_5 = \frac{2\pi}{\lambda_5} = \frac{2\pi}{4.00\,\text{m}} = \boxed{\frac{\pi}{2}\,\text{m}^{-1}}$$

(*c*) Using its definition, calculate the angular frequency:

$$\omega_5 = 2\pi f_5 = 2\pi(400\,\text{s}^{-1}) = \boxed{800\pi\,\text{s}^{-1}}$$

(*d*) Write the wave function for a standing wave in the *n*th harmonic:

$$y_n(x,t) = A\sin k_n x \cos \omega_n t$$

Substitute for A, k_5, and ω_5 to obtain:

$$y_5(x,t) = A\sin(k_5 x)\cos(\omega_5 t) = \boxed{(0.0300\,\text{m})\sin\left[\left(\frac{\pi}{2}\,\text{m}^{-1}\right)x\right]\cos\left(800\pi\,\text{s}^{-1}\right)t}$$

71 •• **[SSM]** The wave function for a standing wave on a string is described by $y(x,t) = (0.020)\sin(4\pi x)\cos(60\pi t)$, where y and x are in meters and t is in seconds. Determine the maximum displacement and maximum speed of a point on the string at (*a*) $x = 0.10$ m, (*b*) $x = 0.25$ m, (*c*) $x = 0.30$ m, and (*d*) $x = 0.50$ m.

Picture the Problem The coefficient of the factor containing the time dependence in the wave function is the maximum displacement of any point on the string. The time derivative of the wave function is the instantaneous speed of any point on the string and the coefficient of the factor containing the time dependence is the maximum speed of any point on the string.

Differentiate the wave function with respect to t to find the speed of any point on the string:

$$\begin{aligned} v_y &= \frac{\partial}{\partial t}\left[(0.020)\sin 4\pi x \cos 60\pi t\right] \\ &= -(0.020)(60\pi)\sin 4\pi x \sin 60\pi t \\ &= -1.2\pi \sin 4\pi x \sin 60\pi t \end{aligned}$$

(a) Referring to the wave function, express the maximum displacement of the standing wave:

$$y_{\text{max}}(x) = (0.020\,\text{m})\sin\left[\left(4\pi\,\text{m}^{-1}\right)x\right] \quad (1)$$

Evaluate equation (1) at $x = 0.10$ m:

$$\begin{aligned} y_{\text{max}}(0.10\,\text{m}) &= (0.020\,\text{m}) \\ &\quad \times \sin\left[\left(4\pi\,\text{m}^{-1}\right)(0.10\,\text{m})\right] \\ &= \boxed{1.9\,\text{cm}} \end{aligned}$$

Referring to the derivative of the wave function with respect to t, express the maximum speed of the standing wave:

$$v_{y,\text{max}}(x) = (1.2\pi\,\text{m/s})\sin\left[\left(4\pi\,\text{m}^{-1}\right)x\right] \quad (2)$$

Evaluate equation (2) at $x = 0.10$ m:

$$\begin{aligned} v_{y,\text{max}}(0.10\,\text{m}) &= (1.2\pi\,\text{m/s}) \\ &\quad \times \sin\left[\left(4\pi\,\text{m}^{-1}\right)(0.10\,\text{m})\right] \\ &= \boxed{3.6\,\text{m/s}} \end{aligned}$$

(b) Evaluate equation (1) at $x = 0.25$ m:

$$\begin{aligned} y_{\text{max}}(0.25\,\text{m}) &= (0.020\,\text{m}) \\ &\quad \times \sin\left[\left(4\pi\,\text{m}^{-1}\right)(0.25\,\text{m})\right] \\ &= \boxed{0} \end{aligned}$$

Evaluate equation (2) at $x = 0.25$ m:

$$\begin{aligned} v_{y,\text{max}}(0.25\,\text{m}) &= (1.2\pi\,\text{m/s}) \\ &\quad \times \sin\left[\left(4\pi\,\text{m}^{-1}\right)(0.25\,\text{m})\right] \\ &= \boxed{0} \end{aligned}$$

(*c*) Evaluate equation (1) at $x = 0.30$ m:

$$y_{\max}(0.30\,\text{m}) = (0.020\,\text{m}) \times \sin\left[\left(4\pi\,\text{m}^{-1}\right)(0.30\,\text{m})\right] = \boxed{-1.2\,\text{cm}}$$

Evaluate equation (2) at $x = 0.30$ m:

$$v_{y,\max}(0.30\,\text{m}) = \left|(1.2\pi\,\text{m/s}) \times \sin\left[\left(4\pi\,\text{m}^{-1}\right)(0.30\,\text{m})\right]\right| = \boxed{2.2\,\text{m/s}}$$

(*d*) Evaluate equation (1) at $x = 0.50$ m:

$$y_{\max}(0.50\,\text{m}) = (0.020\,\text{m}) \times \sin\left[\left(4\pi\,\text{m}^{-1}\right)(0.50\,\text{m})\right] = \boxed{0}$$

Evaluate equation (2) at $x = 0.50$ m:

$$v_{y,\max}(0.50\,\text{m}) = (1.2\pi\,\text{m/s}) \times \sin\left[\left(4\pi\,\text{m}^{-1}\right)(0.50\,\text{m})\right] = \boxed{0}$$

72 •• A 2.5-m-long string that has a mass of 0.10 kg is fixed at both ends and is under tension of 30 N. When the *n*th harmonic is excited, there is a node 0.50 m from one end. (*a*) What is *n*? (*b*) What are the frequencies of the first three harmonics of this string?

Picture the Problem In Part (*a*) we can use the standing-wave condition for a wire fixed at both ends and the fact that nodes are separated by one-half wavelength to find the harmonic number. In Part (*b*) we can relate the resonance frequencies to their wavelengths and the speed of transverse waves and express the speed of the transverse waves in terms of the tension in the wire and its linear density.

(*a*) Express the standing-wave condition for a wire fixed at both ends:

$$L = n\frac{\lambda_n}{2},\; n = 1, 2, 3, \ldots \qquad (1)$$

Solve for and evaluate λ_1:

$$\lambda_1 = 2L = 2(2.5\,\text{m}) = 5.0\,\text{m}$$

Relate the distance between nodes to the distance of the node closest to one end and solve for λ_n:

$$\tfrac{1}{2}\lambda_n = 0.50\,\text{m} \Rightarrow \lambda_n = 1.0\,\text{m}$$

Solving equation (1) for n yields:

$$n = \frac{2L}{\lambda_n}$$

Substitute for λ_n and L and evaluate n:

$$n = \frac{2(2.5\,\text{m})}{1.0\,\text{m}} = \boxed{5}$$

(*b*) Express the resonance frequencies in terms of the their wavelengths and the speed of transverse waves on the wire:

$$f_n = \frac{v}{\lambda_n} = n\frac{v}{\lambda_1}$$

Relate the speed of transverse waves on the wire to the tension in the wire:

$$v = \sqrt{\frac{F_\text{T}}{\mu}}$$

Substitute for v and simplify to obtain:

$$\begin{aligned} f_n &= n\frac{1}{\lambda_1}\sqrt{\frac{F_\text{T}L}{m}} \\ &= n\frac{1}{5.0\,\text{m}}\sqrt{\frac{(30\,\text{N})(2.5\,\text{m})}{0.10\,\text{kg}}} \\ &= n(5.48\,\text{Hz}) \end{aligned}$$

Evaluate f_n for $n = 1$, 2, and 3:

$$f_1 = \boxed{5.5\,\text{Hz}}$$

$$f_2 = 2(5.48\,\text{Hz}) = \boxed{11\,\text{Hz}}$$

and

$$f_3 = 3(5.48\,\text{Hz}) = \boxed{16\,\text{Hz}}$$

73 •• An organ pipe is such that its fundamental frequency is 220 Hz. It is placed in an atmosphere of sulfur hexafluoride (SF_6) at the same temperature and pressure. The molar mass of air is 29.0×10^{-3} kg/mol and the molar mass of SF_6 is 146×10^{-3} kg/mol. What is the fundamental frequency of the organ pipe when it is in an atmosphere of SF_6?

Picture the Problem Because sulfur hexafluoride is a heavy gas, we should expect the fundamental frequency (which is a function of the speed of sound) to be lower in an atmosphere of SF_6 than it is in air under normal conditions. We can use the relationship between the speed of a sound wave and its wavelength and frequency, together with $v = \sqrt{\gamma RT/M}$, where M is the molar mass, to express the fundamental frequency of the organ pipe in SF_6 in terms of its fundamental frequency in air.

The fundamental frequency of the organ pipe in SF_6 is given by:

$$f_{1,\mathrm{SF_6}} = \frac{v_{\mathrm{SF_6}}}{\lambda_1} = \frac{\sqrt{\dfrac{\gamma RT}{M_{\mathrm{SF_6}}}}}{\lambda_1} = \sqrt{\frac{\gamma RT}{\lambda_1^2 M_{\mathrm{SF_6}}}}$$

The fundamental frequency of the organ pipe in air is given by:

$$f_{1,\mathrm{air}} = \frac{v_{\mathrm{air}}}{\lambda_1} = \frac{\sqrt{\dfrac{\gamma RT}{M_{\mathrm{air}}}}}{\lambda_1} = \sqrt{\frac{\gamma RT}{\lambda_1^2 M_{\mathrm{air}}}}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{f_{1,\mathrm{SF_6}}}{f_{1,\mathrm{air}}} = \frac{\sqrt{\dfrac{\gamma RT}{\lambda_1^2 M_{\mathrm{SF_6}}}}}{\sqrt{\dfrac{\gamma RT}{\lambda_1^2 M_{\mathrm{air}}}}} = \sqrt{\frac{M_{\mathrm{air}}}{M_{\mathrm{SF_6}}}}$$

Solving for $f_{1,\mathrm{SF_6}}$ yields:

$$f_{1,\mathrm{SF_6}} = \sqrt{\frac{M_{\mathrm{air}}}{M_{\mathrm{SF_6}}}}\, f_{1,\mathrm{air}}$$

Substitute numerical values and evaluate $f_{1,\mathrm{SF_6}}$:

$$f_{1,\mathrm{SF_6}} = \sqrt{\frac{29.0\times10^{-3}\ \mathrm{kg/mol}}{146\times10^{-3}\ \mathrm{kg/mol}}}\left(220\ \mathrm{Hz}\right) = \boxed{98.0\ \mathrm{Hz}}$$

74 •• During a lecture demonstration of standing waves, one end of a string is attached to a device that vibrates at 60 Hz and produces transverse waves of that frequency on the string. The other end of the string passes over a pulley, and the tension is varied by attaching weights to that end. The string has approximate nodes next to both the vibrating device and the pulley. (*a*) If the string has a linear mass density of 8.0 g/m and is 2.5 m long (from the vibrating device to the pulley), what must be the tension for the string to vibrate in its fundamental mode? (*b*) Find the tension necessary for the string to vibrate in its second, third, and fourth harmonic.

Picture the Problem We can use $v = \sqrt{F_{\mathrm{T}}/\mu}$ to express F as a function of v and $v = f\lambda$ to relate v to the frequency and wavelength of the string's fundamental mode. Because, for a string fixed at both ends, $f_n = nf_1$, we can extend our result in Part (*a*) to Part (*b*).

(*a*) Relate the speed of the transverse waves on the string to the tension in it:

$$v = \sqrt{\frac{F_{\mathrm{T}}}{\mu}} \Rightarrow F_{\mathrm{T}} = \mu v^2 \qquad (1)$$

Relate the speed of the transverse waves on the string to their frequency and wavelength:

$$v = f_1\lambda_1$$

Express the wavelength of the fundamental mode to the length of the string:

$$\lambda_1 = 2L$$

Substitute for λ_1 to obtain:

$$v = 2fL$$

Substitute for v in equation (1) to obtain:

$$F_T = 4f^2L^2\mu \qquad (2)$$

Substitute numerical values and evaluate F:

$$F_T = 4\left(60\,\text{s}^{-1}\right)^2(2.5\,\text{m})^2\left(8.0\times10^{-3}\,\text{kg/m}\right) = \boxed{0.72\,\text{kN}}$$

(*b*) For the *n*th harmonic, equation (2) becomes:

$$F_n = f_n^2L^2\mu = n^2f_1^2L^2\mu = n^2(720\,\text{N})$$

Evaluate this expression for $n = 2$, 3, and 4:

$$F_2 = 4(720\,\text{N}) = \boxed{2.9\,\text{kN}}$$

$$F_3 = 9(720\,\text{N}) = \boxed{6.5\,\text{kN}}$$

and

$$F_4 = 16(720\,\text{N}) = \boxed{12\,\text{kN}}$$

75 •• [SSM] Three successive resonance frequencies in an organ pipe are 1310, 1834, and 2358 Hz. (*a*) Is the pipe closed at one end or open at both ends? (*b*) What is the fundamental frequency? (*c*) What is the effective length of the pipe?

Picture the Problem (*a*) We can use the conditions $\Delta f = f_1$ and $f_n = nf_1$, where n is an integer, which must be satisfied if the pipe is open at both ends to decide whether the pipe is closed at one end or open at both ends. (*b*) Once we have decided this question, we can use the condition relating Δf and the fundamental frequency to determine the latter. In Part (*c*) we can use the standing-wave condition for the appropriate pipe to relate its length to its resonance wavelengths.

(*a*) Express the conditions on the frequencies for a pipe that is open at both ends:

$$\Delta f = f_1$$

and

$$f_n = nf_1$$

Evaluate $\Delta f = f_1$: $\Delta f = 1834\,\text{Hz} - 1310\,\text{Hz} = 524\,\text{Hz}$

Using the 2nd condition, find n:

$$n = \frac{f_n}{f_1} = \frac{1310\,\text{Hz}}{524\,\text{Hz}} = 2.5$$

$\boxed{\text{The pipe is closed at one end.}}$

(*b*) Express the condition on the frequencies for a pipe that is open at both ends:

$$\Delta f = 2f_1 \Rightarrow f_1 = \tfrac{1}{2}\Delta f$$

Substitute numerical values and evaluate f_1:

$$f_1 = \tfrac{1}{2}(524\,\text{Hz}) = \boxed{262\,\text{Hz}}$$

(*c*) Using the standing-wave condition for a pipe open at one end, relate the effective length of the pipe to its resonance wavelengths:

$$L = n\frac{\lambda_n}{4},\ n = 1, 3, 5, \ldots$$

For $n = 1$ we have:

$$\lambda_1 = \frac{v}{f_1} \text{ and } L = \frac{\lambda_1}{4} = \frac{v}{4f_1}$$

Substitute numerical values and evaluate L:

$$L = \frac{343\,\text{m/s}}{4\left(262\,\text{s}^{-1}\right)} = \boxed{32.7\,\text{cm}}$$

76 •• During an experiment studying the speed of sound in air using an audio oscillator and a tube open at one end and stopped at the other, a particular resonant frequency is found to have nodes roughly 6.94 cm apart. The oscillator's frequency is increased, and the next resonant frequency found has nodes 5.40 cm apart. (*a*) What are the two resonant frequencies? (*b*) What is the fundamental frequency? (*c*) Which harmonics are these two modes? The speed of sound is 343 m/s.

Picture the Problem (*a*) Because adjacent nodes are separated by one-half wavelength, we can find the frequencies from our knowledge of the speed of sound in air the wavelengths of the standing-wave patterns. (*b*) These frequencies are consecutive odd-multiples (the tube is half-open) of the fundamental frequency. (*c*) The frequencies found in Part (*a*) are integer multiples of the fundamental frequency.

(*a*) The frequencies are determined by the speed of sound in air and by the wavelengths of the standing-wave patterns:

$$f_n = \frac{v}{\lambda_n}$$

Because the nodes are a half-wavelength apart:

$$\lambda_n = 2d_{\text{node-to-node}}$$

Substitute for λ_n to obtain:

$$f_n = \frac{v}{2d_{\text{node-to-node}}}$$

Substitute numerical values and evaluate the two frequencies:

$$f_n = \frac{343\text{ m/s}}{2(6.94\text{ cm})} = 2471\text{ Hz} = \boxed{2.47\text{ kHz}}$$

and

$$f_{n'} = \frac{343\text{ m/s}}{2(5.40\text{ cm})} = 3176\text{ Hz} = \boxed{3.18\text{ kHz}}$$

(*b*) Assuming the two frequencies are adjacent resonant frequencies, they are odd multiples (because the tube is half-open) of the fundamental frequency:

$$nf_1 = 2471\text{ Hz}$$

and

$$(n+2)f_1 = 3176\text{ Hz}$$

Subtract the first of these equations from the second to obtain:

$$(n+2)f_1 - nf_1 = 3176\text{ Hz} - 2471\text{ Hz} = 705\text{ Hz}$$

Solving for f_1 yields:

$$f_1 = \tfrac{1}{2}(705\text{ Hz}) = \boxed{353\text{ Hz}}$$

(*c*) Divide f_n and $f_{n'}$ by f_1 to obtain:

$$n = \frac{2471\text{ Hz}}{f_1} = \frac{2471\text{ Hz}}{353\text{ Hz}} = \boxed{7}$$

and

$$n' = \frac{3176\text{ Hz}}{f_1} = \frac{3176\text{ Hz}}{353\text{ Hz}} = \boxed{9}$$

77 •• A standing wave on a rope is represented by the wave function $y(x,t) = (0.020\ ) \sin(\tfrac{1}{2}\pi x) \cos(40\pi t)$, where x and y are in meters and t is in seconds. (*a*) Write wave functions for two traveling waves that, when

superimposed, will produce this standing-wave pattern. (*b*) What is the distance between the nodes of the standing wave? (*c*) What is the maximum speed of the rope at $x = 1.0$ m? (*d*) What is the maximum acceleration of the rope at $x = 1.0$ m?

Picture the Problem We know that the superimposed traveling waves have the same wave number and angular frequency as the standing-wave function, have equal amplitudes that are half that of the standing-wave function, and travel in opposite directions. From inspection of the standing-wave function we note that $k = \frac{1}{2}\pi\,\text{m}^{-1}$ and $\omega = 40\pi\,\text{s}^{-1}$. We can express the speed of a segment of the rope by differentiating the standing-wave function with respect to time and the acceleration by differentiating the velocity function with respect to time.

(*a*) Write the wave function for the wave traveling in the +*x* direction:

$$y_1(x,t) = \boxed{(0.010\,\text{m})\sin\left[\left(\frac{\pi}{2}\text{m}^{-1}\right)x - \left(40\pi\,\text{s}^{-1}\right)t\right]}$$

Write the wave function for the wave traveling in the −*x* direction:

$$y_2(x,t) = \boxed{(0.010\,\text{m})\sin\left[\left(\frac{\pi}{2}\text{m}^{-1}\right)x + \left(40\pi\,\text{s}^{-1}\right)t\right]}$$

(*b*) Express the distance *d* between adjacent nodes in terms of the wavelength of the standing wave:

$$d = \tfrac{1}{2}\lambda$$

Use the wave number to find the wavelength:

$$k = \tfrac{1}{2}\pi\,\text{m}^{-1} = \frac{2\pi}{\lambda} \text{ and } \lambda = 4.00\,\text{m}$$

Substitute for λ and evaluate *d*:

$$d = \tfrac{1}{2}(4.00\,\text{m}) = \boxed{2.00\,\text{m}}$$

(*c*) Differentiate the given wave function with respect to *t* to express the speed of any segment of the rope:

$$\begin{aligned} v_y(x,t) &= \frac{\partial}{\partial t}\left[(0.020\,\text{m})\sin\left(\frac{\pi}{2}\text{m}^{-1}\right)x\cos\left(40\pi\,\text{s}^{-1}\right)t\right] \\ &= -(0.80\pi\,\text{m/s})\sin\left(\frac{\pi}{2}\text{m}^{-1}\right)x\sin\left(40\pi\,\text{s}^{-1}\right)t \end{aligned}$$

Evaluate $\left|v_y(1.0\,\text{m},t)\right|$:

$$\begin{aligned}\left|v_y(1.0\,\text{m},t)\right| &= \left|-(0.80\pi\,\text{m/s})\sin\left(\frac{\pi}{2}\,\text{m}^{-1}\right)(1\,\text{m})\sin\left(40\pi\,\text{s}^{-1}\right)t\right| \\ &= (0.80\pi\,\text{m/s})\sin\left(40\pi\,\text{s}^{-1}\right)t \\ &= (2.5\,\text{m/s})\sin\left(40\pi\,\text{s}^{-1}\right)t\end{aligned}$$

The maximum speed of the rope at $x = 1.0$ m occurs when $\sin\left(40\pi\,\text{s}^{-1}\right)t = 1$:

$$v_{\text{max}} = \boxed{2.5\,\text{m/s}}$$

(*d*) Differentiate $v_y(x,t)$ with respect to time to obtain $a_y(x,t)$:

$$\begin{aligned}a_y(x,t) &= \frac{\partial}{\partial t}\left[-(0.80\pi\,\text{m/s})\sin\left(\frac{\pi}{2}\,\text{m}^{-1}\right)x\sin\left(40\pi\,\text{s}^{-1}\right)t\right] \\ &= -\left(32\pi^2\,\text{m/s}^2\right)\sin\left(\frac{\pi}{2}\,\text{m}^{-1}\right)x\cos\left(40\pi\,\text{s}^{-1}\right)t\end{aligned}$$

Evaluate $a_y(1.0\,\text{m},t)$:

$$\begin{aligned}a_y(1.0\,\text{m},t) &= \pm\left(32\pi^2\,\text{m/s}^2\right)\sin\left(\frac{\pi}{2}\,\text{m}^{-1}\right)(1\,\text{m})\cos\left(40\pi\,\text{s}^{-1}\right)t \\ &= \pm\left(32\pi^2\,\text{m/s}^2\right)\cos\left(40\pi\,\text{s}^{-1}\right)t \\ &= \pm\left(0.32\,\text{km/s}^2\right)\cos\left(40\pi\,\text{s}^{-1}\right)t\end{aligned}$$

The maximum acceleration of the rope at $x = 1.0$ m occurs when $\cos\left(40\pi\,\text{s}^{-1}\right)t = 1$:

$$v_{\text{max}} = \boxed{\pm 0.32\,\text{km/s}^2}$$

78 •• Two traveling wave pulses on a string are represented by the wave functions $y_1(x,t) = \dfrac{0.020}{2.0 + (x - 2.0t)^2}$ and $y_2(x,t) = \dfrac{-0.020}{2.0 + (x + 2.0t)^2}$, where x is in meters and t is in seconds. (*a*) Using a **spreadsheet program** or **graphing calculator**, make a graph of each wave function separately as a function of x at $t = 0$ and again at $t = 1.0$ s and describe the behavior of each as time increases. For each graph make your plot for –5.0 m < x < +5.0 m. (*b*) Graph the resultant wave function at $t = -1.0$ s, at $t = 0.0$ s and at $t = 1.0$ s.

Picture the Problem We'll use a spreadsheet program to graph the wave functions and their sum as functions of x at $t = 0$ and at $t = 1.0$ s. In (*b*) we can add the wave functions algebraically to find the result wave function at $t = 0$ and at $t = 1.0$ s.

(*a*) and (*b*) Part of the spreadsheet program to calculate values for $y_1(x,t)$ and $y_2(x,t)$ in the interval $-5.0\text{ m} < x < +5.0\text{ m}$ for the given times follows. The constants and cell formulas used are shown in the table.

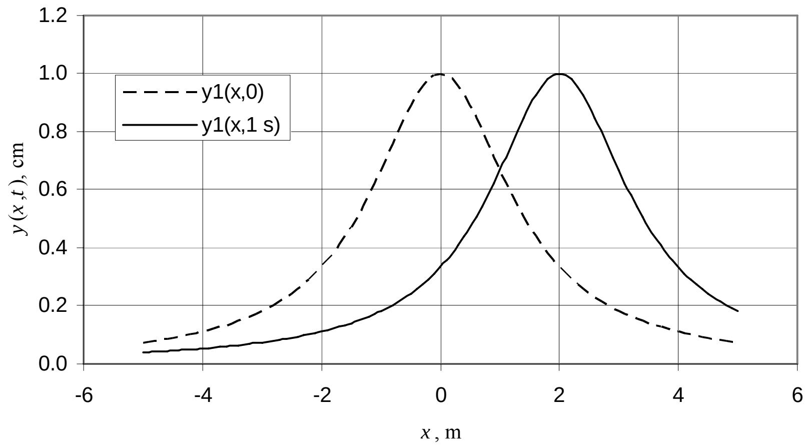
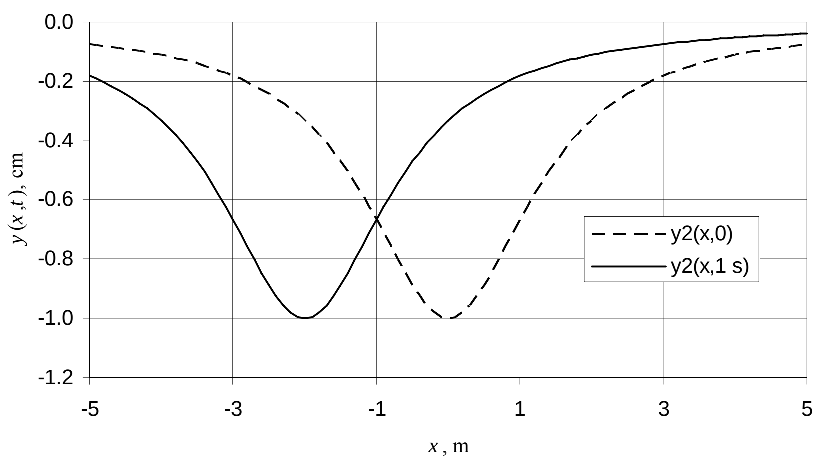
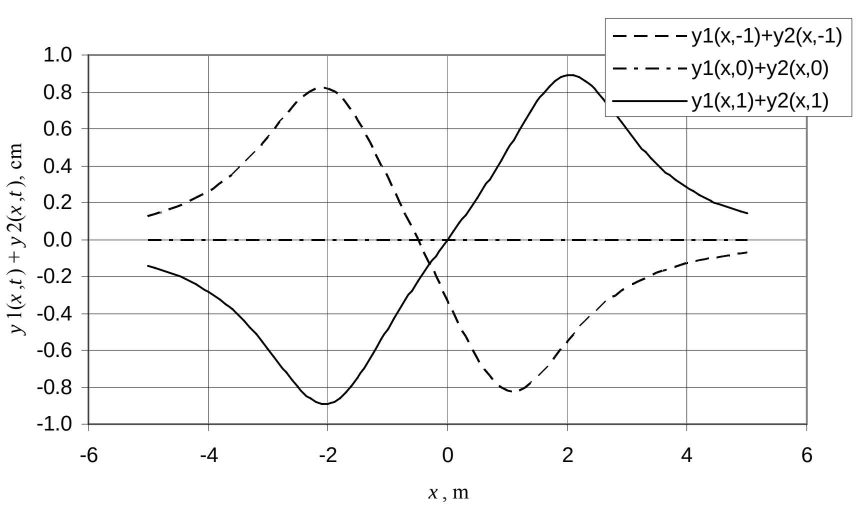
The following graph of $y_1(x,t)$ shows it traveling from left to right.



The following graph of $y_2(x,t)$ shows it traveling from right to left.



(*b*) The following graph shows the resultant wave function at $t = -1.0$ s, at $t = 0.0$ s and at $t = 1.0$ s.

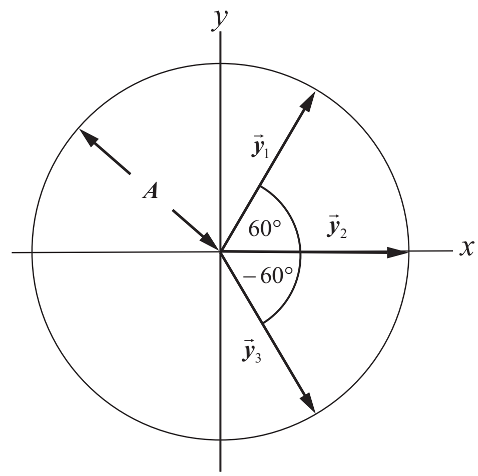


79 ••• Three waves that have the same frequency, wavelength, and amplitude are traveling along the x axis. The three waves are described by the following wave functions: $y_1(x,t) = (5.00\text{ cm})\sin\left(kx - \omega t - \frac{\pi}{3}\right)$,

$y_2(x,t) = (5.00\text{ cm})\sin(kx - \omega t)$, and $y_3(x,t) = (5.00\text{ cm})\sin\left(kx - \omega t + \frac{\pi}{3}\right)$,

where x is in meters and t is in seconds. The resultant wave function is given by $y(x,t) = A\sin(kx - \omega t + \delta)$. What are the values of A and δ?

Picture the Problem A harmonic function can be represented by a vector rotating at the angular frequency ω (see Chapter 14). The simplest way to do this problem is to use that representation. The vectors, of equal magnitude, are shown in the diagram. We can find the resultant wave function by finding the magnitude and direction of the resultant vector.



From the diagram it is evident that:

$$\sum y_y = 0$$

Find the sum of the x components of the vectors:

$$\sum y_x = (5.00\text{ cm})\cos 60° + (5.00\text{ cm})\cos 60° = 10.0\text{ cm}$$

Relate the magnitude of the resultant vector to the sum of its x and y components:

$$A = \sqrt{\left(\sum y_x\right)^2 + \left(\sum y_y\right)^2} = \sqrt{(10.0\text{ cm})^2 + (0)^2} = \boxed{10.0\text{ cm}}$$

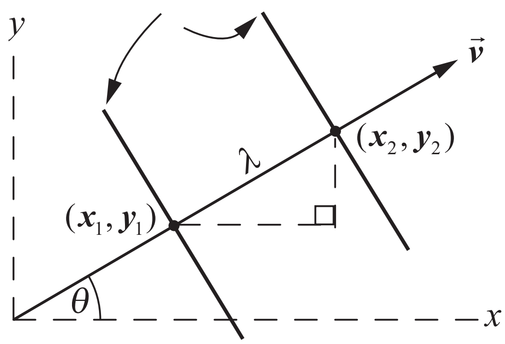
The direction of the resultant vector is δ:

$$\delta = \tan^{-1}\left(\frac{\sum y_y}{\sum y_x}\right) = \tan^{-1}\left(\frac{0}{10.0\text{ cm}}\right) = \boxed{0}$$

80 •• A harmonic pressure wave produced by a distant source is traveling through your vicinity, and the wave fronts that travel through your vicinity are vertical planes. Let the $+x$ direction be to the east and the $+y$ direction be toward the north. The wave function for the wave is $p(x, y, t) = A\cos(k_x x + k_y y - \omega t)$.

Show that the direction in which the wave is traveling makes an angle $\theta = \tan^{-1}(k_y/k_x)$ with the $+x$ direction and that the wave speed v is given by $v = \omega \Big/ \sqrt{k_x^2 + k_y^2}$.

Picture the Problem The diagram shows a snapshot of a two dimensional plane wave propagating at an angle θ with respect to the $+x$ axis. The view is along the $-z$ axis. The wave itself moves in a direction perpendicular to the wavefront. Choose two points (x_1, y_1) and (x_2, y_2) that have a separation of exactly 1 wavelength along the wave propagation direction. Let the snapshot be taken at some fixed time t.



Applying the Pythagorean theorem to the right triangle in the diagram yields:

$$\lambda = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} = \sqrt{(\Delta x)^2 + (\Delta y)^2} \quad (1)$$

Because k_x and k_y are the x and y components of $\vec{k}$:

$$k_x = k\cos\theta$$

and

$$k_y = k\sin\theta$$

Divide the second of these equations by the first to obtain:

$$\tan\theta = \frac{k_y}{k_x} \Rightarrow \theta = \boxed{\tan^{-1}\left(\frac{k_y}{k_x}\right)}$$

The wave speed v is the ratio of the angular frequency ω and wave number k:

$$v = \frac{\omega}{k} = \omega\frac{\lambda}{2\pi} \quad (2)$$

At time t, the phase at point 1 is $k_x x_1 + k_y y_1 - \omega t$ and the phase at point 2 is $k_x x_2 + k_y y_2 - \omega t$, so the phase difference is:

$$\delta = k_x x_2 + k_y y_2 - \omega t - (k_x x_1 + k_y y_1 - \omega t) = k_x \Delta x + k_y \Delta y$$

or, because the waves are separated by one wavelength, $\delta = 2\pi$ and we have $k_x \Delta x + k_y \Delta y = 2\pi$

Because $\tan\theta$ is also given by $\dfrac{\Delta y}{\Delta x}$:

$$\frac{\Delta y}{\Delta x} = \frac{k_y}{k_x} \Rightarrow \Delta y = \frac{k_y}{k_x}\Delta x$$

Substituting for Δy yields:

$$k_x \Delta x + k_y \frac{k_y}{k_x}\Delta x = 2\pi$$

Solve for Δx to obtain:

$$\Delta x = \frac{2\pi k_x}{k_x^2 + k_y^2}$$

Similarly:

$$\Delta y = \frac{2\pi k_y}{k_x^2 + k_y^2}$$

Substitute for Δx and Δy in equation (1) to obtain:

$$\lambda = \sqrt{\left(\frac{2\pi k_x}{k_x^2 + k_y^2}\right)^2 + \left(\frac{2\pi k_y}{k_x^2 + k_y^2}\right)^2} = \frac{2\pi}{\sqrt{k_x^2 + k_y^2}}$$

Substituting for λ in equation (2) yields:

$$v = \frac{\omega}{2\pi}\frac{2\pi}{\sqrt{k_x^2 + k_y^2}} = \boxed{\frac{\omega}{\sqrt{k_x^2 + k_y^2}}}$$

81 •• [SSM] The speed of sound in air is proportional to the square root of the absolute temperature T (Equation 15-5). (*a*) Show that if the air temperature changes by a small amount, the fractional change in the fundamental frequency of an organ pipe is approximately equal to half the fractional change in the absolute temperature. That is, show that $\Delta f/f \approx \frac{1}{2}\Delta T/T$, where f is the frequency at absolute temperature T and Δf is the change in frequency when the temperature changes by ΔT. (Ignore any change in the length of the pipe due to thermal expansion of the organ pipe.) (*b*) Suppose that an organ pipe that is stopped at one end has a fundamental frequency of 200.0 Hz when the temperature is 20.00ºC. Use the approximate result from Part (*a*) to determine its fundamental frequency when the temperature is 30.00ºC. (*c*) Compare your Part (*b*) result to what you would get

using exact calculations. (Ignore any change in the length of the pipe due to thermal expansion.)

Picture the Problem We can express the fundamental frequency of the organ pipe as a function of the air temperature and differentiate this expression with respect to the temperature to express the rate at which the frequency changes with respect to temperature. For changes in temperature that are small compared to the temperature, we can approximate the differential changes in frequency and temperature with finite changes to complete the derivation of $\Delta f/f = \frac{1}{2}\Delta T/T$. In Part (*b*) we'll use this relationship and the data for the frequency at 20.00°C to find the frequency of the fundamental at 30.00°C.

(*a*) Express the fundamental frequency of an organ pipe in terms of its wavelength and the speed of sound:

$$f = \frac{v}{\lambda}$$

Relate the speed of sound in air to the absolute temperature:

$$v = \sqrt{\frac{\gamma RT}{M}} = C\sqrt{T}$$

where

$$C = \sqrt{\frac{\gamma R}{M}} = \text{constant}$$

Defining a new constant C', substitute to obtain:

$$f = \frac{C}{\lambda}\sqrt{T} = C'\sqrt{T}$$

because λ is constant for the fundamental frequency we ignore any change in the length of the pipe.

Differentiate this expression with respect to T:

$$\frac{df}{dT} = \frac{1}{2}C'T^{-1/2} = \frac{f}{2T}$$

Separate the variables to obtain:

$$\frac{df}{f} = \frac{1}{2}\frac{dT}{T}$$

For $\Delta T << T$, we can approximate df by Δf and dT by ΔT to obtain:

$$\frac{\Delta f}{f} = \boxed{\frac{1}{2}\frac{\Delta T}{T}}$$

(*b*) Express the fundamental frequency at 30.00°C in terms of its frequency at 20.00°C:

$$f_{30} = f_{20} + \Delta f$$

Solve the result in (*a*) for Δf:

$$\Delta f = \tfrac{1}{2} f \frac{\Delta T}{T}$$

Substitute for Δf to obtain:

$$f_{30} = f_{20} + \tfrac{1}{2} f_{20} \frac{\Delta T}{T}$$

Substitute numerical values and evaluate f_{30}:

$$f_{30} = 200.0\,\text{Hz} + \tfrac{1}{2}(200.0\,\text{Hz})\frac{303.15\,\text{K} - 293.15\,\text{K}}{293.15\,\text{K}} = \boxed{203.4\,\text{Hz}}$$

(*c*) The exact expression for f_{30} is:

$$f_{30} = \frac{v_{30}}{\lambda} = \frac{\sqrt{\dfrac{\gamma R T_{30}}{M}}}{\lambda} = \sqrt{\frac{\gamma R T_{30}}{\lambda^2 M}}$$

The exact expression for f_{20} is:

$$f_{20} = \frac{v_{20}}{\lambda} = \frac{\sqrt{\dfrac{\gamma R T_{20}}{M}}}{\lambda} = \sqrt{\frac{\gamma R T_{20}}{\lambda^2 M}}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{f_{30}}{f_{20}} = \frac{\sqrt{\dfrac{\gamma R T_{30}}{\lambda^2 M}}}{\sqrt{\dfrac{\gamma R T_{20}}{\lambda^2 M}}} = \sqrt{\frac{T_{30}}{T_{20}}}$$

Solve for f_{30} to obtain:

$$f_{30} = \sqrt{\frac{T_{30}}{T_{20}}}\, f_{20}$$

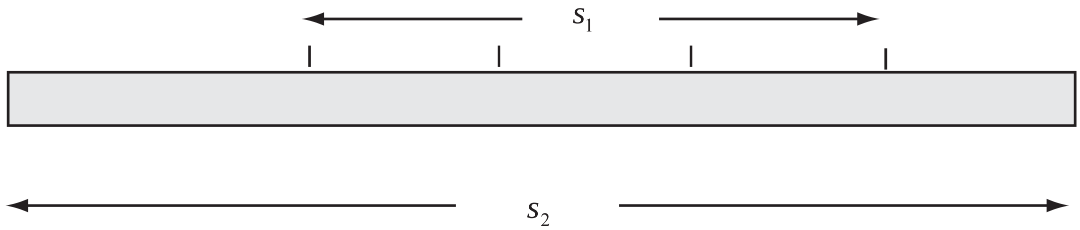
Substitute numerical values and evaluate f_{30}:

$$f_{30} = \sqrt{\frac{303.15\,\text{K}}{293.15\,\text{K}}}(200.0\,\text{Hz}) = \boxed{203.4\,\text{Hz}}$$

82 •• The pipe in Figure 16-36 is kept filled with natural gas (methane, CH_4). The pipe is punctured with a line of small holes 1.00 cm apart down its entire 2.20 m length. A speaker forms the closure on one end of the pipe, and a solid piece of metal closes the other end. What frequency is being played in this picture? The speed of sound in low pressure methane at room temperature is about 460 m/s.

Picture the Problem The frequency of the sound being played is given by $f = v/\lambda$. Because the holes are not visible in the photograph, we can not use their

separation to determine the wavelength of the sound being played. Instead, we can use the fact that the separation of the leftmost and rightmost flame maxima is 6 quarter wavelengths (drawing a standing wave pattern that is consistent with the flame pattern shown in Figure 16-36 will help you see this). Using any convenient scale to measure s_1 and s_2 (scaled distances on the photograph) and setting up a proportion involving these distances, the actual length L of the pipe, and the number of wavelengths in the distance s_1 will yield λ and, hence, f.



The frequency of the sound is given by:

$$f = \frac{v}{\lambda}$$

Letting L represent the length of the pipe yields:

$$\frac{\frac{6}{4}\lambda}{s_1} = \frac{L}{s_2} \Rightarrow \lambda = \frac{2Ls_1}{3s_2}$$

Substituting for λ yields:

$$f = \frac{v}{\frac{2Ls_1}{3s_2}} = \frac{3vs_2}{2Ls_1}$$

If s_1 = 10.5 cm and s_2 = 14.5 cm, then:

$$f = \frac{3(460\ \text{m/s})(14.5\ \text{cm})}{2(2.20\ \text{m})(10.5\ \text{cm})} = \boxed{433\ \text{Hz}}$$

83 •• Assume that your clarinet is entirely filled with helium and that before you start to play you fill your lungs with helium.. You pick up the clarinet and play it as though you were trying to play a B-flat, which has a frequency of 277 Hz. The frequency of 277 Hz is the natural resonance frequency of this clarinet with all finger holes closed and when filled with air. What frequency do you actually hear?

Picture the Problem The resonance frequency of the clarinet depends on the nature of the gas with which it is filled. We can express this frequency for both air and helium and express their ratio to eliminate the constant factors λ, R, and T. See Appendix C for the molar masses of helium and air.

Express the frequency of B-flat in helium:

$$f_{\text{B-flat, He}} = \frac{v_{\text{He}}}{\lambda} = \frac{1}{\lambda}\sqrt{\frac{\gamma_{\text{He}}RT}{M_{\text{He}}}}$$

Divide the second these equations by the first and simplify to obtain:

$$\frac{f_{\text{B-flat, He}}}{f_{\text{B-flat, air}}} = \frac{\frac{1}{\lambda}\sqrt{\frac{\gamma_{\text{He}}RT}{M_{\text{He}}}}}{\frac{1}{\lambda}\sqrt{\frac{\gamma_{\text{air}}RT}{M_{\text{air}}}}} = \sqrt{\frac{M_{\text{air}}\gamma_{\text{He}}}{M_{\text{He}}\gamma_{\text{air}}}}$$

Solving for $f_{\text{B-flat, He}}$ yields:

$$f_{\text{B-flat, He}} = \sqrt{\frac{M_{\text{air}}\gamma_{\text{He}}}{M_{\text{He}}\gamma_{\text{air}}}}\, f_{\text{B-flat, air}}$$

Substitute numerical values and evaluate $f_{\text{B-flat, He}}$:

$$f_{\text{B-flat, He}} = \sqrt{\frac{(28.81\text{ g/mol})(1.67)}{(4.003\text{ g/mol})(1.4)}}(277\text{ Hz}) = \boxed{812\text{ Hz}}$$

84 ••• A 2.00-m-long wire that is fixed at both ends is vibrating in its fundamental mode. The tension in the wire is 40.0 N and the mass of the wire is 0.100 kg. At the midpoint of the wire, the amplitude is 2.00 cm. (*a*) Find the maximum kinetic energy of the wire. (*b*) What is the kinetic energy of the wire at the instant the transverse displacement is given by $y = 0.0200\sin\left(\frac{\pi}{2}x\right)$, where y is in meters if x is in meters, for $0.00\text{ m} \le x \le 2.00\text{ m}$? (*c*) For what value of x is the average value of the kinetic energy per unit length the greatest? (*d*) For what value of x does the elastic potential energy per unit length have its maximum value?

Picture the Problem The maximum kinetic energy of the wire is given by $K_{\text{max}} = \frac{1}{4}m\omega^2A^2$. We can use $v = f\lambda$ and $v = \sqrt{F_{\text{T}}/\mu}$ to find an expression for ω. In Part (*d*) we'll use $\frac{\Delta U}{\Delta x} \approx \frac{1}{2}F_{\text{T}}\left(\frac{\partial y}{\partial x}\right)^2$ (Problem 15-104) to determine where the potential energy per unit length has its maximum value.

(*a*) The maximum kinetic energy of the wire is given by:

$$K_{\text{max}} = \frac{1}{4}m\omega^2A^2 \qquad (1)$$

Express ω_1 in terms of f_1:

$$\omega_1 = 2\pi f_1$$

Relate f_1 to the speed of transverse waves on the wire and the wavelength of the fundamental mode:

$$f_1 = \frac{v}{\lambda_1} = \frac{v}{2L}$$

where L is the length of the wire.

Express the speed of the transverse waves on the wire in terms of the tension in the wire:

$$v=\sqrt{\frac{F_{\mathrm{T}}}{\mu}}=\sqrt{\frac{F_{\mathrm{T}}L}{m}}$$

Substitute and simplify to obtain:

$$f_1=\frac{1}{2L}\sqrt{\frac{F_{\mathrm{T}}L}{m}}=\sqrt{\frac{F_{\mathrm{T}}}{4mL}}$$

Substitute for ω_1 and f_1 in equation (1) to obtain:

$$K_{\max}=\tfrac{1}{4}m\left[2\pi\sqrt{\frac{F_{\mathrm{T}}}{4mL}}\right]^2A^2=\frac{\pi^2F_{\mathrm{T}}}{4L}A^2$$

Substitute numerical values and evaluate $K_{\max}$:

$$K_{\max}=\frac{\pi^2(40.0\,\mathrm{N})}{4(2.00\,\mathrm{m})}\left(2.00\times10^{-2}\,\mathrm{m}\right)^2=\boxed{19.7\,\mathrm{mJ}}$$

(*b*) Express the wave function for a standing wave in its first harmonic:

$$y_1(x,t)=A_1\sin k_1x\cos\omega_1t \qquad (2)$$

At the instant the transverse displacement is given by (0.02 m) sin ($\pi x/2$):

$$\cos\omega_1t=1\Rightarrow\omega_1t=0$$

and

$$K=\boxed{0}$$

(*c*) *dK* is a maximum where the displacement of the wire is greatest; that is, at its midpoint:

$$x=\tfrac{1}{2}L=\tfrac{1}{2}(2.00\,\mathrm{m})=\boxed{1.00\,\mathrm{m}}$$

(*d*) From Problem 15-104:

$$\frac{\Delta U}{\Delta x}\approx\tfrac{1}{2}F_{\mathrm{T}}\left(\frac{\partial y}{\partial x}\right)^2$$

Express the condition on $\partial y/\partial x$ that maximizes $\Delta U/\Delta x$:

$$\frac{\partial y}{\partial x}=\left(\frac{\partial y}{\partial x}\right)_{\max}$$

Differentiate $y_1(x,t)=A_1\sin k_1x\cos\omega_1t$ with respect to x and set the derivative equal to zero for extrema:

$$\frac{\partial y_1}{\partial x}=\frac{\partial}{\partial x}\left(A_1\sin k_1x\cos\omega_1t\right)=k_1A_1\cos k_1x\cos\omega_1t=0$$

or

$$\cos k_1x=0$$

Solve for k_1x and then x:

$$k_1 x = \frac{\pi}{2} \Rightarrow x = \frac{\pi}{2k_1} = \frac{\pi\lambda}{2(2\pi)} = \tfrac{1}{4}\lambda$$

Because $\lambda = 2L$:

$$x = \tfrac{1}{2}L \Rightarrow x = \tfrac{1}{2}(2.00\,\text{m}) = \boxed{1.00\,\text{m}}$$

That is, the potential energy per unit length is a maximum at the midpoint of the wire.

Remarks: In Part (*d*) we've shown that Δ*U*/Δ*x* has an extreme value at *x* = 1 m. To show that Δ*U*/Δ*x* is a *maximum* at this location, you need to examine the sign of the 2nd derivative of $y_1(x,t)$ at this point.

85 ••• [SSM] In principle, a wave with almost any arbitrary shape can be expressed as a sum of harmonic waves of different frequencies. (*a*) Consider the function defined by

$$f(x) = \frac{4}{\pi}\left(\frac{\cos x}{1} - \frac{\cos 3x}{3} + \frac{\cos 5x}{5} - \ldots\right) = \frac{4}{\pi}\sum_{n=0}(-1)^n \frac{\cos[(2n+1)x]}{2n+1}$$

Write a **spreadsheet program** to calculate this series using a finite number of terms, and make three graphs of the function in the range $x = 0$ to $x = 4\pi$.. To create the first graph, for each value of x that you plot, approximate the sum from $n = 0$ to $n = \infty$ with the first term of the sum. To create the second and third graphs, use only the first five term and the first ten terms, respectively. This function is sometimes called the *square wave*. (*b*) What is the relation between this function and Liebnitz' series for π, $\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \ldots$?

A spreadsheet program to evaluate $f(x)$ is shown below. Typical cell formulas used are shown in the table.

Cell	Content/Formula	Algebraic Form

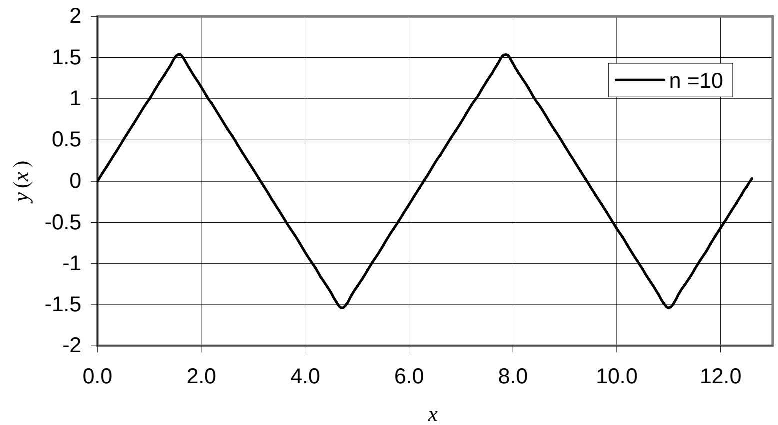
The following graph was obtain using $n = 10$.

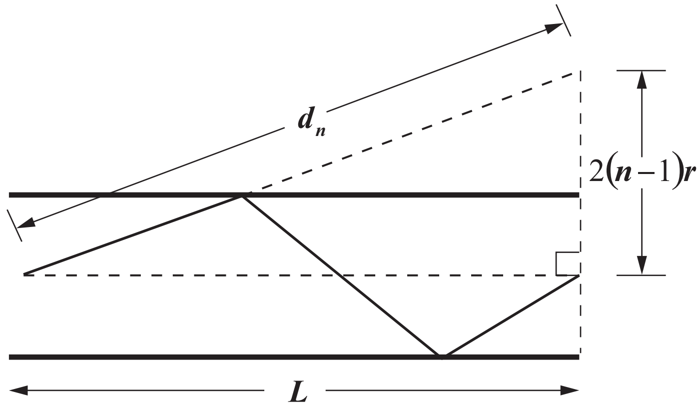


87 ••• If you clap your hands at the end of a long, cylindrical tube, the echo you hear back will not sound like the handclap; instead, you will hear what sounds like a whistle, initially at a very high frequency, but descending rapidly down to almost nothing. This "culvert whistler" is easily explained if you think of the sound from the clap as a single compression radiating outward from the hands. The echoes of the handclap arriving at your ear have traveled along different paths through the tube, as shown in Figure 16-37. The first echo to arrive travels straight down and straight back along the tube, while the second echo reflects once off of the center of the tube going out, and again going back, the third echo reflects twice at points 1/4 and 3/4 of the distance, etc. The tone of the sound you hear reflects the frequency at which these echoes reach your ears. (*a*) Show that the time delay between the n_{th} echo and the $n+1_{\text{th}}$ is

$$\Delta t_n = \frac{2}{v}\left(\sqrt{(2n)^2 r^2 + L^2} - \sqrt{\left[2(n-1)\right]^2 r^2 + L^2}\right)$$

where v is the speed of sound, L is the length of the tube and r is its radius.
(*b*) Using a **spreadsheet program** or **graphing calculator**, graph Δt_n versus n for $L = 90.0$ m, $r = 1.00$ m. (These values are the approximate length and radius of the long tube in the San Francisco Exploratorium.) Go to at least $n = 100$.
(*c*) From your graph, explain why the frequency decreases over time. What are the highest and lowest frequencies you will hear in the whistler?

Picture the Problem From the diagram above, the nth echo will reflect $n - 1$ times going out, and the same number of times going back. If we "unfold" the ray into a straight line, we get the representation shown below. Using this figure we can express the distance d_n traveled by the nth echo and then use this result to express the time delay between the n_{th} and $n + 1_{\text{th}}$ echoes. The reciprocal of this time delay is the frequency corresponding to the nth echo.



(*a*) Apply the Pythagorean theorem to the right triangle whose base is *L*, whose height is 2(*n* – 1), and whose hypotenuse is d_n to obtain:

$$d_n = 2\sqrt{4(n-1)^2 r^2 + L^2}$$

Express the time delay between the n_{th} and $n + 1_{\text{th}}$ echoes:

$$\Delta t_n = \frac{d_n}{v}$$

Substitute to obtain:

$$\Delta t_n = \frac{2}{v}\left(\sqrt{(2n)^2 r^2 + L^2} - \sqrt{[2(n-1)]^2 r^2 + L^2}\right)$$

(*b*) A spreadsheet program to calculate Δt_n as a function of *n* is shown below. The constants and cell formulas used are shown in the table.

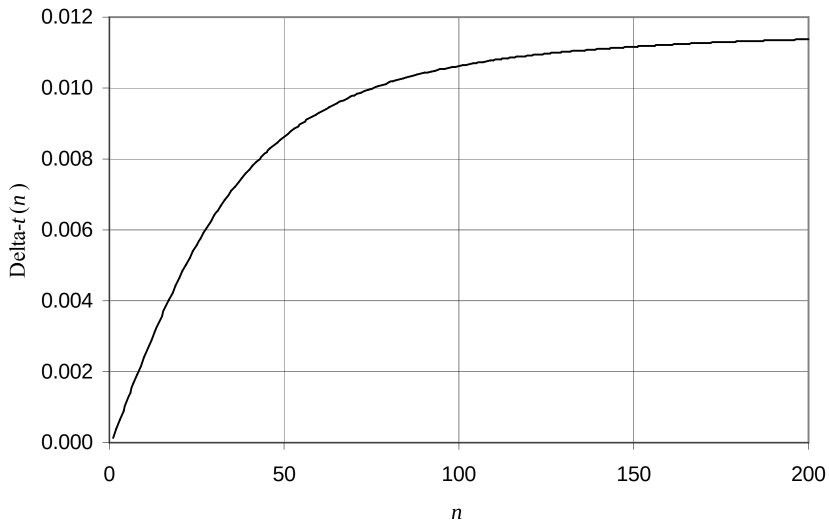
The graph of Δt_n as a function of n shown below was plotted using the data from columns B and D.



(c) The frequency heard at any time is $1/\Delta t_n$, so because Δt_n increases over time, the frequency of the culvert whistler decreases.

The highest frequency corresponds to $n = 1$ and is given by:

$$f_{\text{highest}} = \frac{1}{\Delta t_1}$$

Substitute for Δt_1 to obtain:

$$f_{\text{highest}} = \frac{1}{\Delta t_1} = \frac{v}{2\left(\sqrt{(2)^2 r^2 + L^2} - \sqrt{L^2}\right)}$$

Substitute numerical values and evaluate f_{highest}:

$$f_{\text{highest}} = \frac{343\,\text{m/s}}{2\left(\sqrt{4(1.00\,\text{m})^2 + (90.0\,\text{m})^2} - 90.0\,\text{m}\right)} = \boxed{7.72\,\text{kHz}}$$

The lowest frequency end can be found by examining the limit of Δt_n as $n \to \infty$:

$$\lim_{n\to\infty} \Delta t_n = \lim_{n\to\infty}\left[\frac{2}{v}\left((2n)\sqrt{r^2+\frac{L^2}{(2n)^2}}-2(n-1)\sqrt{r^2+\frac{L^2}{(2(n-1))^2}}\right)\right]$$
$$=\frac{2r}{v}(2n-2n+2)=\frac{4r}{v}$$

Express f_{lowest} in terms of Δt_∞:

$$f_{\text{lowest}}=\frac{1}{\Delta t_\infty}=\frac{v}{4r}$$

Substitute numerical values and evaluate f_{lowest}:

$$f_{\text{lowest}}=\frac{343\,\text{m/s}}{4(1.00\,\text{m})}=\boxed{85.8\,\text{Hz}}$$

Chapter 17
Temperature and the Kinetic Theory of Gases

Conceptual Problems

1 • True or false:

(*a*) The zeroth law of thermodynamics states that two objects in thermal equilibrium with each other must be in thermal equilibrium with a third object.
(*b*) The Fahrenheit and Celsius temperature scales differ only in the choice of the ice-point temperature.
(*c*) The Celsius degree and the kelvin are the same size.

(*a*) False. If two objects are in thermal equilibrium with a third, then they are in thermal equilibrium with each other.

(*b*) False. The Fahrenheit and Celsius temperature scales also differ in the number of intervals between the ice-point temperature and the steam-point temperature.

(*c*) True.

2 • How can you determine if two objects are in thermal equilibrium with each other when putting them into physical contact with each other would have undesirable effects? (For example, if you put a piece of sodium in contact with water there would be a violent chemical reaction.)

Determine the Concept Put each in thermal equilibrium with a third body; that is, a thermometer. If each body is in thermal equilibrium with the third, then they are in thermal equilibrium with each other.

3 • **[SSM]** ″Yesterday I woke up and it was 20ºF in my bedroom,″ said Mert to his old friend Mort. ″That's nothing,″ replied Mort. ″My room was –5.0ºC.″ Who had the colder room, Mert or Mort?

Picture the Problem We can decide which room was colder by converting 20°F to the equivalent Celsius temperature.

Using the Fahrenheit-Celsius conversion, convert 20°F to the equivalent Celsius temperature:

$$t_C = \tfrac{5}{9}(t_F - 32°F) = \tfrac{5}{9}(20°F - 32°F) = -6.7°C$$

so $\boxed{\text{Mert's room was colder.}}$

4 • Two identical vessels contain different ideal gases at the same pressure and temperature. It follows that (*a*) the number of gas molecules is the same in both vessels, (*b*) the total mass of gas is the same in both vessels, (*c*) the average speed of the gas molecules is the same in both vessels, (*d*) None of the above.

Determine the Concept Because the vessels are identical (have the same volume) and the two ideal gases are at the same pressure and temperature, the ideal-gas law ($PV = NkT$) tells us that the number of gas molecules must be the same in both vessels. $\boxed{(a)}$ is correct.

5 • **[SSM]** Figure 17-18 shows a plot of volume versus absolute temperature for a process that takes a fixed amount of an ideal gas from point A to point B. What happens to the pressure of the gas during this process?

Determine the Concept From the ideal-gas law, the equation of the line from the origin to the point (*T*,*V*) is $V = \frac{nR}{P}T$. The slope of this line is *nR*/*P*. During the process A $\rightarrow$ B the slope of the line from the origin to (*T*,*V*) continuously decreases, so the pressure continuously increases.

6 • Figure 17-19 shows a plot of pressure versus absolute temperature for a process that takes a sample of an ideal gas from point A to point B. What happens to the volume of the gas during this process?

Determine the Concept From the ideal-gas law, the equation of the line from the origin to the point (*T*,*P*) is $P = \frac{nR}{V}T$. The slope of this line is *nR*/*V*. During the process A $\rightarrow$ B the slope of the line from the origin to (*T*,*V*) continuously increases, so the volume continuously decreases.

7 • If a vessel contains equal amounts, by mass, of helium and argon, which of the following are true?

(*a*) The partial pressure exerted by each of the two gases on the walls of the container is the same.
(*b*) The average speed of a helium atom is the same as that of an argon atom.
(*c*) The number of helium atoms and argon atoms in the vessel are equal.
(*d*) None of the above.

Determine the Concept
(*a*) False. The gases occupy the same volume and they are at the same temperature. Because the masses of the gases are the same, the number of moles of each must be different. Because there are more moles of He, there are more

molecules of He. From the ideal-gas law, $P = nRT/V$, and so the partial pressure of He is greater.

(*b*) False. The average kinetic energy of both types of molecules is the same. Because He molecules have smaller masses, their average speed is larger.

(*c*) False. See (*a*).

(*d*) Because none of the above is true, $\boxed{(d)}$ is true.

8 • By what factor must the absolute temperature of a gas be increased to double the rms speed of its molecules?

Determine the Concept We can use $v_{\text{rms}} = \sqrt{3RT/M}$ to relate the temperature of a gas to the rms speed of its molecules.

Express the dependence of the rms speed of the molecules of a gas on their absolute temperature:

$$v_{\text{rms}} = \sqrt{\frac{3RT}{M}}$$

where R is the gas constant, M is the molar mass, and T is the absolute temperature.

Because $v_{\text{rms}} \propto \sqrt{T}$, the temperature must be ***quadrupled*** in order to double the rms speed of the molecules.

9 • Two different gases are at the same temperature. What can be said about the average translational kinetic energies of the molecules? What can be said about the rms speeds of the gas molecules?

Determine the Concept The average kinetic energies are equal. The ratio of their rms speeds is equal to the square root of the reciprocal of the ratio of their molecular masses.

10 • A vessel holds a mixture of helium (He) and methane (CH_4). The ratio of the rms speed of the He atoms to that of the CH_4 molecules is (*a*) 1, (*b*) 2, (*c*) 4, (*d*) 16

Picture the Problem We can express the rms speeds of the helium atoms and the methane molecules using $v_{\text{rms}} = \sqrt{3RT/M}$.

Express the rms speed of the helium atoms:

$$v_{\text{rms, He}} = \sqrt{\frac{3RT}{M_{\text{He}}}}$$

Express the rms speed of the methane molecules:

$$v_{\text{rms, CH}_4} = \sqrt{\frac{3RT}{M_{\text{CH}_4}}}$$

Divide the first of these equations by the second to obtain:

$$\frac{v_{\text{rms, He}}}{v_{\text{rms, CH}_4}} = \sqrt{\frac{M_{\text{CH}_4}}{M_{\text{He}}}}$$

Use Appendix C to find the molar masses of helium and methane:

$$\frac{v_{\text{rms, He}}}{v_{\text{rms, CH}_4}} = \sqrt{\frac{16\,\text{g/mol}}{4\,\text{g/mol}}} = 2$$

and $\boxed{(b)}$ is correct.

11 • True or false: If the pressure of a fixed amount of gas increases, the temperature of the gas must increase.

False. Whether the pressure changes also depends on whether and how the volume changes. In an isothermal process, the pressure can increase while the volume decreases and the temperature is constant.

12 • Why might the Celsius and Fahrenheit scales be more convenient than the absolute scale for ordinary, nonscientific purposes?

Determine the Concept For the Celsius scale, the ice point (0°C) and the boiling point of water at 1 atm (100°C) are more convenient than 273 K and 373 K; temperatures in roughly this range are normally encountered. On the Fahrenheit scale, the temperature of warm-blooded animals is roughly 100°F; this may be a more convenient reference than approximately 300 K. Throughout most of the world, the Celsius scale is the standard for nonscientific purposes.

13 • An astronomer claims that the temperature at the center of the Sun is about 10^7 degrees. Do you think that this temperature is in kelvins, degrees Celsius, or doesn't it matter?

Determine the Concept Because $T = t_C + 273.15$ K and $10^7 >> 273$, it doesn't matter.

14 • Imagine that you have a fixed amount of ideal gas in a container that expands to maintain constant pressure. If you double the absolute temperature of the gas, the average speed of the molecules (*a*) remains constant, (*b*) doubles, (*c*) quadruples, (*d*) increases by a factor of $\sqrt{2}$.

Determine the Concept The average speed of the molecules in an ideal gas depends on the square root of the kelvin temperature. Because $v_{\text{av}} \propto \sqrt{T}$, doubling the temperature while maintaining constant pressure increases the average speed by a factor of $\sqrt{2}$. $\boxed{(d)}$ is correct.

15 • **[SSM]** Suppose that you compress an ideal gas to half its original volume, while also halving its absolute temperature. During this process, the pressure of the gas (*a*) halves, (*b*) remains constant, (*c*) doubles, (*d*) quadruples.

Determine the Concept From the ideal-gas law, $PV = nRT$, halving both the temperature and volume of the gas leaves the pressure unchanged. $\boxed{(b)}$ is correct.

16 • The average translational kinetic energy of the molecules of a gas depends on (*a*) the number of moles and the temperature, (*b*) the pressure and the temperature, (*c*) the pressure only, (*d*) the temperature only.

Determine the Concept The average translational kinetic energy of the molecules of an ideal gas K_{av} depends on its temperature T according to $K_{\text{av}} = \frac{3}{2}kT$. $\boxed{(d)}$ is correct.

17 •• **[SSM]** Which speed is greater, the speed of sound in a gas or the rms speed of the molecules of the gas? Justify your answer, using the appropriate formulas, and explain why your answer is intuitively plausible.

Determine the Concept The rms speed of molecules of an ideal gas is given by $v_{\text{rms}} = \sqrt{\frac{3RT}{M}}$ and the speed of sound in a gas is given by $v_{\text{sound}} = \sqrt{\frac{\gamma RT}{M}}$.

The rms speed of the molecules of an ideal-gas is given by:

$$v_{\text{rms}} = \sqrt{\frac{3RT}{M}}$$

The speed of sound in a gas is given by:

$$v_{\text{sound}} = \sqrt{\frac{\gamma RT}{M}}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{v_{\text{rms}}}{v_{\text{sound}}}=\frac{\sqrt{\frac{3RT}{M}}}{\sqrt{\frac{\gamma RT}{M}}}=\sqrt{\frac{3}{\gamma}}$$

For a monatomic gas, $\gamma = 1.67$ and:

$$\frac{v_{\text{rms, monatomic}}}{v_{\text{sound}}}=\sqrt{\frac{3}{1.67}}=1.34$$

For a diatomic gas, $\gamma = 1.40$ and:

$$\frac{v_{\text{rms, diatomic}}}{v_{\text{sound}}}=\sqrt{\frac{3}{1.40}}=1.46$$

The rms speed is always somewhat greater than the speed of sound. However, it is only the component of the molecular velocities in the direction of propagation that is relevant to this issue. In addition, in a gas the mean free path is greater than the average intermolecular distance.

18 •• Imagine that you increase the temperature of a gas while holding its volume fixed. Explain in terms of molecular motion why the pressure of the gas on the walls of its container increases.

Determine the Concept The pressure is a measure of the average change in momentum per second of gas molecules colliding with the walls of the container. When the gas is heated, the average velocity and the average momentum of the molecules increase and, as a consequence, the pressure exerted by the molecules increases.

19 •• Imagine that you compress a gas while holding it at a fixed temperature (perhaps by immersing the container in cool water). Explain in terms of molecular motion why the pressure of the gas on the walls of its container increases.

Determine the Concept If the volume decreases the pressure increases because more molecules hit a unit of area of the walls in a given time. The fact that the temperature does not change tells us the molecular speed does not change with volume.

20 •• Oxygen has a molar mass of 32 g/mol and nitrogen has a molar mass of 28 g/mol. The oxygen and nitrogen molecules in a room have

(*a*) equal average translational kinetic energies, but the oxygen molecules have a larger average speed than the nitrogen molecules have.
(*b*) equal average translational kinetic energies, but the oxygen molecules have a smaller average speed than the nitrogen molecules have.

(*c*) equal average translational kinetic energies and equal average speeds.
(*d*) equal average speeds, but the oxygen molecules have a larger average translational kinetic energy than the nitrogen molecules have.
(*e*) equal average speeds, but the oxygen molecules have a smaller average translational kinetic energy than the nitrogen molecules have.
(*f*) None of the above.

Picture the Problem The average kinetic energies of the molecules are given by $K_{av} = \left(\frac{1}{2}mv^2\right)_{av} = \frac{3}{2}kT$. Assuming that the room's temperature distribution is uniform, we can conclude that the oxygen and nitrogen molecules have equal average kinetic energies. Because the oxygen molecules are more massive, they must be moving slower than the nitrogen molecules. $\boxed{(b)}$ is correct.

21 •• [SSM] Liquid nitrogen is relatively cheap, while liquid helium is relatively expensive. One reason for the difference in price is that while nitrogen is the most common constituent of the atmosphere, only small traces of helium can be found in the atmosphere. Use ideas from this chapter to explain why it is that only small traces of helium can be found in the atmosphere.

Determine the Concept The average molecular speed of He gas at 300 K is about 1.4 km/s, so a significant fraction of He molecules have speeds in excess of Earth's escape velocity (11.2 km/s). Thus, they "leak" away into space. Over time, the He content of the atmosphere decreases to almost nothing.

Estimation and Approximation

22 • Estimate the total number of air molecules in your classroom.

Picture the Problem The number of air molecules in your classroom is given by the ideal-gas law.

From the ideal-gas law, the number of molecules N in a given volume V at pressure P and temperature T is given by:

$$N = \frac{PV}{kT}$$

where k is Boltzmann's constant.

Assuming that a typical classroom is a rectangular parallelepiped, its volume is given by:

$$V = \ell wh$$

Substituting for V yields:

$$N = \frac{P\ell wh}{kT}$$

Assume atmospheric pressure, room temperature and that the room is 15 m square and 5 m high to obtain:

$$N = \frac{\left(1\,\text{atm}\times\dfrac{101.325\,\text{kPa}}{\text{atm}}\right)(15\,\text{m})(15\,\text{m})(5\,\text{m})}{\left(1.381\times10^{-23}\ \text{J/K}\right)(293\,\text{K})} \approx \boxed{3\times10^{28}}$$

23 •• Estimate the density of dry air at sea level on a warm summer day.

Picture the Problem We can use the definition of mass density, the definition of the molar mass of a gas, and the ideal-gas law to estimate the density of air at sea level on a warm day.

The density of air at sea level is given by:

$$\rho = \frac{m}{V}$$

The mass of the air molecules occupying a given volume is the product of the number of moles *n* and the molar mass *M* of the molecules. Substitute for *m* to obtain:

$$\rho = \frac{nM}{V}$$

From the ideal-gas law, the number of moles in a given volume depends on the pressure and temperature according to:

$$n = \frac{PV}{RT}$$

Substitute in the expression for ρ and simplify to obtain:

$$\rho = \frac{M}{V}\left(\frac{PV}{RT}\right) = \frac{PM}{RT}$$

Assuming atmospheric pressure, a temperature of 27°C (93°F), and 29 g/mol for the molar mass of air, substitute numerical values and evaluate ρ:

$$\rho = \frac{\left(1\,\text{atm}\times\dfrac{101.325\,\text{kPa}}{\text{atm}}\right)(29\ \text{g/mol})}{(8.314\ \text{J/mol}\cdot\text{K})(300\,\text{K})} = \boxed{1.2\ \text{kg/m}^3}$$

24 •• A stoppered test tube that has a volume of 10.0 mL has 1.00 mL of water at its bottom. The water has a temperature of 100ºC and is initially at a pressure of 1.00 atm. The test tube is held over a flame until the water has completely boiled away. Estimate the final pressure inside the test tube.

Picture the Problem Assuming the steam to be an ideal gas at a temperature of 373 K, we can use the ideal-gas law to estimate the pressure inside the test tube when the water is completely boiled away.

Using the ideal-gas law, relate the pressure inside the test tube to its volume and the temperature:

$$PV = \frac{m}{M}RT \Rightarrow P = \frac{m}{M}\frac{RT}{V}$$

Substitute numerical values and evaluate P:

$$P = \frac{0.00100\,\text{kg}}{18.0\times10^{-3}\,\frac{\text{kg}}{\text{m}^3}} \frac{\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(373\,\text{K})}{1.00\times10^{-5}\,\text{m}^3} = 1.723\times10^{7}\,\frac{\text{N}}{\text{m}^2}$$

$$= 1.723\times10^{7}\,\text{Pa}\times\frac{1\,\text{atm}}{101.3\,\text{kPa}} = \boxed{170\,\text{atm}}$$

25 •• **[SSM]** In Chapter 11, we found that the escape speed at the surface of a planet of radius R is $v_e = \sqrt{2gR}$, where g is the acceleration due to gravity at the surface of the planet. If the rms speed of a gas is greater than about 15 to 20 percent of the escape speed of a planet, virtually all of the molecules of that gas will escape the atmosphere of the planet.

(*a*) At what temperature is v_{rms} for O_2 equal to 15 percent of the escape speed for Earth?
(*b*) At what temperature is v_{rms} for H_2 equal to 15 percent of the escape speed for Earth?
(*c*) Temperatures in the upper atmosphere reach 1000 K. How does this help account for the low abundance of hydrogen in Earth's atmosphere?
(*d*) Compute the temperatures for which the rms speeds of O_2 and H_2 are equal to 15 percent of the escape speed at the surface of the moon, where g is about one-sixth of its value on Earth and R = 1738 km. How does this account for the absence of an atmosphere on the moon?

Picture the Problem We can find the escape temperatures for Earth and the moon by equating, in turn, $0.15v_e$ and v_{rms} of O_2 and H_2. We can compare these temperatures to explain the absence from Earth's upper atmosphere and from the surface of the moon. See Appendix C for the molar masses of O_2 and H_2.

(*a*) Express v_{rms} for O_2:

$$v_{rms,\,O_2} = \sqrt{\frac{3RT}{M_{O_2}}}$$

where R is the gas constant, T is the absolute temperature, and M_{O_2} is the molar mass of oxygen.

Equate $0.15v_e$ and v_{rms,O_2}:

$$0.15\sqrt{2gR_{earth}} = \sqrt{\frac{3RT}{M}}$$

Solve for T to obtain:

$$T = \frac{0.045gR_{earth}M}{3R} \quad (1)$$

Substitute numerical values and evaluate T for O_2:

$$T = \frac{0.045(9.81\,m/s^2)(6.37\times10^6\,m)(32.0\times10^{-3}\,kg/mol)}{3(8.314\,J/mol\cdot K)} = \boxed{3.60\times10^3\,K}$$

(*b*) Substitute numerical values and evaluate T for H_2:

$$T = \frac{0.045(9.81\,m/s^2)(6.37\times10^6\,m)(2.02\times10^{-3}\,kg/mol)}{3(8.314\,J/mol\cdot K)} = \boxed{230\,K}$$

(*c*) Because hydrogen is lighter than air it rises to the top of the atmosphere. Because the temperature is high there, a greater fraction of the molecules reach escape speed.

(*d*) Express equation (1) at the surface of the moon:

$$T = \frac{0.045g_{moon}R_{moon}M}{3R} = \frac{0.045(\frac{1}{6}g_{earth})R_{moon}M}{3R} = \frac{0.0025g_{earth}R_{moon}M}{R}$$

Substitute numerical values and evaluate T for O_2:

$$T = \frac{0.0025(9.81\,m/s^2)(1.738\times10^6\,m)(32.0\times10^{-3}\,kg/mol)}{8.314\,J/mol\cdot K} = \boxed{160\,K}$$

Substitute numerical values and evaluate T for H_2:

$$T = \frac{0.0025(9.81\,m/s^2)(1.738\times10^6\,m)(2.02\times10^{-3}\,kg/mol)}{8.314\,J/mol\cdot K} = \boxed{10\,K}$$

Because g is less on the moon, the escape speed is lower. Thus, a larger percentage of the molecules are moving at escape speed.

26 •• The escape speed for gas molecules in the atmosphere of Mars is 5.0 km/s and the surface temperature of Mars is typically 0ºC. Calculate the rms speeds for (*a*) H_2, (*b*) O_2, and (*c*) CO_2 at this temperature. (*d*) Are H_2, O_2, and CO_2 likely to be found in the atmosphere of Mars?

Picture the Problem We can use $v_{rms} = \sqrt{3RT/M}$ to calculate the rms speeds of H_2, O_2, and CO_2 at 273 K and then compare these speeds to 20% of the escape velocity on Mars to decide the likelihood of finding these gases in the atmosphere of Mars. See Appendix C for molar masses.

Express the rms speed of an atom as a function of the temperature:

$$v_{rms} = \sqrt{\frac{3RT}{M}}$$

(*a*) Substitute numerical values and evaluate v_{rms} for H_2:

$$v_{rms,H_2} = \sqrt{\frac{3(8.314\,\text{J/mol}\cdot\text{K})(273\,\text{K})}{2.02\times10^{-3}\,\text{kg/mol}}} = \boxed{1.84\,\text{km/s}}$$

(*b*) Evaluate v_{rms} for O_2:

$$v_{rms,O_2} = \sqrt{\frac{3(8.314\,\text{J/mol}\cdot\text{K})(273\,\text{K})}{32.0\times10^{-3}\,\text{kg/mol}}} = \boxed{461\,\text{m/s}}$$

(*c*) Evaluate v_{rms} for CO_2:

$$v_{rms,CO_2} = \sqrt{\frac{3(8.314\,\text{J/mol}\cdot\text{K})(273\,\text{K})}{44.0\times10^{-3}\,\text{kg/mol}}} = \boxed{393\,\text{m/s}}$$

(*d*) Calculate 20% of v_e for Mars:

$$0.20v_e = \tfrac{1}{5}(5.0\,\text{km/s}) = 1.0\,\text{km/s}$$

Because v is greater than v_{rms} for CO_2 but less than v_{rms} for H_2, O_2 and CO_2, but not H_2 should be present.

27 •• **[SSM]** The escape speed for gas molecules in the atmosphere of Jupiter is 60 km/s and the surface temperature of Jupiter is typically –150ºC. Calculate the rms speeds for (*a*) H_2, (*b*) O_2, and (*c*) CO_2 at this temperature. (*d*) Are H_2, O_2, and CO_2 likely to be found in the atmosphere of Jupiter?

Picture the Problem We can use $v_{rms} = \sqrt{3RT/M}$ to calculate the rms speeds of H_2, O_2, and CO_2 at 123 K and then compare these speeds to 20% of the escape speed on Jupiter to decide the likelihood of finding these gases in the atmosphere of Jupiter. See Appendix C for the molar masses of H_2, O_2, and CO_2.

Express the rms speed of an atom as a function of the temperature:

$$v_{\text{rms}} = \sqrt{\frac{3RT}{M}}$$

(*a*) Substitute numerical values and evaluate v_{rms} for H_2:

$$v_{\text{rms},H_2} = \sqrt{\frac{3(8.314\,\text{J/mol}\cdot\text{K})(123\,\text{K})}{2.02\times10^{-3}\,\text{kg/mol}}} = \boxed{1.23\,\text{km/s}}$$

(*b*) Evaluate v_{rms} for O_2:

$$v_{\text{rms},O_2} = \sqrt{\frac{3(8.314\,\text{J/mol}\cdot\text{K})(123\,\text{K})}{32.0\times10^{-3}\,\text{kg/mol}}} = \boxed{310\,\text{m/s}}$$

(*c*) Evaluate v_{rms} for CO_2:

$$v_{\text{rms},CO_2} = \sqrt{\frac{3(8.314\,\text{J/mol}\cdot\text{K})(123\,\text{K})}{44.0\times10^{-3}\,\text{kg/mol}}} = \boxed{264\,\text{m/s}}$$

(*d*) Calculate 20% of v_e for Jupiter:

$$0.20v_e = \tfrac{1}{5}(60\,\text{km/s}) = 12\,\text{km/s}$$

Because v_e is greater than v_{rms} for O_2, CO_2, and H_2, all three gasses should be found on Jupiter.

28 •• Estimate the average pressure on the front wall of a racquetball court, due to the collisions of the ball with the wall during a game. Use any reasonable numbers for the mass of the ball, its typical speed, and the dimensions of the court. Is the average pressure from the ball significant compared to that from the air?

Picture the Problem The average pressure exerted by the ball on the wall is the ratio of the average force it exerts on the wall to the area of the wall. The average force, in turn, is the rate at which the momentum of the ball changes during each collision with the wall. Assume that the mass of a racquetball is 100 g, that the court measures 5 m by 5 m, and that the speed of the racquetball is 10 m/s. We'll also assume that the interval Δt between collisions with the wall is 1 s.

The average pressure exerted on the wall by the racquetball is given by:

$$P_{\text{av}} = \frac{F_{\text{av}}}{A} = \frac{F_{\text{av}}}{wh}$$

where w and h are the width and height of the wall, respectively.

Assuming head-on collisions with the wall, the change in momentum of the ball during each collision is $2mv$ and the average force exerted by the ball on the wall is:

$$F_{av} = \frac{\Delta p}{\Delta t} = \frac{2mv}{\Delta t}$$

where Δt is the elapsed time between collisions of the ball with the wall.

Substituting for F_{av} yields:

$$P_{av} = \frac{2mv}{wh\Delta t}$$

Substitute numerical values and evaluate P_{av}:

$$P_{av} = \frac{2(.1\text{ kg})(10\text{ m/s})}{(5\text{ m})(5\text{ m})(1\text{ s})} = 0.08\text{ N/m}^2$$
$$\approx \boxed{0.1\text{ Pa}}$$

Express the ratio of P_{av} and P_{atm} to obtain:

$$\frac{P_{av}}{P_{atm}} \approx \frac{0.1\text{ Pa}}{10^5\text{ Pa}} = 10^{-6}$$

or

$$P_{av} \approx \boxed{10^{-6}P_{atm}}$$

and the average pressure from the ball is not significant compared to atmospheric pressure.

29 •• To a first approximation, the Sun consists of a gas of equal numbers of protons and electrons. (The masses of these particles can be found in Appendix B.) The temperature at the center of the Sun is about 1×10^7 K, and the density of the Sun is about 1×10^5 kg/m^3. Because the temperature is so high, the protons and electrons are separate particles (rather than being joined together to form hydrogen atoms). (*a*) Estimate the pressure at the center of the Sun. (*b*) Estimate the rms speeds of the protons and the electrons at the center of the Sun.

Picture the Problem We'll assume that we can model the plasma as an ideal gas, at least to a first approximation. Then we can apply the ideal gas law to an arbitrary volume of the material, say one cubic meter.

(*a*) To the extent that the plasma acts like an ideal gas, the pressure at the center of the Sun is given by:

$$P = \frac{nRT}{V}$$

The mass of our 1 m^3 volume of matter is 10^5 kg and this mass consists mostly of protons. One mole of protons has a mass of 1 g, so in 10^5 kg, the number of moles of protons would be:

$$n_{protons} = \frac{m_{protons}}{M_{protons}} = \frac{10^5\text{ kg}}{10^{-3}\text{ kg}} = 10^8\text{ mol}$$

or, counting electrons,

$$n = 2n_{protons} = 2\times10^8\text{ mol}$$

Substitute numerical values and evaluate P:

$$P = \frac{\left(2\times10^{8}\ \text{mol}\right)\left(8.314\ \text{J/mol}\cdot\text{K}\right)\left(10^{7}\ \text{K}\right)}{1\ \text{m}^{3}} \approx 2\times10^{16}\ \text{Pa}\times\frac{1\ \text{atm}}{101.325\ \text{kPa}} \approx \boxed{2\times10^{11}\ \text{atm}}$$

(*b*) To one significant figure, the average speed of the protons is the same as the rms speed:

$$v_{\text{rms, protons}} = \sqrt{\frac{3RT}{M_{\text{protons}}}}$$

Substitute numerical values and evaluate $v_{\text{rms, protons}}$:

$$v_{\text{rms, protons}} = \sqrt{\frac{3\left(8.314\ \text{J/mol}\cdot\text{K}\right)\left(10^{7}\ \text{K}\right)}{0.001\ \text{kg}}} = \boxed{5\times10^{5}\ \text{m/s}}$$

The rms speed of an electron at the center of the Sun is given by:

$$v_{\text{rms, electrons}} = \sqrt{\frac{3RT}{M_{\text{electrons}}}} = \sqrt{\frac{3RT}{\frac{1}{2000}M_{\text{protons}}}}$$

Substitute numerical values and evaluate $v_{\text{rms, electrons}}$:

$$v_{\text{rms, electrons}} = \sqrt{\frac{3\left(8.314\ \text{J/mol}\cdot\text{K}\right)\left(10^{7}\ \text{K}\right)}{\frac{1}{2000}\left(0.001\ \text{kg}\right)}} = \boxed{2\times10^{7}\ \text{m/s}}$$

Remarks: The huge pressure we calculated in (*a*) is *required* to support the tremendous weight of the rest of the sun. The very high speed we calculated for the plasma electrons is still an order-of-magnitude smaller than the speed of light.

30 •• You are designing a vacuum chamber for fabricating reflective coatings. Inside this chamber, a small sample of metal will be vaporized so that its atoms travel in straight lines (the effects of gravity are negligible during the brief time of flight) to a surface where they land to form a very thin film. The sample of metal is 30 cm from the surface to which the metal atoms will adhere. How low must the pressure in the chamber be so that the metal atoms only rarely collide with air molecules before they land on the surface?

Picture the Problem We can use the expression for the mean free path of a molecule to eliminate the number of molecules per unit volume n_V from the ideal-gas law. Assume that the air in the chamber is at room temperature (300 K) and that the average diameter of an air molecule is 4×10^{-10} m.

Apply the ideal gas law to express the pressure in terms of the number of molecules per unit volume and the temperature:

$$P = \frac{NkT}{V} = n_V kT$$

The mean free path of an air molecule is given by:

$$\lambda = \frac{1}{\sqrt{2}n_V \pi d^2} \Rightarrow n_V = \frac{1}{\sqrt{2}\lambda\pi d^2}$$

Substitute for n_V to obtain:

$$P = \frac{kT}{\sqrt{2}\lambda\pi d^2}$$

Substitute numerical values and evaluate P:

$$P = \frac{\left(1.381\times10^{-23}\ \text{J/K}\right)\left(300\ \text{K}\right)}{\sqrt{2}\left(30\ \text{cm}\right)\pi\left(4\times10^{-10}\ \text{m}\right)^2} \approx \boxed{20\ \text{mPa}}$$

31 ••• [SSM] In normal breathing conditions, approximately 5 percent of each exhaled breath is carbon dioxide. Given this information and neglecting any difference in water-vapor content, estimate the typical difference in mass between an inhaled breath and an exhaled breath.

Picture the Problem One breath (one's lung capacity) is about half a liter. The only thing that occurs in breathing is that oxygen is exchanged for carbon dioxide. Let's estimate that of the 20% of the air that is breathed in as oxygen, ¼ is exchanged for carbon dioxide. Then the mass difference between breaths will be 5% of a breath multiplied by the molar mass difference between oxygen and carbon dioxide and by the number of moles in a breath. Because this is an estimation problem, we'll use 32 g/mol as an approximation for the molar mass of oxygen and 44 g/mol as an approximation for the molar mass of carbon dioxide.

Express the difference in mass between an inhaled breath and an exhaled breath:

$$\Delta m = m_{O_2} - m_{CO_2} = f_{CO_2}\left(M_{CO_2} - M_{O_2}\right)n_{\text{breath}}$$

where f_{CO_2} is the fraction of the air breathed in that is exchanged for carbon dioxide.

The number of moles per breath is given by:

$$n_{\text{breath}} = \frac{V_{\text{breath}}}{22.4\ \text{L/mol}}$$

Substituting for n_{breath} yields:

$$\Delta m = f_{CO_2}\left(M_{CO_2} - M_{O_2}\right)\left(\frac{V_{\text{breath}}}{22.4\ \text{L/mol}}\right)$$

Substitute numerical values and evaluate Δm:

$$\Delta m = (0.05)(44\text{ g/mol} - 32\text{ g/mol})\frac{(0.5\text{ L})}{22.4\text{ L/mol}} \approx \boxed{0.01\text{ g}}$$

Temperature Scales

32 • A certain ski wax is rated for use between –12 and –7.0ºC. What is this temperature range on the Fahrenheit scale?

Picture the Problem We can use the temperature conversion equation $t_F = \frac{9}{5}t_C + 32$ to convert the Celsius temperatures to Fahrenheit temperatures and then use these results to find the temperature range on the Fahrenheit scale.

Convert –12ºC to the equivalent Fahrenheit temperature:

$$t_F = \tfrac{9}{5}(-12) + 32 = 10°\text{F}$$

Convert –7.0ºC to the equivalent Fahrenheit temperature:

$$t_F = \tfrac{9}{5}(-7.0) + 32 = 19°\text{F}$$

The temperature range on the Fahrenheit scale is approximately $\boxed{10°\text{F to } 19°\text{F}}$.

33 • **[SSM]** The melting point of gold is 1945.4ºF. Express this temperature in degrees Celsius.

Picture the Problem We can use the Fahrenheit-Celsius conversion equation to find this temperature on the Celsius scale.

Convert 1945.4°F to the equivalent Celsius temperature:

$$t_C = \tfrac{5}{9}(t_F - 32°) = \tfrac{5}{9}(1945.4° - 32°)$$
$$= \boxed{1063°\text{C}}$$

34 • A weather report indicates that the temperature is expected to drop by 15.0°C over the next four hours. By how many degrees on the Fahrenheit scale will the temperature drop?

Picture the Problem We can use the fact that 5 C° = 9 F° to set up a proportion that allows us to make easy interval conversions from either the Celsius or Fahrenheit scale to the other.

The proportion relating a temperature range on the Fahrenheit scale of a temperature range on the Celsius scale is:

$$\frac{\Delta t_F}{\Delta t_C} = \frac{9\ \text{F}°}{5\ \text{C}°} \Rightarrow \Delta t_F = \left(\frac{9\ \text{F}°}{5\ \text{C}°}\right)\Delta t_C$$

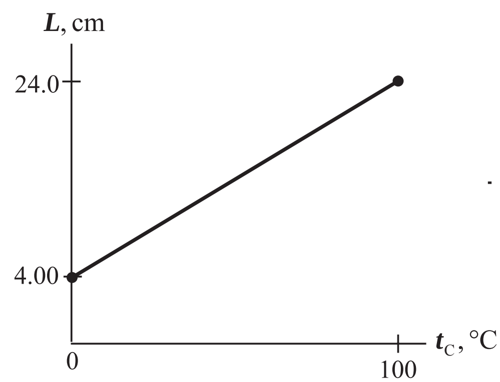
Substitute numerical values and evaluate Δt_F:

$$\Delta t_F = \left(\frac{9\ \text{F}°}{5\ \text{C}°}\right)(15.0\ \text{C}°) = \boxed{27.0\ \text{F}°}$$

35 • The length of the column of mercury in a thermometer is 4.00 cm when the thermometer is immersed in ice water at 1 atm of pressure, and 24.0 cm when the thermometer is immersed in boiling water at 1 atm of pressure. Assume that the length of the mercury column varies linearly with temperature. (*a*) Sketch a graph of the length of the mercury column versus temperature (in degrees Celsius). (*b*) What is the length of the column at room temperature (22.0ºC)? (*c*) If the mercury column is 25.4 cm long when the thermometer is immersed in a chemical solution, what is the temperature of the solution?

Picture the Problem We can use the equation of the graph plotted in (*a*) to (*b*) find the length of the mercury column at room temperature and (*c*) the temperature of the solution when the height of the mercury column is 25.4 cm.

(*a*) A graph of the length of the mercury column versus temperature (in degrees Celsius) is shown to the right. The equation of the line is:



$$L = \left(0.200\ \frac{\text{cm}}{°\text{C}}\right)t_C + 4.00\ \text{cm} \quad (1)$$

(*b*) Evaluate $L(22.0°\text{C})$

$$L = \left(0.200\ \frac{\text{cm}}{°\text{C}}\right)(22.0°\text{C}) + 4.00\ \text{cm}$$

$$= \boxed{8.40\ \text{cm}}$$

(*c*) Solve equation (1) for t_C to obtain:

$$t_C = \frac{L - 4.00\ \text{cm}}{0.200\ \frac{\text{cm}}{°\text{C}}}$$

Substitute numerical values and evaluate $t_C(25.4\,\text{cm})$:

$$t_C(25.4\,\text{cm}) = \frac{25.4\,\text{cm} - 4.00\,\text{cm}}{0.200\,\dfrac{\text{cm}}{°\text{C}}} = \boxed{107°\text{C}}$$

36 • The temperature of the interior of the Sun is about 1.0×10^7 K. What is this temperature in (*a*) Celsius degrees, and (*b*) Fahrenheit degrees?

Picture the Problem We can use the temperature conversion equations $t_F = \frac{9}{5}t_C + 32°$ and $t_C = T - 273.15\,\text{K}$ to convert 10^7 K to the Fahrenheit and Celsius temperatures.

Express the kelvin temperature in terms of the Celsius temperature:

$$T = t_C + 273.15\,\text{K}$$

(*a*) Solve for and evaluate t_C:

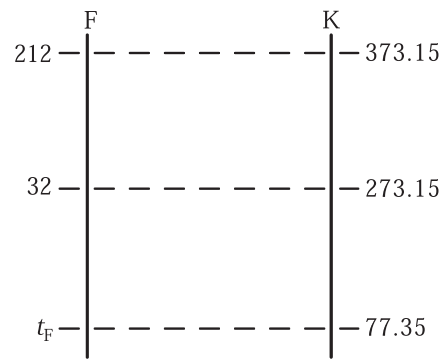
$$t_C = T - 273.15\,\text{K} = 1.0\times10^7\,\text{K} - 273.15\,\text{K} \approx \boxed{1.0\times10^7\,°\text{C}}$$

(*b*) Use the Celsius to Fahrenheit conversion equation to evaluate t_F:

$$t_F = \tfrac{9}{5}\left(1.0\times10^7\,°\text{C}\right) + 32° \approx \boxed{1.8\times10^7\,°\text{F}}$$

37 • The boiling point of nitrogen, N_2, is 77.35 K. Express this temperature in degrees Fahrenheit.

Picture the Problem While we could convert 77.35 K to a Celsius temperature and then convert the Celsius temperature to a Fahrenheit temperature, an alternative solution is to use the diagram to the right to set up a proportion for the direct conversion of the kelvin temperature to its Fahrenheit equivalent.



Use the diagram to set up the proportion:

$$\frac{32°\text{F} - t_F}{212°\text{F} - 32°\text{F}} = \frac{273.15\,\text{K} - 77.35\,\text{K}}{373.15\,\text{K} - 273.15\,\text{K}}$$

or

$$\frac{32°\text{F} - t_F}{180\,\text{F}°} = \frac{195.8}{100}$$

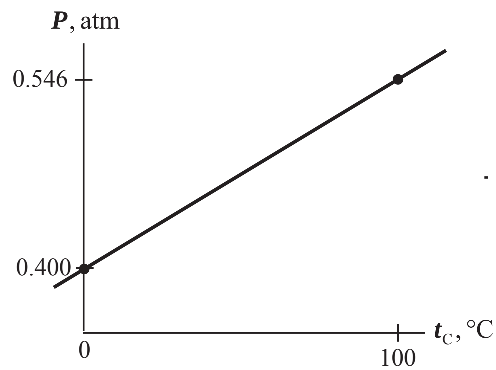
Solving for t_F yields:

$$t_F = 32°F - \frac{195.8}{100} \times 180\,F° = \boxed{-320°F}$$

38 • The pressure of a constant-volume gas thermometer is 0.400 atm at the ice point and 0.546 atm at the steam point. (a) Sketch a graph of pressure versus Celsius temperature for this thermometer. (*b*) When the pressure is 0.100 atm, what is the temperature? (*c*) What is the pressure at 444.6 ºC (the boiling point of sulfur)?

Picture the Problem We can use the equation of the graph plotted in (*a*) to (*b*) find the temperature when the pressure is 0.100 atm and (*c*) the pressure when the temperature is 444.6ºC.

(*a*) A graph of pressure (in atm) versus temperature (in degrees Celsius) for this thermometer is shown to the right. The equation of this graph is:



$$P = \left(1.46\times10^{-3}\,\frac{\text{atm}}{°\text{C}}\right)t_C + 0.400\,\text{atm}$$

(*b*) Solving for t_C yields:

$$t_C = \frac{P - 0.400\,\text{atm}}{1.46\times10^{-3}\,\frac{\text{atm}}{°\text{C}}}$$

Substitute numerical values and evaluate $t_C(0.100\,\text{atm})$:

$$t_C(0.100\,\text{atm}) = \frac{0.100\,\text{atm} - 0.400\,\text{atm}}{1.46\times10^{-3}\,\frac{\text{atm}}{°\text{C}}} = \boxed{-205°\text{C}}$$

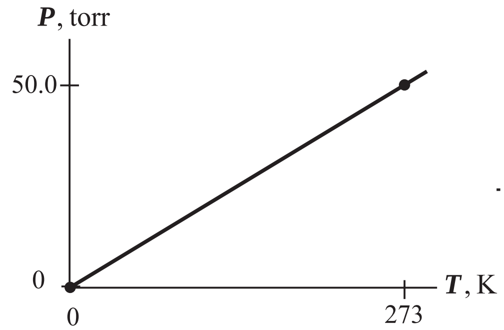
Substitute numerical values and evaluate $P(444.6°\text{C})$:

$$P(444.6°\text{C}) = \left(1.46\times10^{-3}\,\frac{\text{atm}}{°\text{C}}\right)(444.6°\text{C}) + 0.400\,\text{atm} = \boxed{1.05\,\text{atm}}$$

39 • **[SSM]** A constant-volume gas thermometer reads 50.0 torr at the triple point of water. (*a*) Sketch a graph of pressure vs. absolute temperature for this thermometer. (*b*) What will be the pressure when the thermometer measures a temperature of 300 K? (*c*) What ideal-gas temperature corresponds to a pressure of 678 torr?

Picture the Problem We can use the equation of the graph plotted in (*a*) to (*b*) find the pressure when the temperature is 300 K and (*c*) the ideal-gas temperature when the pressure is 678 torr.

(*a*) A graph of pressure (in torr) versus temperature (in kelvins) for this thermometer is shown to the right. The equation of this graph is:



$$P = \left(\frac{50.0\ \text{torr}}{273\ \text{K}}\right)T \qquad (1)$$

(*b*) Evaluate P when $T = 300$ K:

$$P(300\ \text{K}) = \left(\frac{50.0\ \text{torr}}{273\ \text{K}}\right)(300\ \text{K}) = \boxed{54.9\ \text{torr}}$$

(*c*) Solve equation (1) for T to obtain:

$$T = \left(\frac{273\ \text{K}}{50.0\ \text{torr}}\right)P$$

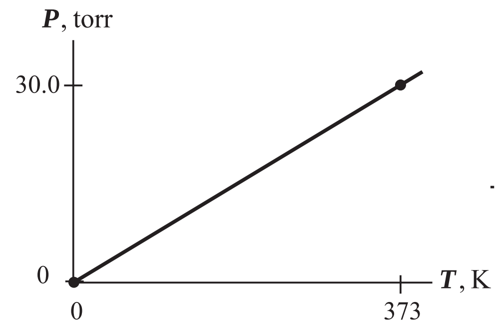
Evaluate $T(678\ \text{torr})$:

$$T(678\ \text{torr}) = \left(\frac{273\ \text{K}}{50.0\ \text{torr}}\right)(678\ \text{torr}) = \boxed{3.70\times10^{3}\ \text{K}}$$

40 • A constant-volume gas thermometer has a pressure of 30.0 torr when it reads a temperature of 373 K. (*a*) Sketch a graph of pressure vs. absolute temperature for this thermometer. (*b*) What is its triple-point pressure P_3? (*c*) What temperature corresponds to a pressure of 0.175 torr?

Picture the Problem We can use the equation of the graph plotted in (*a*) to (*b*) find the triple-point pressure P_3 and (*c*) the temperature when the pressure is 0.175 torr.

(*a*) A graph of pressure versus absolute temperature for this thermometer is shown to the right. The equation of this graph is:



$$P = \left(\frac{30.0\ \text{torr}}{373\ \text{K}}\right)T \quad (1)$$

(*b*) Solve for and evaluate the thermometer's triple-point (273.16 K) pressure:

$$P(273.16\ \text{K}) = \left(\frac{30.0\ \text{torr}}{373\ \text{K}}\right)(273.16\ \text{K}) = \boxed{22.0\ \text{torr}}$$

(*c*) Solve equation (1) for *T* to obtain:

$$T = \left(\frac{373\ \text{K}}{30.0\ \text{torr}}\right)P$$

Evaluate $T(0.175\ \text{torr})$:

$$T(0.175\ \text{torr}) = \left(\frac{373\ \text{K}}{30.0\ \text{torr}}\right)(0.175\ \text{torr}) = \boxed{2.18\ \text{K}}$$

41 • At what temperature do the Fahrenheit and Celsius temperature scales give the same reading?

Picture the Problem We can find the temperature at which the Fahrenheit and Celsius scales give the same reading by setting $t_F = t_C$ in the temperature-conversion equation.

Set $t_F = t_C$ in $t_C = \frac{5}{9}(t_F - 32°)$:

$$t_F = \tfrac{5}{9}(t_F - 32°)$$

Solve for and evaluate t_F:

$$t_C = t_F = \boxed{-40.0°\text{C}} = \boxed{-40.0°\text{F}}$$

Remarks: If you've not already thought of doing so, you might use your graphing calculator to plot t_C versus t_F and $t_F = t_C$ (a straight line at 45°) on the same graph. Their intersection is at (–40, –40).

42 • Sodium melts at 371 K. What is the melting point of sodium on the Celsius and Fahrenheit temperature scales?

Picture the Problem We can use the Celsius-to-absolute conversion equation to find 371 K on the Celsius scale and the Celsius-to-Fahrenheit conversion equation to find the Fahrenheit temperature corresponding to 371 K.

Express the absolute temperature as a function of the Celsius temperature: $T = t_C + 273.15\,\text{K}$

Solve for and evaluate t_C:

$$t_C = T - 273.15\,\text{K}$$
$$= 371\,\text{K} - 273.15\,\text{K} = \boxed{98°\text{C}}$$

Use the Celsius-to-Fahrenheit conversion equation to find t_F:

$$t_F = \tfrac{9}{5}t_C + 32° = \tfrac{9}{5}(97.9°) + 32°$$
$$= \boxed{208°\text{F}}$$

43 • The boiling point of oxygen at 1.00 atm is 90.2 K. What is the boiling point of oxygen at 1.00 atm on the Celsius and Fahrenheit scales?

Picture the Problem We can use the Celsius-to-absolute conversion equation to find 90.2 K on the Celsius scale and the Celsius-to-Fahrenheit conversion equation to find the Fahrenheit temperature corresponding to 90.2 K.

Express the absolute temperature as a function of the Celsius temperature: $T = t_C + 273.15\,\text{K}$

Solve for and evaluate t_C:

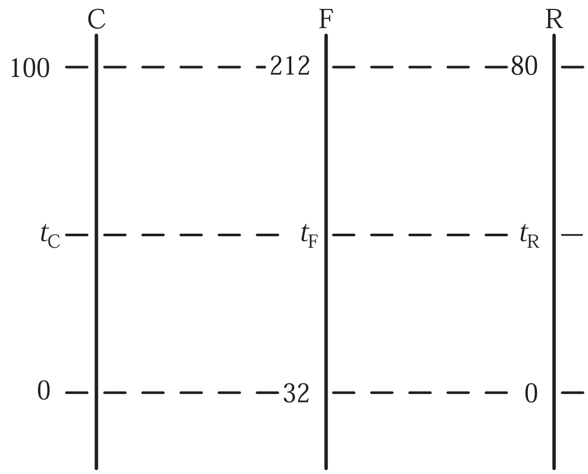
$$t_C = T - 273.15\,\text{K}$$
$$= 90.2\,\text{K} - 273.15\,\text{K} = \boxed{-183°\text{C}}$$

Use the Celsius-to-Fahrenheit conversion equation to find t_F:

$$t_F = \tfrac{9}{5}t_C + 32° = \tfrac{9}{5}(-183°) + 32°$$
$$= \boxed{-297°\text{F}}$$

44 •• On the Réaumur temperature scale, the melting point of ice is 0ºR and the boiling point of water is 80ºR. Derive expressions for converting temperatures on the Réaumur scale to the Celsius and Fahrenheit scales.

Picture the Problem We can use the following diagram to set up proportions that will allow us to convert temperatures on the Réaumur scale to Celsius and Fahrenheit temperatures.



Referring to the diagram, set up a proportion to convert temperatures on the Réaumur scale to Celsius temperatures:

$$\frac{t_C - 0°C}{100°C - 0°C} = \frac{t_R - 0°R}{80°R - 0°R}$$

Simplify to obtain:

$$\frac{t_C}{100} = \frac{t_R}{80} \Rightarrow t_C = \boxed{\tfrac{5}{4}t_R}$$

Referring to the diagram, set up a proportion to convert temperatures on the Réaumur scale to Fahrenheit temperatures:

$$\frac{t_F - 32°F}{212°F - 32°F} = \frac{t_R - 0°R}{80°R - 0°R}$$

Simplify to obtain:

$$\frac{t_F - 32}{180} = \frac{t_R}{80} \Rightarrow t_F = \boxed{\tfrac{9}{4}t_R + 32}$$

45 ••• [SSM] A thermistor is a solid-state device widely used in a variety of engineering applications. Its primary characteristic is that its electrical resistance varies greatly with temperature. Its temperature dependence is given approximately by $R = R_0e^{B/T}$, where R is in ohms (Ω), T is in kelvins, and R_0 and B are constants that can be determined by measuring R at calibration points such as the ice point and the steam point. (*a*) If R = 7360 Ω at the ice point and 153 Ω at the steam point, find R_0 and B. (*b*) What is the resistance of the thermistor at t = 98.6ºF? (*c*) What is the rate of change of the resistance with temperature (dR/dT) at the ice point and the steam point? (*d*) At which temperature is the thermistor most sensitive?

Picture the Problem We can use the temperature dependence of the resistance of the thermistor and the given data to determine R_0 and B. Once we know these quantities, we can use the temperature-dependence equation to find the resistance at any temperature in the calibration range. Differentiation of R with respect to T

will allow us to express the rate of change of resistance with temperature at both the ice point and the steam point temperatures.

(*a*) Express the resistance at the ice point as a function of temperature of the ice point:

$$7360\,\Omega = R_0 e^{B/273\,\text{K}} \quad (1)$$

Express the resistance at the steam point as a function of temperature of the steam point:

$$153\,\Omega = R_0 e^{B/373\,\text{K}} \quad (2)$$

Divide equation (1) by equation (2) to obtain:

$$\frac{7360\,\Omega}{153\,\Omega} = 48.10 = e^{B/273\,\text{K} - B/373\,\text{K}}$$

Solve for B by taking the logarithm of both sides of the equation:

$$\ln 48.1 = B\left(\frac{1}{273} - \frac{1}{373}\right)\text{K}^{-1}$$

and

$$B = \frac{\ln 48.1}{\left(\frac{1}{273} - \frac{1}{373}\right)\text{K}^{-1}} = 3.944 \times 10^3\ \text{K}$$

$$= \boxed{3.94 \times 10^3\ \text{K}}$$

Solve equation (1) for R_0 and substitute for B:

$$R_0 = \frac{7360\,\Omega}{e^{B/273\,\text{K}}} = (7360\,\Omega)e^{-B/273\,\text{K}}$$

$$= (7360\,\Omega)e^{-3.944\times10^3\,\text{K}/273\,\text{K}}$$

$$= 3.913 \times 10^{-3}\ \Omega$$

$$= \boxed{3.91 \times 10^{-3}\ \Omega}$$

(*b*) From (*a*) we have:

$$R = \left(3.913 \times 10^{-3}\ \Omega\right)e^{3.944\times10^3\,\text{K}/T}$$

Convert 98.6°F to kelvins to obtain:

$$T = 310\,\text{K}$$

Substitute for T to obtain:

$$R(310\,\text{K}) = \left(3.913 \times 10^{-3}\ \Omega\right)e^{3.944\times10^3\,\text{K}/310\,\text{K}}$$

$$= \boxed{1.31\,\text{k}\Omega}$$

(*c*) Differentiate R with respect to T to obtain:

$$\frac{dR}{dT} = \frac{d}{dT}\left(R_0 e^{B/T}\right) = R_0 e^{B/T}\frac{d}{dT}\left(\frac{B}{T}\right)$$

$$= \frac{-B}{T^2}R_0 e^{B/T} = -\frac{RB}{T^2}$$

Evaluate dR/dT at the ice point:

$$\left(\frac{dR}{dT}\right)_{\text{ice point}} = -\frac{(7360\,\Omega)(3.943\times10^{3}\text{ K})}{(273.16\text{K})^{2}} = \boxed{-389\,\Omega/\text{K}}$$

Evaluate dR/dT at the steam point:

$$\left(\frac{dR}{dT}\right)_{\text{steam point}} = -\frac{(153\,\Omega)(3.943\times10^{3}\text{ K})}{(373.16\text{K})^{2}} = \boxed{-4.33\,\Omega/\text{K}}$$

(*d*) The thermistor is more sensitive (has greater sensitivity) at lower temperatures.

The Ideal-Gas Law

46 • An ideal gas in a cylinder fitted with a piston (Figure 17-20) is held at fixed pressure. If the temperature of the gas increases from 50° to 100°C, by what factor does the volume change?

Picture the Problem Let the subscript 50 refer to the gas at 50°C and the subscript 100 to the gas at 100°C. We can apply the ideal-gas law for a fixed amount of gas to find the ratio of the final and initial volumes.

Apply the ideal-gas law for a fixed amount of gas:

$$\frac{P_{100}V_{100}}{T_{100}} = \frac{P_{50}V_{50}}{T_{50}}$$

or, because $P_{100} = P_{50}$,

$$\frac{V_{100}}{V_{50}} = \frac{T_{100}}{T_{50}}$$

Substitute numerical values and evaluate V_{100}/V_{50}:

$$\frac{V_{100}}{V_{50}} = \frac{(273.15+100)\text{K}}{(273.15+50)\text{K}} = \boxed{1.15}$$

or a 15% increase in volume.

47 • **[SSM]** A 10.0-L vessel contains gas at a temperature of 0.00ºC and a pressure of 4.00 atm. How many moles of gas are in the vessel? How many molecules?

Picture the Problem We can use the ideal-gas law to find the number of moles of gas in the vessel and the definition of Avogadro's number to find the number of molecules.

Apply the ideal-gas law to the gas:

$$PV = nRT \Rightarrow n = \frac{PV}{RT}$$

Substitute numerical values and evaluate n:

$$n = \frac{(4.00\,\text{atm})(10.0\,\text{L})}{(8.206\times10^{-2}\ \text{L}\cdot\text{atm/mol}\cdot\text{K})(273\,\text{K})} = 1.786\ \text{mol} = \boxed{1.79\,\text{mol}}$$

Relate the number of molecules N in the gas in terms of the number of moles n:

$$N = nN_{\text{A}}$$

Substitute numerical values and evaluate N:

$$N = (1.786\,\text{mol})(6.022\times10^{23}\ \text{molecules/mol}) = \boxed{1.08\times10^{24}\ \text{molecules}}$$

48 •• A pressure as low as 1.00×10^{-8} torr can be achieved using an oil diffusion pump. How many molecules are there in $1.00\ \text{cm}^3$ of a gas at this pressure if its temperature is 300 K?

Picture the Problem We can use the ideal-gas law to relate the number of molecules in the gas to its pressure, volume, and temperature.

Solve the ideal-gas law for the number of molecules in a gas as a function of its pressure, volume, and temperature:

$$N = \frac{PV}{kT}$$

Substitute numerical values and evaluate N:

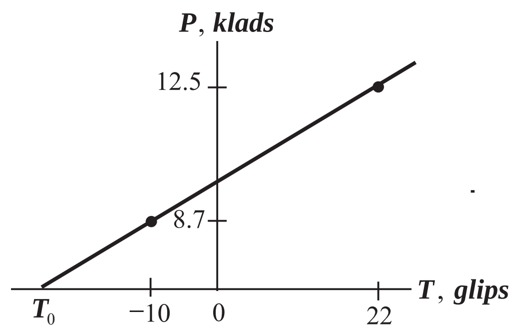
$$N = \frac{(1.00\times10^{-8}\ \text{torr})(133.32\,\text{Pa/torr})(1.00\times10^{-6}\ \text{m}^3)}{(1.381\times10^{-23}\ \text{J/K})(300\,\text{K})} = \boxed{3.22\times10^{8}}$$

49 •• You copy the following paragraph from a Martian physics textbook: "1 *snorf* of an ideal gas occupies a volume of 1.35 *zaks*. At a temperature of 22 *glips*, the gas has a pressure of 12.5 *klads*. At a temperature of –10 *glips*, the same gas now has a pressure of 8.7 *klads*." Determine the temperature of absolute zero in *glips*.

Picture the Problem Because the gas is ideal, its pressure is directly proportional to its temperature. Hence, a graph of P versus T will be linear and the linear equation relating P and T can be solved for the temperature corresponding to zero pressure. We'll assume that the data was taken at constant volume.

A graph of P, in *klads*, as function of T, in *glips*, is shown to the right. The equation of this graph is:

$$P = \left(\frac{3.8\ klads}{32\ glips}\right)T + 9.9\ klads$$



When $P = 0$:

$$0 = \left(\frac{3.8\ klads}{32\ glips}\right)T_0 + 9.9\ klads$$

Solve for T_0 to obtain:

$$T_0 = \boxed{-83\,glips}$$

50 •• A motorist inflates the tires of her car to a gauge pressure of 180 kPa on a day when the temperature is –8.0ºC. When she arrives at her destination, the tire pressure has increased to 245 kPa. What is the temperature of the tires if we assume that (*a*) the tires do not expand or (*b*) that the tires expand so the volume of the enclosed air increases by 7 percent?

Picture the Problem Let the subscript 1 refer to the tires when their gauge pressure is 180 kPa and the subscript 2 to conditions when their gauge pressure is 245 kPa. Assume that the air in the tires behaves as an ideal gas. Then, we can apply the ideal-gas law for a fixed amount of gas to relate the temperatures to the pressures and volumes of the tires.

(*a*) Apply the ideal-gas law for a fixed amount of gas to the air in the tires:

$$\frac{P_2V_2}{T_2} = \frac{P_1V_1}{T_1} \quad (1)$$

where the temperatures and pressures are absolute.

Solve for T_2:

$$T_2 = T_1\frac{P_2}{P_1}$$ because $V_1 = V_2$.

Substitute numerical values to obtain:

$$T_2 = (265\,\text{K})\frac{245\,\text{kPa} + 101\,\text{kPa}}{180\,\text{kPa} + 101\,\text{kPa}} = 326.3\,\text{K} = \boxed{53°\text{C}}$$

(*b*) Use equation (1) with $V_2 = 1.07\ V_1$. Solving for T_2 gives:

$$T_2 = \frac{P_2V_2}{P_1V_1}T_1 = (1.07)\left(\frac{P_2}{P_1}T_1\right)$$

Substitute numerical values and evaluate T_2:

$$T_2 = (1.07)(326.3\,\text{K}) = 349.1\,\text{K}$$
$$= \boxed{76°\text{C}}$$

51 •• A room is 6.0 m by 5.0 m by 3.0 m. (*a*) If the air pressure in the room is 1.0 atm and the temperature is 300 K, find the number of moles of air in the room. (*b*) If the temperature increases by 5.0 K and the pressure remains constant, how many moles of air leave the room?

Picture the Problem We can apply the ideal-gas law to find the number of moles of air in the room as a function of the temperature.

(*a*) Use the ideal-gas law to relate the number of moles of air in the room to the pressure, volume, and temperature of the air:

$$n = \frac{PV}{RT} \qquad (1)$$

Substitute numerical values and evaluate *n*:

$$n = \frac{(101.325\,\text{kPa})(6.0\,\text{m})(5.0\,\text{m})(3.0\,\text{m})}{(8.314\,\text{J/mol}\cdot\text{K})(300\,\text{K})}$$
$$= 3.66\times10^3\ \text{mol} = \boxed{3.7\times10^3\ \text{mol}}$$

(*b*) Letting n' represent the number of moles in the room when the temperature rises by 5 K, express the number of moles of air that leave the room:

$$\Delta n = n - n'$$

Apply the ideal-gas law to obtain:

$$n' = \frac{PV}{RT'} \qquad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{n'}{n} = \frac{T}{T'} \text{ and } n' = n\frac{T}{T'}$$

Substitute for n' to obtain:

$$\Delta n = n - n\frac{T}{T'} = n\left(1 - \frac{T}{T'}\right)$$

Substitute numerical values and evaluate Δn:

$$\Delta n = (3.66\times10^{3}\text{ mol})\left(1-\frac{300\text{ K}}{305\text{ K}}\right) = \boxed{60\text{ mol}}$$

52 •• Image that 10.0 g of liquid helium, initially at 4.20 K, evaporate into an empty balloon that is kept at 1.00 atm pressure. What is the volume of the balloon at (*a*) 25.0 K and (*b*) 293 K?

Picture the Problem Let the subscript 1 refer to helium gas at 4.2 K and the subscript 2 to the gas at 293 K. We can apply the ideal-gas law to find the volume of the gas at 4.2 K and a fixed amount of gas to find its volume at 293 K. See Appendix C for the molar mass of helium.

(*a*) Apply the ideal-gas law to the helium gas to express its volume:

$$V_1 = \frac{nRT_1}{P_1} = \frac{\frac{m}{M}RT_1}{P_1} = \frac{mRT_1}{MP_1}$$

Substitute numerical values and evaluate V_1:

$$V_1 = \frac{(10.0\text{ g})(0.08206\text{ L}\cdot\text{atm/mol}\cdot\text{K})(25.0\text{ K})}{(4.003\text{ g/mol})(1.00\text{ atm})} = 5.125\text{ L} = \boxed{5.13\text{ L}}$$

(*b*) Apply the ideal-gas law for a fixed amount of gas and solve for the volume of the helium gas at 293 K:

$$\frac{P_2V_2}{T_2} = \frac{P_1V_1}{T_1}$$

and, because $P_1 = P_2$,

$$V_2 = \frac{T_2}{T_1}V_1$$

Substitute numerical values and evaluate V_2:

$$V_2 = \frac{293\text{ K}}{25.0\text{ K}}(5.125\text{ L}) = \boxed{60.1\text{ L}}$$

53 •• A closed container with a volume of 6.00 L holds 10.0 g of liquid helium at 25.0 K and enough air to fill the rest of its volume at a pressure of 1.00 atm. The helium then evaporates and the container warms to room temperature (293 K). What is the final pressure inside the container?

Picture the Problem We can apply the law of partial pressures to find the final pressure inside the container. See Appendix C for the molar mass of helium and of air.

The final pressure inside the container is the sum of the partial pressures of helium gas and air:

$$P_{\text{final}} = P_{\text{He gas}} + P_{\text{air}} \quad (1)$$

The pressure exerted by the air molecules at room temperature is given by the ideal-gas law:

$$P_{\text{air}} = \frac{n_{\text{air}}RT}{V} = \frac{m_{\text{air}}RT}{M_{\text{air}}V} = \frac{\rho_{\text{air}}VRT}{M_{\text{air}}V} = \frac{\rho_{\text{air}}RT}{M_{\text{air}}}$$

The pressure exerted by the helium molecules at room temperature is also given by the ideal-gas law:

$$P_{\text{He gas}} = \frac{n_{\text{He}}RT}{V} = \frac{m_{\text{He}}RT}{M_{\text{He}}V}$$

Substituting in equation (1) yields:

$$P_{\text{final}} = \frac{m_{\text{He}}RT}{M_{\text{He}}V} + \frac{\rho_{\text{air}}RT}{M_{\text{air}}} = \left(\frac{m_{\text{He}}}{M_{\text{He}}V} + \frac{\rho_{\text{air}}}{M_{\text{air}}}\right)RT$$

Substitute numerical values and evaluate P_2:

$$P_{\text{final}} = \left(\frac{10.0\text{ g}}{\left(4.003\,\frac{\text{g}}{\text{mol}}\right)\left(6.00\text{ L}\times\frac{10^{-3}\text{ m}^3}{\text{L}}\right)} + \frac{1.293\,\frac{\text{kg}}{\text{m}^3}}{28.81\,\frac{\text{g}}{\text{mol}}}\right)\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(293\text{ K})$$

$$= 1.124\times10^{6}\text{ Pa}\times\frac{1\text{ atm}}{101.325\text{ kPa}} = \boxed{11.1\text{ atm}}$$

54 •• An automobile tire is filled to a gauge pressure of 200 kPa when its temperature is 20ºC. (Gauge pressure is the difference between the actual pressure and atmospheric pressure.) After the car has been driven at high speeds, the tire temperature increases to 50ºC. (*a*) Assuming that the volume of the tire does not change and that air behaves as an ideal gas, find the gauge pressure of the air in the tire. (*b*) Calculate the gauge pressure if the tire expands so the volume of the enclosed air increases by 10 percent.

Picture the Problem Let the subscript 1 refer to the tire when its temperature is 20°C and the subscript 2 to conditions when its temperature is 50°C. We can apply the ideal-gas law for a fixed amount of gas to relate the temperatures to the pressures of the air in the tire.

(*a*) Apply the ideal-gas law for a fixed amount of gas and solve for pressure at the higher temperature:

$$\frac{P_2V_2}{T_2}=\frac{P_1V_1}{T_1} \qquad (1)$$

and

$$P_2=\frac{T_2}{T_1}P_1$$

because $V_1 = V_2$

Substitute numerical values to obtain:

$$P_2=\frac{323\,\text{K}}{293\,\text{K}}\left(200\,\text{kPa}+101\,\text{kPa}\right)=332\,\text{kPa}$$

and

$$P_{2,\text{gauge}}=332\,\text{kPa}-101\,\text{kPa}=\boxed{231\,\text{kPa}}$$

(*b*) Solve equation (1) for P_2:

$$P_2=\frac{V_1T_2}{V_2T_1}P_1$$

Because $V_2 = 1.10\ V_1$:

$$P_2=\frac{V_1T_2}{1.10V_1T_1}P_1=\frac{T_2}{1.10T_1}P_1$$

Substitute numerical values and evaluate P_2 and $P_{2,\text{gauge}}$:

$$P_2=\frac{323\,\text{K}}{(1.10)(293\,\text{K})}\left(200\,\text{kPa}+101\,\text{kPa}\right)=302\,\text{kPa}$$

and

$$P_{2,\text{gauge}}=302\,\text{kPa}-101\,\text{kPa}=\boxed{201\,\text{kPa}}$$

55 •• [SSM] After nitrogen (N_2) and oxygen (O_2), the most abundant molecule in Earth's atmosphere is water, H_2O. However, the fraction of H_2O molecules in a given volume of air varies dramatically, from practically zero percent under the driest conditions to as high as 4 percent where it is very humid. (*a*) At a given temperature and pressure, would air be denser when its water vapor content is large or small? (*b*) What is the difference in mass, at room temperature and atmospheric pressure, between a cubic meter of air with no water vapor molecules, and a cubic meter of air in which 4 percent of the molecules are water vapor molecules?

Picture the Problem (*a*) At a given temperature and pressure, the ideal-gas law tells us that the total number of molecules per unit volume, *N*/*V*, is constant. The denser gas will, therefore, be the one in which the average mass *per molecule* is greater. (*b*) We can apply the ideal-gas law and use the relationship between the masses of the dry and humid air and their molar masses to find the difference in

mass, at room temperature and atmospheric pressure, between a cubic meter of air containing no water vapor, and a cubic meter of air containing 4% water vapor. See Appendix C for the molar masses of N_2, O_2, and H_2O.

(*a*) The molecular mass of N_2 is 28.014 u (see Appendix C), that of O_2 is 31.999 u, and that of H_2O is 18.0152 u. Because H_2O molecules are lighter than the predominant molecules in air, a given volume of air will be less dense when its water vapor content is higher.

(*b*) Express the difference in mass between a cubic meter of air containing no water vapor, and a cubic meter of air containing 4% water vapor:

$$\Delta m = m_{\text{dry}} - m_{\text{humid}}$$

The masses of the dry air and humid air are related to their molar masses according to:

$$m_{\text{dry}} = 0.04nM_{\text{dry}}$$

and

$$m_{\text{humid}} = 0.04nM_{\text{humid}}$$

Substitute for m_{dry} and m_{humid} and simplify to obtain:

$$\begin{aligned}\Delta m &= 0.04nM_{\text{dry}} - 0.04nM_{\text{humid}}\\ &= 0.04n\left(M_{\text{dry}} - M_{\text{humid}}\right)\end{aligned}$$

From the ideal-gas law we have:

$$n = \frac{P_{\text{atm}}V}{RT}$$

and so Δm can be written as

$$\Delta m = \frac{0.04P_{\text{atm}}V}{RT}\left(M_{\text{dry}} - M_{\text{humid}}\right)$$

Substitute numerical values (28.811 g/mol is an 80% nitrogen and 20% oxygen weighted average) and evaluate Δm:

$$\Delta m = \frac{(0.04)(101.325\ \text{kPa})\left(1.00\ \text{m}^3\right)}{(8.314\ \text{J/mol}\cdot\text{K})(300\ \text{K})}(28.811\ \text{g/mol} - 18.0152\ \text{g/mol}) \approx \boxed{18\ \text{g}}$$

Remarks: With 4% H_2O, the remaining 96% of the air is mostly a mixture of O_2 and N_2. With dry air, the 4% that was H_2O would be the same mix as the other 96%. Therefore, we need only consider the makeup of the 4%.

56 •• A scuba diver is 40 m below the surface of a lake, where the temperature is 5.0ºC. He releases an air bubble that has a volume of 15 cm^3. The bubble rises to the surface, where the temperature is 25ºC. Assume that the air in the bubble is always in thermal equilibrium with the surrounding water, and

assume that there is no exchange of molecules between the bubble and the surrounding water. What is the volume of the bubble right before it breaks the surface? *Hint: Remember that the pressure also changes*.

Picture the Problem Let the subscript 1 refer to the conditions at the bottom of the lake and the subscript 2 to the surface of the lake and apply the ideal-gas law for a fixed amount of gas.

Apply the ideal-gas law for a fixed amount of gas:

$$\frac{P_2V_2}{T_2}=\frac{P_1V_1}{T_1}\Rightarrow V_2=\frac{V_1T_2P_1}{T_1P_2}$$

The pressure at the bottom of the lake is the sum of the pressure at its surface (atmospheric) and the pressure due to the depth of the lake:

$$P_1=P_{\text{atm}}+\rho gh$$

Substituting for P_1 yields:

$$V_2=\frac{V_1T_2\left(P_{\text{atm}}+\rho gh\right)}{T_1P_2}$$

Substitute numerical values and evaluate V_2:

$$V_2=\frac{\left(15\text{ cm}^3\right)\left(298\text{ K}\right)\left[101.325\text{ kPa}+\left(1.00\times10^3\text{ kg/m}^3\right)\left(9.81\text{ m/s}^2\right)\left(40\text{ m}\right)\right]}{\left(278\text{ K}\right)\left(101.325\text{ kPa}\right)}$$
$$=\boxed{78\text{ cm}^3}$$

57 •• [SSM] A hot-air balloon is open at the bottom. The balloon has a volume of 446 m^3 is filled with air with an average temperature of 100°C. The air outside the balloon has a temperature of 20.0°C and a pressure of 1.00 atm. How large a payload (including the envelope of the balloon itself) can the balloon lift? Use 29.0 g/mol for the molar mass of air. (Neglect the volume of both the payload and the envelope of the balloon.)

Picture the Problem Assume that the volume of the balloon is not changing. Then the air inside and outside the balloon must be at the same pressure of about 1.00 atm. The contents of the balloon are the air molecules inside it. We can use Archimedes principle to express the buoyant force on the balloon and we can find the weight of the air molecules inside the balloon. You'll need to determine the molar mass of air. See Appendix C for the molar masses of oxygen and nitrogen.

Express the net force on the balloon and its contents:

$$F_{\text{net}}=B-w_{\text{air inside the balloon}} \qquad (1)$$

Using Archimedes principle, express the buoyant force on the balloon:

$B = w_{\text{displaced fluid}} = m_{\text{displaced fluid}}g$

or

$B = \rho_{\text{o}} V_{\text{balloon}} g$

where ρ_{o} is the density of the air outside the balloon.

Express the weight of the air inside the balloon:

$w_{\substack{\text{air inside}\\ \text{the balloon}}} = \rho_{\text{i}} V_{\text{balloon}} g$

where ρ_{i} is the density of the air inside the balloon.

Substitute in equation (1) for B and $w_{\substack{\text{air inside}\\ \text{the balloon}}}$ to obtain:

$$F_{\text{net}} = \rho_{\text{o}} V_{\text{balloon}} g - \rho_{\text{i}} V_{\text{balloon}} g = (\rho_{\text{o}} - \rho_{\text{i}}) V_{\text{balloon}} g \qquad (2)$$

Express the densities of the air molecules in terms of their number densities, molecular mass, and Avogadro's number:

$$\rho = \frac{M}{N_{\text{A}}}\left(\frac{N}{V}\right)$$

Using the ideal-gas law, relate the number density of air N/V to its temperature and pressure:

$$PV = NkT \text{ and } \frac{N}{V} = \frac{P}{kT}$$

Substitute for $\frac{N}{V}$ to obtain:

$$\rho = \frac{M}{N_{\text{A}}}\left(\frac{P}{kT}\right)$$

Substitute in equation (2) and simplify to obtain:

$$F_{\text{net}} = \frac{MP}{N_{\text{A}}k}\left(\frac{1}{T_{\text{o}}} - \frac{1}{T_{\text{i}}}\right) V_{\text{balloon}} g$$

Assuming that the average molar mass of air is 29.0 g/mol, substitute numerical values and evaluate F_{net}:

$$F_{\text{net}} = \frac{(29.0\text{ g/mol})(101.325\text{ kPa})\left(\frac{1}{293\text{ K}} - \frac{1}{373\text{ K}}\right)(446\text{ m}^3)(9.81\text{ m/s}^2)}{(6.022\times10^{23}\text{ particles/mol})(1.381\times10^{-23}\text{ J/K})} = \boxed{1.1\text{ kN}}$$

58 ••• A helium balloon is used to lift a load of 110 N. The weight of the envelope of the balloon is 50.0 N and the volume of the helium when the balloon is fully inflated is 32.0 m^3. The temperature of the air is 0ºC and the atmospheric pressure is 1.00 atm. The balloon is inflated with a sufficient amount of helium gas that the net upward force on the balloon and its load is 30.0 N. Neglect any

effects due to the changes of temperature as the altitude changes. (*a*) How many moles of helium gas are contained in the balloon? (*b*) At what altitude will the balloon be fully inflated? (*c*) Does the balloon ever reach the altitude at which it is fully inflated? (*d*) If the answer to (*c*) is ″Yes,″ what is the maximum altitude attained by the balloon?

Picture the Problem (*a*) We can find the number of moles of helium gas in the balloon by applying the ideal-gas law to relate *n* to the pressure, volume, and temperature of the helium and Archimedes principle to find the volume of the helium. In Part (*b*), we can apply the result of Problem 13-91 to relate atmospheric pressure to altitude and use the ideal-gas law to determine the pressure of the gas when the balloon is fully inflated. In Part (*c*), we'll find the net force acting on the balloon at the altitude at which it is fully inflated in order to decide whether it can rise to that altitude.

(*a*) Apply the ideal-gas law to the helium in the balloon and solve for *n*:

$$n = \frac{PV}{RT} \qquad (1)$$

Relate the net force on the balloon to its weight:

$$F_B - w_{skin} - w_{load} - w_{He} = 30\,\text{N}$$

Use Archimedes principle to express the buoyant force on the balloon in terms of the volume of the balloon:

$$F_B = w_{displaced\,air} = \rho_{air} V g$$

Substitute to obtain:

$$\rho_{air} V g - w_{skin} - w_{load} - \rho_{He} V g = 30.0\,\text{N}$$

Solve for the volume of the helium:

$$V = \frac{30.0\,\text{N} + w_{skin} + w_{load}}{(\rho_{air} - \rho_{He})g}$$

Substituting for *V* in equation (1) yields:

$$n = \frac{P(30.0\,\text{N} + w_{skin} + w_{load})}{RT(\rho_{air} - \rho_{He})g}$$

Substitute numerical values and evaluate n:

$$n = \frac{(1.00\,\text{atm})(30.0\,\text{N}+50.0\,\text{N}+110\,\text{N})\left(\dfrac{1\,\text{L}}{10^{-3}\,\text{m}^3}\right)}{(8.206\times10^{-2}\,\text{L}\cdot\text{atm/mol}\cdot\text{K})(273\,\text{K})(1.293\,\text{kg/m}^3-0.179\,\text{kg/m}^3)(9.81\,\text{m/s}^2)}$$
$$= \boxed{776\,\text{mol}}$$

(b) Using the result of Problem 13-91, express the variation in atmospheric pressure with altitude:

$$P(h) = P_0 e^{-Ch}$$
where $C = 0.13\,\text{km}^{-1}$.

Solving for h yields:

$$h = \frac{1}{C}\ln\left[\frac{P_0}{P(h)}\right] \qquad (2)$$

Using the ideal-gas law, express P:

$$P = \frac{nRT}{V}$$

Substitute for P in equation (2) and simplify to obtain:

$$h = \frac{1}{C}\ln\left[\frac{P_0}{\dfrac{nRT}{V}}\right] = \frac{1}{C}\ln\left[\frac{P_0V}{nRT}\right]$$

Substitute numerical values and evaluate h:

$$h = \left(\frac{1}{0.13\,\text{km}^{-1}}\right)\ln\left[\frac{(1.00\,\text{atm})\left(32.0\,\text{m}^3\times\dfrac{1\,\text{L}}{10^{-3}\,\text{m}^3}\right)}{(776\,\text{mol})(8.206\times10^{-2}\,\text{L}\cdot\text{atm/mol}\cdot\text{K})(273\,\text{K})}\right]$$
$$= 4.69\,\text{km} = \boxed{4.7\,\text{km}}$$

(c) Express the condition that must be satisfied if the balloon is to reach its fully inflated altitude:

$$F_{\text{net}} = F_{\text{B}} - w_{\text{tot}} \geq 0 \qquad (3)$$

The total weight is the sum of the weights of the load, balloon skin, and helium:

$$w_{\text{tot}} = w_{\text{load}} + w_{\text{skin}} + w_{\text{He}}$$
or, because $w_{\text{He}} = \rho_{\text{He}}Vg$,
$$w_{\text{tot}} = w_{\text{load}} + w_{\text{skin}} + \rho_{\text{He}}Vg$$

Express the buoyant force on the balloon at $h = 4.84$ km:

$$F_B = \rho_{\text{air},h} Vg \qquad (4)$$

Express the dependence of the density of the air on atmospheric pressure:

$$\frac{P}{P_0} = \frac{\rho_{\text{air},h}}{\rho_{\text{air}}} \Rightarrow \rho_{\text{air},h} = \frac{P}{P_0}\rho_{\text{air}} \qquad (5)$$

Substitute for $\rho_{\text{air},h}$ in equation (4) to obtain:

$$F_B = \frac{P}{P_0}\rho_{\text{air}} Vg$$

Substitute for w_{tot} and F_B in equation (3) and simplify to obtain:

$$F_{\text{net}} = \frac{P}{P_0} Vg(\rho_{\text{air}} - \rho_{\text{He}}) - w_{\text{load}} - w_{\text{skin}}$$

or, because $P(h) = P_0 e^{-Ch}$,

$$F_{\text{net}} = e^{-Ch} Vg(\rho_{\text{air}} - \rho_{\text{He}}) - w_{\text{load}} - w_{\text{skin}}$$

Substitute numerical values and evaluate F_{net}:

$$F_{\text{net}} = e^{-(0.13\,\text{km}^{-1})(4.69\,\text{km})}(32.0\,\text{m}^3)(9.81\,\text{m/s}^2)(1.293\,\text{kg/m}^3 - 0.179\,\text{kg/m}^3) - 110\,\text{N} - 50\,\text{N} = 30\,\text{N}$$

Because $F_{\text{net}} = 30$ N > 0, the balloon will rise higher than the altitude at which it is fully inflated.

(*d*) The balloon will rise until the net force acting on it is zero. Because the buoyant force depends on the density of the air, the balloon will rise until the density of the air has decreased sufficiently for the buoyant force to just equal the total weight of the balloon.

Substitute equation (5) in equation (2) to obtain:

$$h = \frac{1}{C}\ln\frac{\rho_{\text{air}}}{\rho_{\text{air},h}}$$

Using equation (4), express the density of the air in terms of F_B:

$$\rho_{\text{air},h} = \frac{F_B}{Vg}$$

Substituting for $\rho_{\text{air},h}$ and simplifying yields:

$$h = \frac{1}{C}\ln\left[\frac{\rho_{\text{air}}}{\frac{F_B}{Vg}}\right] = \frac{1}{C}\ln\left[\frac{Vg\rho_{\text{air}}}{F_B}\right]$$

Substitute numerical values and evaluate h:

$$h = \left(\frac{1}{0.13\ \text{km}^{-1}}\right)\ln\left[\frac{(32.0\ \text{m}^3)(9.81\ \text{m/s}^2)(1.293\ \text{kg/m}^3)}{190.5\ \text{N}}\right] = \boxed{5.8\ \text{km}}$$

Kinetic Theory of Gases

59 • **[SSM]** (*a*) One mole of argon gas is confined to a 1.0-liter container at a pressure of 10 atm. What is the rms speed of the argon atoms? (*b*) Compare your answer to the rms speed for helium atoms under the same conditions.

Picture the Problem We can express the rms speeds of argon and helium atoms by combining $PV = nRT$ and $v_{\text{rms}} = \sqrt{3RT/M}$ to obtain an expression for v_{rms} in terms of *P*, *V*, and *M*. See Appendix C for the molar masses of argon and helium.

Express the rms speed of an atom as a function of the temperature and its molar mass:

$$v_{\text{rms}} = \sqrt{\frac{3RT}{M}}$$

From the ideal-gas law we have:

$$RT = \frac{PV}{n}$$

Substitute for *RT* to obtain:

$$v_{\text{rms}} = \sqrt{\frac{3PV}{nM}}$$

(*a*) Substitute numerical values and evaluate v_{rms} for argon atoms:

$$\boldsymbol{v}_{\text{rms, Ar}} = \sqrt{\frac{3(10\ \text{atm})(101.325\ \text{kPa/atm})(1.0\times10^{-3}\ \text{m}^3)}{(1\ \text{mol})(39.948\times10^{-3}\ \text{kg/mol})}} = \boxed{0.28\ \text{km/s}}$$

(*b*) Substitute numerical values and evaluate v_{rms} for helium atoms:

$$v_{\text{rms, He}} = \sqrt{\frac{3(10\ \text{atm})(101.325\ \text{kPa/atm})(1.0\times10^{-3}\ \text{m}^3)}{(1\ \text{mol})(4.003\times10^{-3}\ \text{kg/mol})}} = \boxed{0.87\ \text{km/s}}$$

The rms speed of argon atoms is slightly less than one third the rms speed of helium atoms.

60 • Find the total translational kinetic energy of the molecules of 1.0 L of oxygen gas at a temperature of 0.0ºC and a pressure of 1.0 atm.

Picture the Problem We can express the total translational kinetic energy of the oxygen gas by combining $K = \frac{3}{2}nRT$ and the ideal-gas law to obtain an expression for K in terms of the pressure and volume of the gas.

Relate the total translational kinetic energy of translation to the temperature of the gas:

$$K = \tfrac{3}{2}nRT$$

Using the ideal-gas law, substitute for nRT to obtain:

$$K = \tfrac{3}{2}PV$$

Substitute numerical values and evaluate K:

$$K = \tfrac{3}{2}(101.325\,\text{kPa})\left(1.0\,\text{L}\times\frac{10^{-3}\,\text{m}^3}{\text{L}}\right) = \boxed{0.15\,\text{kJ}}$$

61 • Estimate the rms speed and the average kinetic energy of a hydrogen atom in a gas at a temperature of 1.0×10^7 K. (At this temperature, which is approximately the temperature in the interior of a star, hydrogen atoms are ionized and become protons.)

Picture the Problem Because we're given the temperature of the hydrogen atom and know its molar mass, we can find its rms speed using $v_{\text{rms}} = \sqrt{3RT/M}$ and its average kinetic energy from $K_{\text{av}} = \frac{3}{2}kT$. See Appendix C for the molar mass of hydrogen.

Relate the rms speed of a hydrogen atom to its temperature and molar mass:

$$v_{\text{rms}} = \sqrt{\frac{3RT}{M_{\text{H}}}}$$

Substitute numerical values and evaluate v_{rms}:

$$v_{\text{rms}} = \sqrt{\frac{3(8.314\,\text{J/mol}\cdot\text{K})(1.0\times10^7\,\text{K})}{1.0079\times10^{-3}\,\text{kg/mol}}} = \boxed{5.0\times10^5\,\text{m/s}}$$

Express the average kinetic energy of the hydrogen atom as a function of its temperature:

$$K_{\text{av}} = \tfrac{3}{2}kT$$

Substitute numerical values and evaluate K_{av}:

$$K_{\text{av}} = \tfrac{3}{2}(1.381\times10^{-23}\,\text{J/K})(1.0\times10^7\,\text{K}) = \boxed{2.1\times10^{-16}\,\text{J}}$$

62 • Liquid helium has a temperature of only 4.20 K and is in equilibrium with its vapor at atmospheric pressure. Calculate the rms speed of a helium atom in the vapor at this temperature, and comment on the result.

Picture the Problem The rms speed of helium atoms is given by $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M_{\text{He}}}}$.

See Appendix C for the molar mass of helium.

The rms speed of helium atoms is given by:

$$v_{\text{rms}} = \sqrt{\frac{3RT}{M_{\text{He}}}}$$

Substitute numerical values and evaluate v_{rms}:

$$v_{\text{rms}} = \sqrt{\frac{3(8.314\ \text{J/mol}\cdot\text{K})(4.20\ \text{K})}{4.003\ \text{g/mol}}} = \boxed{162\ \text{m/s}}$$

Thermal speeds, even at temperatures as low as 4.20 K, are very large compared to most of the speeds we experience directly.

63 • Show that the mean free path for a molecule in an ideal gas at temperature T and pressure P is given by $\lambda = kT/\sqrt{2}P\pi d^2$.

Picture the Problem We can combine $\lambda = \dfrac{1}{\sqrt{2}n_v \pi d^2}$ and $PV = NkT$ to express the mean free path for a molecule in an ideal gas in terms of the pressure and temperature.

Express the mean free path of a molecule in an ideal gas:

$$\lambda = \frac{1}{\sqrt{2}n_v \pi d^2} \qquad (1)$$

where

$$n_v = \frac{N}{V}$$

From Equation 17-7:

$$V = \frac{NkT}{P}$$

Substitute for V in the expression for n_v to obtain:

$$n_v = \frac{N}{\dfrac{NkT}{P}} = \frac{P}{kT}$$

Substitute for n_v in equation (1) to obtain:

$$\lambda = \boxed{\frac{kT}{\sqrt{2}P\pi d^2}}$$

64 •• State-of-the-art vacuum equipment can attain pressures as low as 7.0×10^{-11} Pa. Suppose that a chamber contains helium at this pressure and at room temperature (300 K). Estimate the mean free path and the collision time for helium in the chamber. Assume the diameter of a helium atom is 1.0×10^{-10} m.

Picture the Problem We can find the collision time from the mean free path and the average (rms) speed of the helium molecules. We can use the result of Problem 63 to find the mean free path of the molecules and $v_{\text{rms}} = \sqrt{3RT/M}$ to find the average speed of the molecules. See Appendix C for the molar mass of helium.

Express the collision time in terms of the mean free path for and the average speed of a helium molecule:

$$\tau = \frac{\lambda}{v_{\text{av}}} \approx \frac{\lambda}{v_{\text{rms}}} \qquad (1)$$

From Problem 63, the mean free path of the gas is given by:

$$\lambda = \frac{kT}{\sqrt{2}P\pi d^2}$$

Substitute numerical values and evaluate the mean free path λ:

$$\lambda = \frac{\left(1.381\times10^{-23}\ \text{J/K}\right)\left(300\ \text{K}\right)}{\sqrt{2}\left(7.0\times10^{-11}\ \text{Pa}\right)\pi\left(1.0\times10^{-10}\ \text{m}\right)^2} = 1.332\times10^{9}\ \text{m} = \boxed{1.3\times10^{9}\ \text{m}}$$

Express the rms speed of the helium molecules:

$$v_{\text{rms}} = \sqrt{\frac{3RT}{M_{\text{He}}}}$$

Substitute for v_{rms} in equation (1) and simplify to obtain:

$$\tau = \frac{\lambda}{\sqrt{\dfrac{3RT}{M_{\text{He}}}}} = \lambda\sqrt{\frac{M_{\text{He}}}{3RT}}$$

Substitute numerical values and evaluate τ:

$$\tau = \left(1.332\times10^{9}\ \text{m}\right)\sqrt{\frac{4.007\ \text{g/mol}}{3\left(8.314\ \text{J/mol}\cdot\text{K}\right)\left(300\ \text{K}\right)}} = \boxed{9.7\times10^{5}\ \text{s}}$$

65 •• **[SSM]** Oxygen (O_2) is confined to a cube-shaped container 15 cm on an edge at a temperature of 300 K. Compare the average kinetic energy of a molecule of the gas to the change in its gravitational potential energy if it falls 15 cm (the height of the container).

Picture the Problem We can use $K = \frac{3}{2}kT$ and $\Delta U = mgh = Mgh/N_A$ to express the ratio of the average kinetic energy of a molecule of the gas to the change in its gravitational potential energy if it falls from the top of the container to the bottom. See Appendix C for the molar mass of oxygen.

Express the average kinetic energy of a molecule of the gas as a function of its temperature:

$$K_{av} = \tfrac{3}{2}kT$$

Letting h represent the height of the container, express the change in the potential energy of a molecule as it falls from the top of the container to the bottom:

$$\Delta U = mgh = \frac{M_{O_2}gh}{N_A}$$

Express the ratio of K_{av} to ΔU and simplify to obtain:

$$\frac{K_{av}}{\Delta U} = \frac{\frac{3}{2}kT}{\frac{M_{O_2}gh}{N_A}} = \frac{3N_A kT}{2M_{O_2}gh}$$

Substitute numerical values and evaluate $K_{av}/\Delta U$:

$$\frac{K_{av}}{\Delta U} = \frac{3\left(6.022\times10^{23}\text{ particles/mol}\right)\left(1.381\times10^{-23}\text{ J/K}\right)\left(300\text{ K}\right)}{2\left(32.0\times10^{-3}\text{ kg/mol}\right)\left(9.81\text{ m/s}^2\right)\left(0.15\text{ m}\right)} = \boxed{7.9\times10^{4}}$$

*The Distribution of Molecular Speeds

66 •• Use calculus to show that $f(v)$, given by Equation 17-36, has its maximum value at a speed $v = \sqrt{2kT/m}$.

Picture the Problem Equation 17-36 gives the Maxwell-Boltzmann speed distribution. Setting its derivative with respect to v equal to zero will tell us where the function's extreme values lie.

Differentiate Equation 17-36 with respect to v:

$$\frac{df}{dv}=\frac{d}{dv}\left[\frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2}v^2e^{-mv^2/2kT}\right]$$
$$=\frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2}\left(2v-\frac{mv^3}{kT}\right)e^{-mv^2/2kT}$$

Set $df/dv = 0$ for extrema and solve for v:

$$2v-\frac{mv^3}{kT}=0\Rightarrow\ v=\boxed{\sqrt{\frac{2kT}{m}}}$$

Examination of the graph of $f(v)$ makes it clear that this extreme value is, in fact, a maximum. See Figure 17-17 and note that it is concave downward at $v=\sqrt{2kT/m}$.

Remarks: An alternative to the examination of $f(v)$ in order to conclude that $v=\sqrt{2kT/m}$ maximizes the Maxwell-Boltzmann speed distribution function is to show that $d^2f/dv^2 < 0$ at $v=\sqrt{2kT/m}$.

67 •• [SSM] The fractional distribution function $f(v)$ is defined in Equation 17-36. Because $f(v)\,dv$ gives the fraction of molecules that have speeds in the range between v and $v + dv$, the integral of $f(v)\,dv$ over all the possible ranges of speeds must equal 1. Given that the integral $\int_0^\infty v^2e^{-av^2}dv=\frac{\sqrt{\pi}}{4}a^{-3/2}$, show that $\int_0^\infty f(v)dv=1$, where $f(v)$ is given by Equation 17-36.

Picture the Problem We can show that $f(v)$ is normalized by using the given integral to integrate it over all possible speeds.

Express the integral of Equation 17-36:

$$\int_0^\infty f(v)dv=\frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2}\int_0^\infty v^2e^{-mv^2/2kT}dv$$

Let $a=m/2kT$ to obtain:

$$\int_0^\infty f(v)dv=\frac{4}{\sqrt{\pi}}a^{3/2}\int_0^\infty v^2e^{-av^2}dv$$

Use the given integral to obtain:

$$\int_0^\infty f(v)dv=\frac{4}{\sqrt{\pi}}a^{3/2}\left(\frac{\sqrt{\pi}}{4}a^{-3/2}\right)=\boxed{1}$$

That is, $f(v)$ is normalized.

68 •• Given that the integral $\int_0^\infty v^3 e^{-av^2}dv = \frac{1}{2a^2}$, calculate the average speed v_{av} of molecules in a gas using the Maxwell–Boltzmann distribution function.

Picture the Problem In Problem 67 we showed that $f(v)$ is normalized. Hence we can evaluate v_{av} using $\int_0^\infty vf(v)dv$.

The average speed of the molecules in the gas is given by:

$$v_{av} = \int_0^\infty vf(v)dv$$
$$= \frac{4}{\sqrt{\pi}}\left(\frac{m}{2kT}\right)^{3/2}\int_0^\infty v^3 e^{-mv^2/2kT}dv$$

Substitute $a = m/2kT$:

$$v_{av} = \frac{4}{\sqrt{\pi}}a^{3/2}\int_0^\infty v^3 e^{-av^2}dv$$

Use the given integral to obtain:

$$v_{av} = \frac{4}{\sqrt{\pi}}a^{3/2}\left(\frac{a^{-2}}{2}\right) = \frac{2}{\sqrt{\pi}}\frac{1}{\sqrt{a}}$$
$$= \boxed{\frac{2}{\sqrt{\pi}}\sqrt{\frac{2kT}{m}}}$$

69 •• The translational kinetic energies of the molecules of a gas are distributed according to the Maxwell-Boltzmann energy distribution, Equation 17-38. (*a*) Determine the most probable value of the translational kinetic energy (in terms of the temperature *T*) and compare this value to the average value. (*b*) Sketch a graph of the translational kinetic energy distribution [$f(E)$ versus E] and label the most probable energy and the average energy. (Do not worry about calibrating the vertical scale of the graph.) (*c*) Your teacher says, "Just looking at the graph $f(E)$ versus E allows you to see that the average translational kinetic energy is considerably greater than the most probable translational kinetic energy." What feature(s) of the graph support her claim?

Picture the Problem We can set the derivative of $f(E)$ with respect to E equal to zero in order to determine the most probable value of the kinetic energy of the gas molecules.

(*a*) The Maxwell-Boltzmann energy distribution function is:

$$f(E) = \left(\frac{2}{\sqrt{\pi}}\right)\left(\frac{1}{kT}\right)^{3/2}\sqrt{E}e^{-E/kT}$$

Differentiate this expression with respect to E to obtain:

$$\frac{d}{dE}f(E)=\left(\frac{2}{\sqrt{\pi}}\right)\left(\frac{1}{kT}\right)^{3/2}\left(\tfrac{1}{2}E^{-1/2}e^{-E/kT}+E^{1/2}\left(\frac{-1}{kT}\right)e^{-E/kt}\right)$$

Set this derivative equal to zero for extrema values and simplify to obtain:

$$\tfrac{1}{2}E_{\text{peak}}^{-1/2}e^{-E_{\text{peak}}/kT}+E_{\text{peak}}^{1/2}\left(\frac{-1}{kT}\right)e^{-E_{\text{peak}}/kt}=0$$

Solving for E_{peak} yields:

$$E_{\text{peak}}=\boxed{\tfrac{1}{2}kT}$$

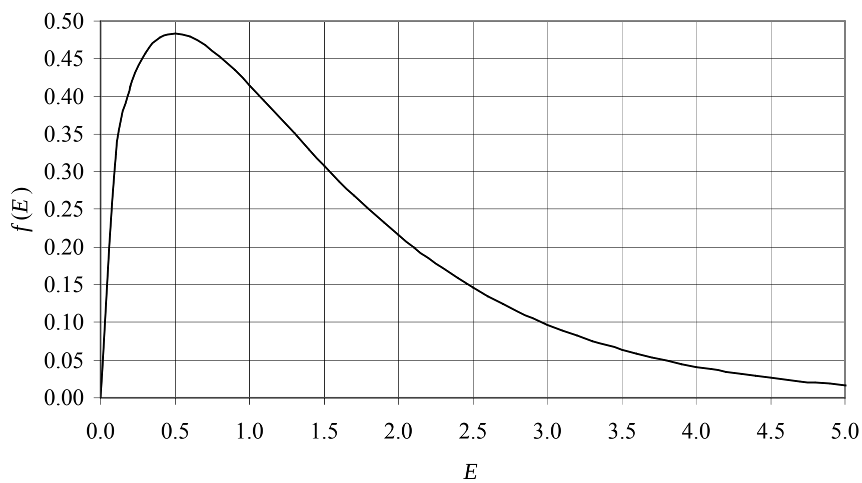
The average value of the energy of the gas molecules is given by:

$$E_{\text{av}}=\tfrac{3}{2}kT$$

Express the ratio of E_{peak} to E_{av}:

$$\frac{E_{\text{peak}}}{E_{\text{av}}}=\frac{\frac{1}{2}kT}{\frac{3}{2}kT}=\tfrac{1}{3}\Rightarrow E_{\text{peak}}=\boxed{\tfrac{1}{3}E_{\text{av}}}$$

(*b*) The following graph of the energy distribution was plotted using a spreadsheet program. Note that kT was set equal to 1 and that, as predicted by our result in (*a*), the peak value occurs for $E = 0.5$.



(*c*) The graph rises from zero to the peak much more rapidly than it falls off to the right of the peak. Because the distribution is so strongly skewed to the right of the peak, the outlying molecules with relatively high energies pull the average ($3kT/2$) far to the right of the most probable value ($kT/2$).

General Problems

70 • Find the temperature at which the rms speed of a molecule of hydrogen gas equals 343 m/s.

Picture the Problem We can use $v_{\text{rms}} = \sqrt{3RT/M}$ to relate the temperature of the H_2 molecules to their rms speed. See Appendix C for the molar mass of hydrogen.

Relate the rms speed of the hydrogen molecules to its temperature:

$$v_{\text{rms}} = \sqrt{\frac{3RT}{M_{H_2}}} \Rightarrow T = \frac{M_{H_2} v_{\text{rms}}^2}{3R}$$

Substitute numerical values and evaluate T:

$$T = \frac{(2.016\times10^{-3}\ \text{kg/mol})(343\ \text{m/s})^2}{3(8.314\ \text{J/mol}\cdot\text{K})} = \boxed{9.51\ \text{K}}$$

71 •• (*a*) If 1.0 mol of a gas in a cylindrical container occupies a volume of 10 L at a pressure of 1.0 atm, what is the temperature of the gas in kelvins? (*b*) The cylinder is fitted with a piston so that the volume of the gas (Figure 17-20) can vary. When the gas is heated at constant pressure, it expands to a volume of 20 L. What is the temperature of the gas in kelvins? (*c*) Next, the volume is fixed at 20 L, and the gas's temperature is increased to 350 K. What is the pressure of the gas now?

Picture the Problem We can use the ideal-gas law to find the initial temperature of the gas and the ideal-gas law for a fixed amount of gas to relate the volumes, pressures, and temperatures resulting from the given processes.

(*a*) Apply the ideal-gas law to express the temperature of the gas:

$$T = \frac{PV}{nR}$$

Substitute numerical values and evaluate T:

$$T = \frac{(1.0\ \text{atm})(10\ \text{L})}{(1.0\ \text{mol})\left(0.08206\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 121.9\ \text{K} = \boxed{1.2\times10^2\ \text{K}}$$

(*b*) Use the ideal-gas law for a fixed amount of gas to relate the temperatures and volumes:

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$

or, because $P_1 = P_2$,

$$\frac{V_1}{T_1} = \frac{V_2}{T_2} \Rightarrow T_2 = \frac{V_2}{V_1}T$$

Substitute numerical values and evaluate T_2:

$$T_2 = 2(121.9\,\text{K}) = 243.7\,\text{K} = \boxed{2.4\times10^2\,\text{K}}$$

(*c*) Apply the ideal-gas law to express the pressure of the gas:

$$PV = nRT \Rightarrow P = \frac{nRT}{V}$$

Substitute numerical values and evaluate P:

$$P = \frac{(1.0\,\text{mol})\left(0.08206\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(350\,\text{K})}{20\,\text{L}} = \boxed{1.4\,\text{atm}}$$

72 •• (*a*) The volume per molecule of a gas is the reciprocal of the number density (the number of molecules per unit volume). (*a*) Find the average volume per molecule for dry air at room temperature and atmospheric pressure. (*b*) Take the cube root of your answer to Part (*a*) to obtain a rough estimate of the average distance *d* between air molecules. (*c*) Find or estimate the average diameter *D* of an air molecule, and compare it to your answer to Part (*b*). (*d*) Sketch the molecules in a cube-shaped volume of air, with the edge length of the cube equal to 3*d*. Make your figure to scale and place the molecules in what you think is a typical configuration. (*e*) Use your picture to explain why the mean free path of an air molecule is much greater than the average distance between molecules.

Picture the Problem (*a*) We can use the ideal-gas law to find the average volume per molecule. (*b*) If one were to divide a container of air into little cubes, with one cube per molecule, then this distance would be the width of each cube or, equivalently, the distance from the center of one cube to the centers of the neighboring cubes. On average, we can imagine that the molecules are at the centers of their respective cubes, so this distance is also the average distance between neighboring molecules.

(*a*) The ideal-gas law relates the number of molecules *N* in a gas to the volume *V* they occupy:

$$PV = NkT \Rightarrow \frac{V}{N} = \frac{kT}{P}$$

Substitute numerical values and evaluate *V*/*N*:

$$\frac{V}{N} = \frac{(1.381\times10^{-23}\,\text{J/K})(293\,\text{K})}{101.325\,\text{kPa}} = \boxed{3.99\times10^{-26}\,\text{m}^3}$$

(*b*) Taking the cube root of *V*/*N* yields:

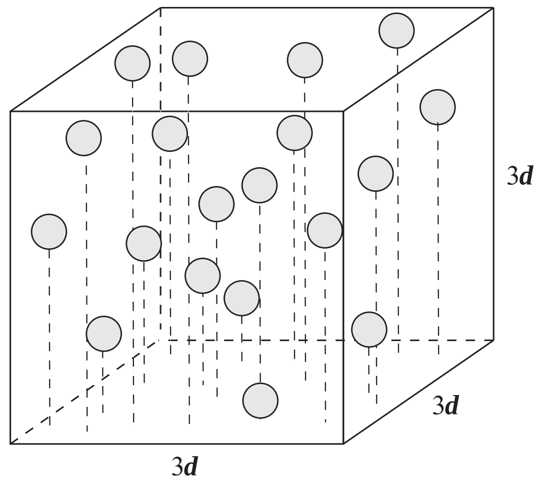
$$d = \sqrt[3]{3.99\times10^{-26}\,\text{m}^3} \approx \boxed{3.42\,\text{nm}}$$

(*c*) Example 17-10 gives the average diameter of an air molecule as:

$$D = 3.75\times10^{-10}\ \text{m} = \boxed{0.375\ \text{nm}}$$

or about 1/10 the average distance between molecules.

(*d*) A sketch of the molecules in a cube-shaped volume of air, with the edge length of the cube equal to 3*d*, follows. The random distribution of the molecules is a typical configuration.



(*e*) If a particular molecule in the diagram is moving in a random direction, its chance of colliding with a neighbor is very small because it can miss in either of the two directions perpendicular to its motion. So the mean free path, or average distance between collisions, should be many times larger than the distance to the nearest neighbor.

73 •• [SSM] The Maxwell-Boltzmann distribution applies not just to gases, but also to the molecular motions within liquids. The fact that not all molecules have the same speed helps us understand the process of evaporation. (*a*) Explain in terms of molecular motion why a drop of water becomes cooler as molecules evaporate from the drop's surface. (Evaporative cooling is an important mechanism for regulating our body temperatures, and is also used to cool buildings in hot, dry locations.) (*b*) Use the Maxwell-Boltzmann distribution to explain why even a slight increase in temperature can greatly increase the rate at which a drop of water evaporates.

Determine the Concept

(*a*) To escape from the surface of a droplet of water, molecules must have enough translational kinetic energy to overcome the attractive forces from their neighbors. Therefore the molecules that escape will be those that are moving faster, leaving the slower molecules behind. The slower molecules have less kinetic energy, so the temperature of the droplet, which is proportional to the average kinetic energy per molecule, decreases.

(*b*) As long as the temperature is not too high, the molecules that evaporate from a surface will be only those with the most extreme speeds, at the high-energy "tail" of the Maxwell-Boltzmann distribution. Within this part of the distribution, increasing the temperature only slightly can greatly increase the percentage of molecules with speeds above a certain threshold. For example, suppose that we set an initial threshold at $E = 5kT_1$, then imagine increasing the temperature by 10% so $T_2 = 1.1T_1$. At the threshold, the ratio of the new energy distribution to the old one is

$$\frac{F(T_2)}{F(T_1)} = \left(\frac{T_1}{T_2}\right)^{\frac{3}{2}} e^{\frac{-E}{kT_2}} e^{\frac{+E}{kT_1}} = (1.1)^{\frac{-3}{2}} e^{\frac{-5}{1.1}} e^5 = 1.366$$

an increase of almost 37%.

74 •• A cubic metal box that has 20-cm–long edges contains air at a pressure of 1.0 atm and a temperature of 300 K. The box is sealed so that the enclosed volume remains constant, and it is heated to a temperature of 400 K. Find the force due to the internal air pressure on each wall of the box.

Picture the Problem We can use the definition of pressure to express the net force on each wall of the box in terms of its area and the pressure differential between the inside and the outside of the box. We can apply the ideal-gas law for a fixed amount of gas to find the pressure inside the box after it has been heated.

Using the definition of pressure, express the net force on each wall of the box:

$$F = AP_{\text{inside}} \qquad (1)$$

Use the ideal-gas law for a fixed amount of gas to relate the initial and final pressures of the gas:

$$\frac{P_{\text{atm}}V_{\text{initial}}}{T_{\text{initial}}} = \frac{P_{\text{inside}}V_{\text{final}}}{T_{\text{final}}}$$

or, because $V_{\text{initial}} = V_{\text{final}}$,

$$\frac{P_{\text{atm}}}{T_{\text{initial}}} = \frac{P_{\text{inside}}}{T_{\text{final}}} \Rightarrow P_{\text{inside}} = \frac{T_{\text{final}}}{T_{\text{initial}}} P_{\text{atm}}$$

Substituting in equation (1) and simplifying yields:

$$F = \frac{T_{\text{final}}}{T_{\text{initial}}} AP_{\text{atm}}$$

Substitute numerical values and evaluate F:

$$F = (0.20\,\text{m})^2 \left(\frac{400\,\text{K}}{300\,\text{K}}\right)(101.325\,\text{kPa})$$

$$= \boxed{5.4\,\text{kN}}$$

75 •• [SSM] In attempting to create liquid hydrogen for fuel, one of the proposals is to convert plain old water (H_2O) into H_2 and O_2 gases by *electrolysis*. How many moles of each of these gases result from the electrolysis of 2.0 L of water?

Picture the Problem We can use the molar mass of water to find the number of moles in 2.0 L of water. Because there are two hydrogen atoms in each molecule of water, there must be as many hydrogen molecules in the gas formed by electrolysis as there were molecules of water and, because there is one oxygen atom in each molecule of water, there must be half as many oxygen molecules in the gas formed by electrolysis as there were molecules of water. See Appendix C for the molar masses of hydrogen and oxygen.

Express the electrolysis of water into H_2 and O_2:

$$n_{H_2O} \rightarrow n_{H_2} + \tfrac{1}{2} n_{O_2}$$

Express the number of moles in 2.0 L of water:

$$n_{H_2O} = \frac{2.0\,\text{L} \times 1000\,\frac{\text{g}}{\text{L}}}{18.02\,\text{g/mol}} = 110\,\text{mol}$$

Because there are two hydrogen atoms for each water molecule:

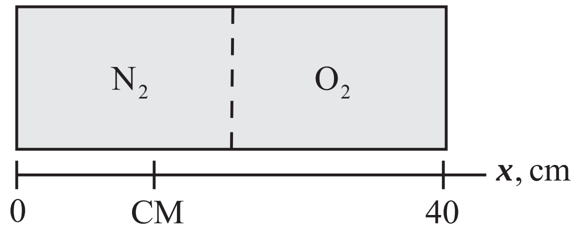
$$n_{H_2} = \boxed{110\,\text{mol}}$$

Because there is one oxygen atom for each water molecule:

$$n_{O_2} = \tfrac{1}{2} n_{H_2O} = \tfrac{1}{2}(110\,\text{mol}) = \boxed{55\,\text{mol}}$$

76 •• A hollow 40-cm-long cylinder of negligible mass rests on its side on a horizontal frictionless table. The cylinder is divided into two equal sections by a vertical non-porous membrane. One section contains nitrogen and the other contains oxygen. The pressure of the nitrogen is twice that of the oxygen. How far will the cylinder move if the membrane breaks?

Picture the Problem The diagram shows the cylinder before removal of the membrane. The distance the cylinder will move if the membrane breaks is the distance between the locations of the center of mass initially and after the membrane breaks. Because both gasses will uniformly fill the cylinder after the membrane breaks, the location of the center of mass after this break will be at the midpoint of the cylinder; that is, at 20 cm from either end of the cylinder. See Appendix C for the molar masses of oxygen and nitrogen.



Express the distance the cylinder will move in terms of the movement of the center of mass when the membrane is removed:

$$\Delta x = 20\text{ cm} - x_{\text{cm,before}} \qquad (1)$$

Apply the ideal-gas law to both collections of molecules to obtain:

$$P_{N_2}V_{N_2} = n_{N_2}kT$$

and

$$P_{O_2}V_{O_2} = n_{O_2}kT$$

Divide the first of these equations by the second to obtain:

$$\frac{P_{N_2}}{P_{O_2}} = \frac{n_{N_2}}{n_{O_2}}$$

or, because $P_{N_2} = 2P_{O_2}$,

$$\frac{2P_{O_2}}{P_{O_2}} = \frac{n_{N_2}}{n_{O_2}} \Rightarrow n_{N_2} = 2n_{O_2}$$

Express the mass of O_2 in terms of its molar mass and the number of moles of oxygen:

$$m_{O_2} = n_{O_2}M_{O_2}$$

Express the mass of N_2 in terms of its molar mass and the number of moles of nitrogen:

$$m_{N_2} = n_{O_2}M_{N_2}$$

Using the definition of center of mass, express the center of mass before the membrane is removed:

$$x_{\text{cm,before}} = \frac{\sum_i x_i m_i}{\sum_i m_i} = \frac{n_{\text{N}_2} M_{\text{N}_2} x_{\text{cm,N}_2} + n_{\text{O}_2} M_{\text{O}_2} x_{\text{cm,O}_2}}{n_{\text{N}_2} M_{\text{N}_2} + n_{\text{O}_2} M_{\text{O}_2}}$$
$$= \frac{2n_{\text{O}_2} M_{\text{N}_2} x_{\text{cm,N}_2} + n_{\text{O}_2} M_{\text{O}_2} x_{\text{cm,O}_2}}{2n_{\text{O}_2} M_{\text{N}_2} + n_{\text{O}_2} M_{\text{O}_2}}$$
$$= \frac{2M_{\text{N}_2} x_{\text{cm,N}_2} + M_{\text{O}_2} x_{\text{cm,O}_2}}{2M_{\text{N}_2} + M_{\text{O}_2}}$$

Substitute numerical values and evaluate $x_{\text{cm,before}}$:

$$x_{\text{cm, before}} = \frac{2(10\,\text{cm})(28\,\text{g}) + (30\,\text{cm})(32\,\text{g})}{2(28\,\text{g}) + 32\,\text{g}} = 17\,\text{cm}$$

Substitute numerical values in equation (1) to obtain:

$$\Delta x = 20\,\text{cm} - 17\,\text{cm} = \boxed{3\,\text{cm}}$$

Because momentum must be conserved during this process and the center of mass of the system consisting of the oxygen and nitrogen must not move. Therefore, the entire cylinder must move 3 cm to the left.

77 •• A cylinder of fixed volume contains a mixture of helium gas (He) and hydrogen gas (H_2) at a temperature T_1 and pressure P_1. If the temperature is doubled to $T_2 = 2T_1$, the pressure would also double, except for the fact that at this temperature the H_2 is essentially 100 percent dissociated into H_1. In reality, at pressure $P_2 = 2P_1$ the temperature is $T_2 = \frac{3}{2}T_1$. If the mass of the hydrogen in the cylinder is m, what is the mass of the helium in the cylinder?

Picture the Problem We can apply the ideal-gas law to the two processes to find the number of moles of hydrogen in terms of the number of moles of helium in the gas. Using the definition of molar mass, we can relate the mass of each gas to the number of moles of each gas and their molar masses. See Appendix C for the molar masses of helium gas and hydrogen gas.

Apply the ideal-gas law to the mixture when the pressure is P_1 and the temperature is T_1:

$$P_1V = \left[N_{\text{He}} + N_{\text{H}_2}\right]kT_1$$
$$= \left[n_{\text{He}}N_{\text{A}} + n_{\text{H}_2}N_{\text{A}}\right]kT_1$$
$$= \left[n_{\text{He}} + n_{\text{H}_2}\right]N_{\text{A}}kT_1$$
$$= \left[n_{\text{He}} + n_{\text{H}_2}\right]RT_1$$

Noting that when the pressure doubles, the temperature increases by a factor of 1.5 and H_2 dissociates into H_1, apply the ideal-gas law to the mixture to obtain:

$$\begin{aligned}(2P_1)V &= \left[N_{He} + 2N_{H_2}\right]k\left(\tfrac{3}{2}T_1\right)\\ &= \left[n_{He}N_A + 2n_{H_2}N_A\right]k\left(\tfrac{3}{2}T_1\right)\\ &= \left[n_{He} + 2n_{H_2}\right]N_A k\left(\tfrac{3}{2}T_1\right)\\ &= \left[n_{He} + 2n_{H_2}\right]R\left(\tfrac{3}{2}T_1\right)\end{aligned}$$

Dividing the second of these equations by the first and simplifying gives:

$$2n_{H_2} = n_{He} \qquad (1)$$

Relate m_{He} to n_{He}:

$$m_{He} = n_{He}M_{He} = n_{He}(4.003\,\text{g/mol})$$

and

$$n_{He} = \frac{m_{He}}{4.003\,\text{g/mol}}$$

Relate m to n_{H_2}:

$$m = n_{H_2}M_{H_2} = n_{H_2}(2.016\,\text{g/mol})$$

and

$$n_{H_2} = \frac{m}{2.016\,\text{g/mol}}$$

Substituting for n_{H_2} and n_{He} in equation (1) and solving for m_{He} gives:

$$\frac{2m}{2.016\,\text{g/mol}} = \frac{m_{He}}{4.003\,\text{g/mol}}$$

and

$$m_{He} \approx \boxed{4m}$$

78 •• The mean free path for O_2 molecules at a temperature of 300 K and at 1.00 atm pressure is 7.10×10^{-8} m. Use this data to estimate the size of an O_2 molecule.

Picture the Problem Because the O_2 molecule resembles 2 spheres stuck together, which in cross section look something like two circles, we can estimate the radius of the molecule from the formula for the area of a circle. We can express the area, and hence the radius, of the circle in terms of the mean free path and the number density of the molecules and use the ideal-gas law to express the number density.

Express the area of two circles of diameter d that touch each other:

$$A = 2\left(\frac{\pi d^2}{4}\right) = \frac{\pi d^2}{2} \Rightarrow d = \sqrt{\frac{2A}{\pi}} \qquad (1)$$

Relate the mean free path of the molecules to their number density and cross-sectional area:

$$\lambda = \frac{1}{n_v A} \Rightarrow A = \frac{1}{n_v \lambda}$$

Substitute for A in equation (1) to obtain:

$$d = \sqrt{\frac{2}{\pi n_v \lambda}}$$

Use the ideal-gas law to relate the number density of the O_2 molecules to their temperature and pressure:

$$PV = NkT \text{ or } n_v = \frac{N}{V} = \frac{P}{kT}$$

Substituting for n_v yields:

$$d = \sqrt{\frac{2kT}{\pi P \lambda}}$$

Substitute numerical values and evaluate d:

$$d = \sqrt{\frac{2(1.381\times10^{-23}\text{ J/K})(300\text{ K})}{\pi(101.325\text{ kPa})(7.10\times10^{-8}\text{ m})}} = \boxed{0.605\text{ nm}}$$

79 •• [SSM] Current experiments in atomic trapping and cooling can create low-density gases of rubidium and other atoms with temperatures in the nanokelvin (10^{-9} K) range. These atoms are trapped and cooled using magnetic fields and lasers in ultrahigh vacuum chambers. One method that is used to measure the temperature of a trapped gas is to turn the trap off and measure the time it takes for molecules of the gas to fall a given distance. Consider a gas of rubidium atoms at a temperature of 120 nK. Calculate how long it would take an atom traveling at the rms speed of the gas to fall a distance of 10.0 cm if (*a*) it were initially moving directly downward and (*b*) if it were initially moving directly upward. Assume that the atom doesn't collide with any others along its trajectory.

Picture the Problem Choose a coordinate system in which downward is the positive direction. We can use a constant-acceleration equation to relate the fall distance to the initial velocity of the molecule, the acceleration due to gravity, the fall time, and $v_{\text{rms}} = \sqrt{3kT/m}$ to find the initial velocity of the rubidium molecules.

(*a*) Using a constant-acceleration equation, relate the fall distance to the initial velocity of a molecule, the acceleration due to gravity, and the fall time:

$$y = v_0 t + \tfrac{1}{2} g t^2 \qquad (1)$$

Relate the rms speed of rubidium atoms to their temperature and mass:

$$v_{\text{rms}} = \sqrt{\frac{3kT}{m_{\text{Rb}}}}$$

Substitute numerical values and evaluate v_{rms}:

$$v_{\text{rms}} = \sqrt{\frac{3(1.381\times10^{-23}\ \text{J/K})(120\,\text{nK})}{(85.47\,\text{u})(1.6606\times10^{-27}\ \text{kg/u})}} = 5.918\times10^{-3}\ \text{m/s}$$

Letting $v_{\text{rms}} = v_0$, substitute in equation (1) to obtain:

$$0.100\,\text{m} = \left(5.918\times10^{-3}\ \text{m/s}\right)t + \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)t^2$$

Use the quadratic formula or your graphing calculator to solve this equation for its positive root:

$$t = 0.14218\,\text{s} = \boxed{142\ \text{ms}}$$

(*b*) If the atom is initially moving upward:

$$v_{\text{rms}} = v_0 = -5.918\times10^{-3}\ \text{m/s}$$

Substitute in equation (1) to obtain:

$$0.100\,\text{m} = \left(-5.918\times10^{-3}\ \text{m/s}\right)t + \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)t^2$$

Use the quadratic formula or your graphing calculator to solve this equation for its positive root:

$$t = \boxed{143\ \text{ms}}$$

80 ••• A cylinder is filled with 0.10 mol of an ideal gas at standard temperature and pressure, and a 1.4-kg piston seals the gas in the cylinder (Figure 17-21) with a frictionless seal. The trapped column of gas is 2.4-m high. The piston and cylinder are surrounded by air, also at standard temperature and pressure. The piston is released from rest and starts to fall. The motion of the piston ceases after the oscillations stop with the piston and the trapped air in thermal equilibrium with the surrounding air. (*a*) Find the height of the gas column. (*b*) Suppose that the piston is pushed down below its equilibrium position by a small amount and then released. Assuming that the temperature of the gas remains constant, find the frequency of vibration of the piston.

Picture the Problem (*a*) Let *A* be the cross-sectional area of the cylinder. We can use the ideal-gas law to find the height of the piston under equilibrium conditions. In (*b*), we can apply Newton's second law and the ideal-gas law for a fixed amount of gas to show that, for small displacements from its equilibrium position, the piston executes simple harmonic motion.

(*a*) Express the pressure inside the cylinder:

$$P_{\text{in}} = P_{\text{atm}} + \frac{mg}{A}$$

Apply the ideal-gas law to obtain a second expression for the pressure of the gas in the cylinder:

$$P_{\text{in}} = \frac{nRT}{V} = \frac{nRT}{hA} \qquad (1)$$

Equating these two expressions yields:

$$P_{\text{atm}} + \frac{mg}{A} = \frac{nRT}{hA}$$

Solve for *h* to obtain:

$$h = \frac{nRT}{AP_{\text{atm}} + mg} = \frac{(2.4\text{ m})AP_{\text{atm}}}{AP_{\text{atm}} + mg} = \frac{2.4\text{ m}}{1 + \dfrac{mg}{AP_{\text{atm}}}}$$

At STP, 0.10 mol of gas occupies 2.24 L. Therefore:

$$(2.4\text{ m})A = 2.24\times10^{-3}\text{ m}^3$$

and

$$A = 9.333\times10^{-4}\text{ m}^2$$

Substitute numerical values and evaluate *h*:

$$h = \frac{2.4\text{ m}}{1 + \dfrac{(1.4\text{ kg})(9.81\text{ m/s}^2)}{(9.333\times10^{-4}\text{ m}^2)(101.325\text{ kPa})}} = 2.096\text{ m} = \boxed{2.1\text{ m}}$$

(*b*) Relate the frequency of vibration of the piston to its mass and a "stiffness" constant:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}} \qquad (2)$$

where *m* is the mass of the piston and *k* is a constant of proportionality.

Letting *y* be the displacement from equilibrium, apply $\sum F_y = ma_y$ to the piston in its equilibrium position:

$$P_{\text{in}}A - mg - P_{\text{atm}}A = 0$$

For a small displacement y above equilibrium:

$$P'_{\text{in}}A - mg - P_{\text{atm}}A = ma_y$$

or

$$P'_{\text{in}}A - P_{\text{in}}A = ma_y \qquad (3)$$

Using the ideal-gas law for a fixed amount of gas and constant temperature, relate P_{in}' to P_{in}:

$$P'_{\text{in}}V' = P_{\text{in}}V$$

or

$$P'_{\text{in}}(V + Ay) = P_{\text{in}}V \Rightarrow P'_{\text{in}} = P_{\text{in}}\frac{V}{V + Ay}$$

Substituting for V and simplifying yields:

$$P'_{\text{in}}A = P_{\text{in}}A\frac{Ah}{Ah + Ay} = P_{\text{in}}A\frac{1}{1 + \frac{y}{h}}$$

Substitute in equation (3) to obtain:

$$P_{\text{in}}A\left(1 + \frac{y}{h}\right)^{-1} - P_{\text{in}}A = ma_y$$

or, for $y << h$,

$$P_{\text{in}}A\left(1 - \frac{y}{h}\right) - P_{\text{in}}A \approx ma_y \qquad (4)$$

Simplify equation (4) to obtain:

$$-P_{\text{in}}A\frac{y}{h} \approx ma_y$$

Substitute in equation (1) to obtain:

$$-\left(\frac{nRT}{Ah}\right)A\frac{y}{h} \approx ma_y \Rightarrow -\left(\frac{nRT}{h^2}\right)y \approx ma_y$$

Solving for a_y yields:

$$a_y = -\frac{nRT}{mh^2}y$$

or

$a_y = -\frac{k}{m}y$, the condition for SHM

where $\frac{k}{m} = \frac{nRT}{mh^2}$

Substitute in equation (2) to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{nRT}{mh^2}}$$

Substitute numerical values and evaluate f:

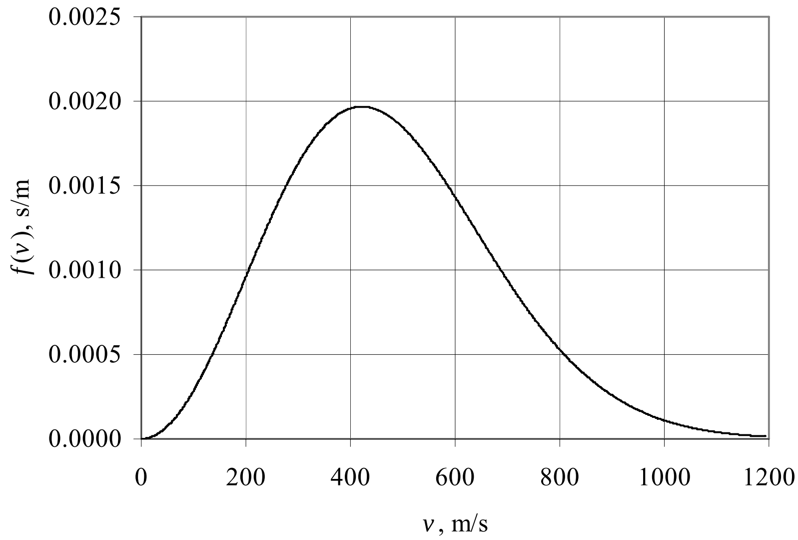
$$f = \frac{1}{2\pi}\sqrt{\frac{(0.10\,\text{mol})(8.314\,\text{J/mol}\cdot\text{K})(300\,\text{K})}{(1.4\,\text{kg})(2.096\,\text{m})^2}} = \boxed{1.0\,\text{Hz}}$$

81 ••• To solve this problem, you will use a **spreadsheet** to study the distribution of molecular speeds in a gas. Figure 17-22 should help you get started. (*a*) Enter the values for constants *R*, *M*, and *T* as shown. Then in column A, enter values of speed ranging from 0 to 1200 m/s, in increments of 1 m/s. (This spreadsheet will be long.) In cell B7, enter the formula for the Maxwell-Boltzmann fractional speed distribution. This formula contains parameters *v, R, M* and *T.* Substitute A7 for *v,* B$1 for *R,* B$2 for *M* and B$3 for *T.* Then use the FILL DOWN command to enter the formula in the cells below B7. Create a graph of *f*(*v*) versus *v* using the data in columns A and B. (*b*) Explore how the graph changes as you increase and decrease the temperature, and describe the results. (*c*) Add a third column in which each cell contains the cumulative sum of all *f*(*v*) values, multiplied by the interval size *dv* (which equals 1), in the rows above and including the row in question. What is the physical interpretation of the numbers in this column? (*d*) For nitrogen gas at 300 K, what percentage of the molecules has speeds less than 200 m/s? (*e*) For nitrogen gas at 300 K, what percentage of the molecules has speeds greater than 700 m/s?

(*a*) The first few rows of the spreadsheet are shown below. Note that the column for Part (*c*) is included.

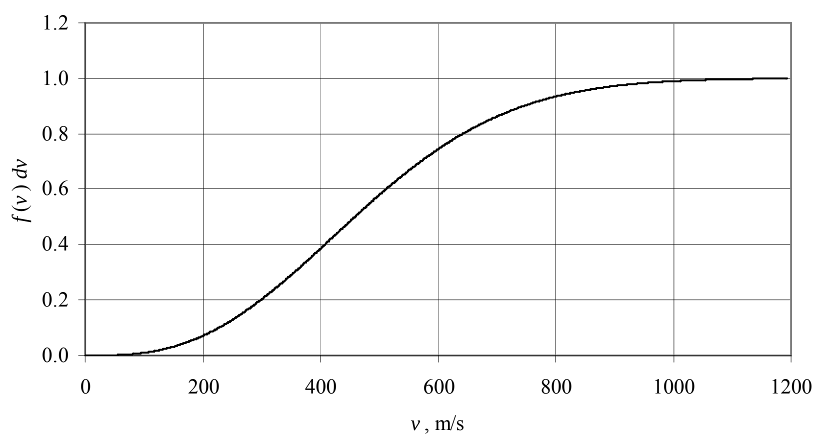
	A	B	C
1	*R*=	8.31	J/mol-K
2	*M*=	0.028	kg/mol
3	*T*=	300	K
4			
5	*v*	*f*(v)	sum *f*(*v*)*dv*
6	(m/s)	(s/m)	(unitless)
7	0	0.00E+00	0.00E+00
8	1	3.00E−08	3.00E−08
9	2	1.20E−07	1.50E−07
10	3	2.70E−07	4.20E−07
11	4	4.80E−07	9.01E−07
12	5	7.51E−07	1.65E−06

A graph of $f(v)$ for nitrogen at 300 K follows:



(*b*) As the temperature is increased the horizontal position of the peak moves to the right in proportion to the square root of the temperature, while the height of the peak drops by the same factor, preserving the total area under the graph (which must be 1.0).

(*c*) Each number in column C of the spreadsheet (shown in (*a*)) is approximately equal to the integral of $f(v)$ from zero up to the corresponding v value. This integral represents the probability of a molecule having a speed less than or equal to this value of v.



(*d*) Looking in cell C207, we find that the probability (at 300 K) of a nitrogen molecule having a speed less than 200 m/s is $\boxed{0.0706}$, or about 7%. Note that this value is consistent with the graph of $f(v)$ shown immediately above.

(*e*) Looking in cell C707, we find that the probability of a nitrogen molecule having a speed less than 700 m/s is approximately 0.862, so the probability of it having a speed greater than this would be 1 – 0.862 or $\boxed{0.138}$, or a little under 14%.

Chapter 18
Heat and the First Law of Thermodynamics

Conceptual Problems

1 • Object A has a mass that is twice the mass of object B and object A has a specific heat that is twice the specific heat of object B. If equal amounts of heat are transferred to these objects, how do the subsequent changes in their temperatures compare? (*a*) $\Delta T_A = 4\Delta T_B$, (*b*) $\Delta T_A = 2\Delta T_B$, (*c*) $\Delta T_A = \Delta T_B$, (*d*) $\Delta T_A = \frac{1}{2}\Delta T_B$, (*e*) $\Delta T_A = \frac{1}{4}\Delta T_B$

Picture the Problem We can use the relationship $Q = mc\Delta T$ to relate the temperature changes of objects A and B to their masses, specific heats, and the amount of heat supplied to each.

Express the change in temperature of object A in terms of its mass, specific heat, and the amount of heat supplied to it:

$$\Delta T_A = \frac{Q}{m_A c_A}$$

Express the change in temperature of object B in terms of its mass, specific heat, and the amount of heat supplied to it:

$$\Delta T_B = \frac{Q}{m_B c_B}$$

Divide the second of these equations by the first to obtain:

$$\frac{\Delta T_B}{\Delta T_A} = \frac{m_A c_A}{m_B c_B}$$

Substitute and simplify to obtain:

$$\frac{\Delta T_B}{\Delta T_A} = \frac{(2m_B)(2c_B)}{m_B c_B} = 4 \Rightarrow \Delta T_A = \tfrac{1}{4}\Delta T_B$$

and $\boxed{(e)}$ is correct.

2 • Object A has a mass that is twice the mass of object B. The temperature change of object A is equal to the temperature change of object B when the objects absorb equal amounts of heat. It follows that their specific heats are related by (*a*) $c_A = 2c_B$, (*b*) $2c_A = c_B$, (*c*) $c_A = c_B$, (*d*) none of the above

Picture the Problem We can use the relationship $Q = mc\Delta T$ to relate the temperature changes of objects A and B to their masses, specific heats, and the amount of heat supplied to each.

Relate the temperature change of object A to its specific heat and mass:

$$\Delta T_{\text{A}} = \frac{Q}{m_{\text{A}}c_{\text{A}}}$$

Relate the temperature change of object B to its specific heat and mass:

$$\Delta T_{\text{B}} = \frac{Q}{m_{\text{B}}c_{\text{B}}}$$

Equate the temperature changes and simplify to obtain:

$$\frac{1}{m_{\text{B}}c_{\text{B}}} = \frac{1}{m_{\text{A}}c_{\text{A}}}$$

Solve for c_{A}:

$$c_{\text{A}} = \frac{m_{\text{B}}}{m_{\text{A}}}c_{\text{B}} = \frac{m_{\text{B}}}{2m_{\text{B}}}c_{\text{B}} = \tfrac{1}{2}c_{\text{B}}$$

and $\boxed{(b)}$ is correct.

3 • [SSM] The specific heat of aluminum is more than twice the specific heat of copper. A block of copper and a block of aluminum have the same mass and temperature (20ºC). The blocks are simultaneously dropped into a single calorimeter containing water at 40ºC. Which statement is true when thermal equilibrium is reached? (*a*) The aluminum block is at a higher temperature than the copper block. (*b*) The aluminum block has absorbed less energy than the copper block. (*c*) The aluminum block has absorbed more energy than the copper block. (*d*) Both (*a*) and (*c*) are correct statements.

Picture the Problem We can use the relationship $Q = mc\Delta T$ to relate the amount of energy absorbed by the aluminum and copper blocks to their masses, specific heats, and temperature changes.

Express the energy absorbed by the aluminum block:

$$Q_{\text{Al}} = m_{\text{Al}}c_{\text{Al}}\Delta T$$

Express the energy absorbed by the copper block:

$$Q_{\text{Cu}} = m_{\text{Cu}}c_{\text{Cu}}\Delta T$$

Divide the second of these equations by the first to obtain:

$$\frac{Q_{\text{Cu}}}{Q_{\text{Al}}} = \frac{m_{\text{Cu}}c_{\text{Cu}}\Delta T}{m_{\text{Al}}c_{\text{Al}}\Delta T}$$

Because the block's masses are the same and they experience the same change in temperature:

$$\frac{Q_{\text{Cu}}}{Q_{\text{Al}}} = \frac{c_{\text{Cu}}}{c_{\text{Al}}} < 1$$

or

$Q_{\text{Cu}} < Q_{\text{Al}}$ and $\boxed{(c)}$ is correct.

4 • A block of copper is in a pot of boiling water and has a temperature of 100°C. The block is removed from the boiling water and immediately placed in an insulated container filled with a quantity of water that has a temperature of 20°C and has the same mass as the block of copper. (The heat capacity of the insulated container is negligible.) The final temperature will be closest to (*a*) 40°C, (*b*) 60°C, (*c*) 80°C.

Determine the Concept We can use the relationship $Q = mc\Delta T$ to relate the temperature changes of the block of copper and the boiling water to their masses, specific heats, and the amount of heat supplied to or absorbed by each.

Relate the heat supplied by the block of copper to its specific heat, mass, and temperature change as it cools to its equilibrium temperature:

$$\Delta Q_{Cu} = m_{Cu}c_{Cu}\Delta T_{Cu} = m_{Cu}c_{Cu}\left(T_{equil} - 100°C\right)$$

Relate the heat absorbed by the water to its specific heat, mass, and temperature change as it warms to its equilibrium temperature:

$$\Delta Q_{H_2O} = m_{H_2O}c_{H_2O}\Delta T_{H_2O} = m_{H_2O}c_{H_2O}\left(T_{equil} - 20°C\right)$$

Because thermal energy is conserved in this mixing process:

$$\Delta Q = \Delta Q_{Cu} + \Delta Q_{H_2O} = 0$$

or

$$m_{Cu}c_{Cu}\left(T_{equil} - 100°C\right) + m_{H_2O}c_{H_2O}\left(T_{equil} - 20°C\right) = 0$$

Because the mass of the water is equal to the mass of the block of copper:

$$c_{Cu}\left(T_{equil} - 100°C\right) + c_{H_2O}\left(T_{equil} - 20°C\right) = 0$$

Solving for T_{equil} yields:

$$T_{equil} = \frac{(100°C)c_{Cu} + (20°C)c_{H_2O}}{c_{Cu} + c_{H_2O}}$$

Substitute numerical values (See Table 18-1 for the specific heats of copper and water.)and evaluate T_{equil}:

$$T_{equil} = \frac{(100°C)\left(0.386\,\frac{kJ}{kg\cdot C°}\right) + (20°C)\left(4.18\,\frac{kJ}{kg\cdot C°}\right)}{0.386\,\frac{kJ}{kg\cdot C°} + 4.18\,\frac{kJ}{kg\cdot C°}} \approx 27°C \Rightarrow \boxed{(a)} \text{ is correct.}$$

5 • You pour both a certain amount of water at 100°C and an equal amount of water at 20°C into an insulated container. The final temperature of the mixture will be (a) 60°C, (b) less than 60°C, (c) greater than 60°C.

Determine the Concept We can use the relationship $Q = mc\Delta T$ to relate the temperature changes of the room-temperature water and the boiling water to their masses, specific heats, and the amount of heat supplied to or absorbed by each.

Because thermal energy is conserved in this mixing process:

$$\Delta Q = \Delta Q_{\text{hot H}_2\text{O}} + \Delta Q_{\text{H}_2\text{O}} = 0$$

or

$$m_{\text{hot H}_2\text{O}} c_{\text{hot H}_2\text{O}} \left(T_{\text{equil}} - 100°\text{C}\right) + m_{\text{H}_2\text{O}} c_{\text{H}_2\text{O}} \left(T_{\text{equil}} - 20°\text{C}\right) = 0$$

Because the mass of the boiling water is equal to the mass of the water that is initially at 20°C and the specific heat of water is independent of its temperature:

$$T_{\text{equil}} - 100°\text{C} + T_{\text{equil}} - 20°\text{C} = 0$$

Solving for T_{equil} yields: $T_{\text{equil}} = 60°\text{C}$

and $\boxed{(a)}$ is correct.

6 • You pour some water at 100°C and some ice cubes at 0°C into an insulated container. The final temperature of the mixture will be (*a*) 50°C, (*b*) less than 50°C but larger than 0°C, (*c*) 0°C, (*d*) You cannot tell the final temperature from the data given.

Determine the Concept We would need to know the mass of the boiling water and the mass of the melting ice in order to determine the final temperature of the mixture. $\boxed{(d)}$ is correct.

7 • You pour water at 100°C and some ice cubes at 0°C into an insulated container. When thermal equilibrium is reached, you notice some ice remains and floats in liquid water. The final temperature of the mixture is (*a*) above 0°C, (*b*) less than 0°C, (*c*) 0°C, (*d*) You cannot tell the final temperature from the data given

Determine the Concept Because some ice remains when thermal equilibrium is reached, the equilibrium temperature must be the temperature of the ice cubes at their melting point. $\boxed{(c)}$ is correct.

8 • Joule's experiment establishing the mechanical equivalence of heat involved the conversion of mechanical energy into internal energy. Give some everyday examples in which some of the internal energy of a system is converted into mechanical energy.

Determine the Concept One example from everyday life is that of a hot gas that expands and does work–as in the piston of an engine. Another example is the gas escaping from a can of spray paint. As it escapes, it moves air molecules and, in the process, does work against atmospheric pressure.

9 • Can a gas absorb heat while its internal energy does not change? If so, give an example. If not, explain why not.

Determine the Concept Yes. $\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$. If the gas does work at the same rate that it absorbs heat, its internal energy will remain constant.

10 • The equation $\Delta E_{\text{int}} = Q + W$ is the formal statement of the first law of thermodynamics. In this equation, the quantities Q and W, respectively, represent (*a*) the heat absorbed by the system and the work done by the system, (*b*) the heat absorbed by the system and the work done on the system, (*c*) the heat released by the system and the work done by the system, (*d*) the heat released by the system and the work done on the system.

Determine the Concept According to the first law of thermodynamics, the change in the internal energy of the system is equal to the heat that enters the system plus the work done on the system. $\boxed{(b)}$ is correct.

11 • **[SSM]** A real gas cools during a free expansion, while an ideal gas does not cool during a free expansion. Explain the reason for this difference.

Determine the Concept Particles that attract each other have more potential energy the farther apart they are. In a real gas the molecules exert weak attractive forces on each other. These forces increase the internal potential energy during an expansion. An increase in potential energy means a decrease in kinetic energy, and a decrease in kinetic energy means a decrease in translational kinetic energy. Thus, there is a decrease in temperature.

12 • An ideal gas that has a pressure of 1.0 atm and a temperature of 300 K is confined to half of an insulated container by a thin partition. The other half of the container is a vacuum. The partition is punctured and equilibrium is quickly reestablished. Which of the following is correct? (*a*) The gas pressure is 0.50 atm and the temperature of the gas is 150 K. (*b*) The gas pressure is 1.0 atm and the temperature of the gas is 150 K. (*c*) The gas pressure is 0.50 atm and the temperature of the gas is 300 K. (*d*) None of the above.

Determine the Concept Because the container is insulated, no energy is exchanged with the surroundings during the expansion of the gas. Neither is any work done on or by the gas during this process. Hence, the internal energy of the gas does not change and we can conclude that the equilibrium temperature will be the same as the initial temperature. Applying the ideal-gas law for a fixed amount of gas we see that the pressure at equilibrium must be half an atmosphere. $\boxed{(c)}$ is correct.

13 • A gas consists of ions that repel each other. The gas undergoes a free expansion in which no heat is absorbed or released and no work is done. Does the temperature of the gas increase, decrease, or remain the same? Explain your answer.

Determine the Concept Particles that repel each other have more potential energy the closer together they are. The repulsive forces decrease the internal potential energy during an expansion. A decrease in potential energy means an increase in kinetic energy, and an increase in kinetic energy means an increase in translational kinetic energy. Thus, there is an increase in temperature.

14 • Two gas-filled rubber balloons that have equal volumes are located at the bottom of a dark, cold lake. The temperature of the water decreases with increasing depth. One balloon rises rapidly and expands adiabatically as it rises. The other balloon rises more slowly and expands isothermally. The pressure in each balloon remains equal to the pressure in the water just next to the balloon. Which balloon has the larger volume when it reaches the surface of the lake? Explain your answer.

Determine the Concept The balloon that expands isothermally is larger when it reaches the surface. The balloon that expands adiabatically will be at a lower temperature than the one that expands isothermally. Because each balloon has the same number of gas molecules and are at the same pressure, the one with the higher temperature will be bigger. An analytical argument that leads to the same conclusion is shown below.

Letting the subscript ″a″ denote the adiabatic process and the subscript ″i″ denote the isothermal process, express the equation of state for the adiabatic balloon:

$$P_0V_0^\gamma = P_\mathrm{f}V_\mathrm{f,a}^\gamma \Rightarrow V_\mathrm{f,a} = V_0\left(\frac{P_0}{P_\mathrm{f}}\right)^{1/\gamma}$$

For the isothermal balloon:

$$P_0V_0 = P_\mathrm{f}V_\mathrm{f,i} \Rightarrow V_\mathrm{f,i} = V_0\left(\frac{P_0}{P_\mathrm{f}}\right)$$

Divide the second of these equations by the first and simplify to obtain:

$$\frac{V_{\text{f,i}}}{V_{\text{f,a}}}=\frac{V_0\left(\dfrac{P_0}{P_\text{f}}\right)}{V_0\left(\dfrac{P_0}{P_\text{f}}\right)^{1/\gamma}}=\left(\frac{P_0}{P_\text{f}}\right)^{1-1/\lambda}$$

Because $P_0/P_\text{f} > 1$ and $\gamma > 1$:

$$\boxed{V_{\text{f,i}} > V_{\text{f,a}}}$$

15 • A gas changes its state quasi-statically from A to C along the paths shown in Figure 18-21. The work done by the gas is (*a*) greatest for path A→B→C, (*b*) least for path A→C, (*c*) greatest for path A→D→C, (*d*) The same for all three paths.

Determine the Concept The work done along each of these paths equals the area under its curve. The area is greatest for the path A→B→C and least for the path A→D→C. $\boxed{(a)}$ is correct.

16 • When an ideal gas undergoes an adiabatic process, (*a*) no work is done by the system, (*b*) no heat is transferred to the system, (*c*) the internal energy of the system remains constant, (*d*) the amount of heat transferred into the system equals the amount of work done by the system.

Determine the Concept An adiabatic process is, by definition, one for which no heat enters or leaves the system. $\boxed{(b)}$ is correct.

17 • True or false:

(*a*) When a system can go from state 1 to state 2 by several different processes, the amount of heat absorbed by the system will be the same for all processes.
(*b*) When a system can go from state 1 to state 2 by several different processes, the work done on the system will be the same for all processes.
(*c*) When a system can go from state 1 to state 2 by several different processes, the change in the internal energy of the system will be the same for all processes.
(*d*) The internal energy of a given amount of an ideal gas depends only on its absolute temperature.
(*e*) A quasi-static process is one in which the system is never far from being in equilibrium.
(*f*) For any substance that expands when heated, its C_p is greater than its C_v.

(*a*) False. The amount the internal energy of the system changes along any path depends only on the temperatures at state 1 and state 2, but because $\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$, Q_{in} depends on W_{on}, which, in turn, depends on the path taken from state 1 to state 2.

(*b*) False. The work done on the system depends on the path taken from state 1 to state 2.

(*c*) True. The amount the internal energy of the system changes along any path depends only on the temperatures at state 1 and state 2.

(*d*) True. For an ideal gas, $E_{\text{int}} = \frac{3}{2}nRT$. For a ″given amount″ of an ideal gas, n is constant.

(*e*) True. This is the definition of a quasi-static process.

(*f*) True. All materials have values for C_{p} and C_{v} for which it is true that C_{p} is greater than C_{v}. For liquids and solids we generally ignore the very small difference between C_{p} and C_{v} .

18 • The volume of a sample of gas remains constant while its pressure increases. (*a*) The internal energy of the system is unchanged. (*b*) The system does work. (*c*) The system absorbs no heat. (*d*) The change in internal energy must equal the heat absorbed by the system. (e) None of the above.

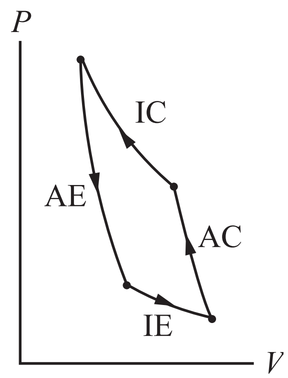
Determine the Concept For a constant-volume process, no work is done on or by the gas. Applying the first law of thermodynamics, we obtain $Q_{\text{in}} = \Delta E_{\text{int}}$. Because the temperature must change during such a process, we can conclude that $\Delta E_{\text{int}} \neq 0$ and hence $Q_{\text{in}} \neq 0$. $\boxed{(d)}$ is correct.

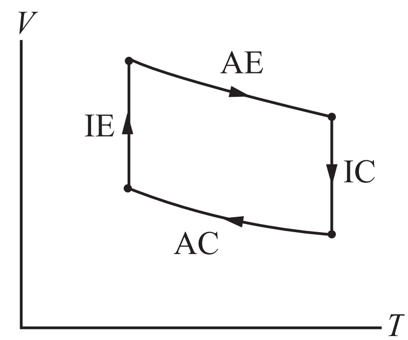
19 • When an ideal gas undergoes an isothermal process, (*a*) no work is done by the system, (*b*) no heat is absorbed by the system, (*c*) the heat absorbed by the system equals the change in the system's internal energy, (*d*) the heat absorbed by the system equals the work done by the system.

Determine the Concept Because the temperature does not change during an isothermal process, the change in the internal energy of the gas is zero. Applying the first law of thermodynamics, we obtain $Q_{\text{in}} = -W_{\text{on}} = W_{\text{by the system}}$. Hence $\boxed{(d)}$ is correct.

20 •• Consider the following series of sequential quasi-static processes that a system undergoes: (1) an adiabatic expansion, (2) an isothermal expansion, (3) an adiabatic compression and (4) an isothermal compression which brings the system back to its original state. Sketch the series of processes on a *PV* diagram, and then sketch the series of processes on a *VT* diagram (in which volume is plotted as function of temperature).

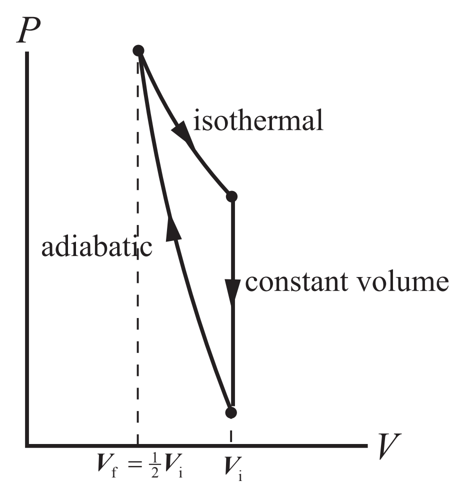
Determine the Concept In the graphs shown below, ″I″ denotes an isothermal process, ″A″ denotes an adiabatic process, ″E″ denotes an expansion, and ″C″ denotes a compression.





21 •• **[SSM]** An ideal gas in a cylinder is at pressure *P* and volume *V*. During a quasi-static adiabatic process, the gas is compressed until its volume has decreased to *V*/2. Then, in a quasi-static isothermal process, the gas is allowed to expand until its volume again has a value of *V*. What kind of process will return the system to its original state? Sketch the cycle on a graph.

Determine the Concept During a reversible adiabatic process, PV^{γ} is constant, where $\gamma < 1$ and during an isothermal processes PV is constant. Thus, the pressure rise during the compression is greater than the pressure drop during the expansion. The final process could be a constant volume process during which heat is absorbed from the system. A constant-volume cooling will decrease the pressure and return the gas to its original state.



22 •• Metal A is denser than metal B. Which would you expect to have a higher heat capacity per unit mass, metal A or metal B? Why?

Determine the Concept We can use the definition of heat capacity, the Dulong-Petit law, and the relationship between the mass of a substance and its molar mass to predict whether metal A or metal B has a higher heat capacity per unit mass.

The specific heat of metal A is given by:

$$c_A = \frac{c'}{M_A}$$

From the Dulong-Petit law, the molar heat capacity of most metals is approximately:

$$c' = 3R$$

Substituting for c' yields:

$$c_A = \frac{3R}{M_A}$$

Similarly, the specific heat of metal B is given by:

$$c_B = \frac{3R}{M_B}$$

Dividing c_A by c_B and simplifying yields:

$$\frac{c_A}{c_B} = \frac{\frac{3R}{M_A}}{\frac{3R}{M_B}} = \frac{M_B}{M_A} \Rightarrow c_A = \frac{M_B}{M_A} c_B$$

Because metal A is denser than metal B:

$$\boxed{c_A > c_B}$$

23 •• An ideal gas undergoes a process during which $P\sqrt{V} = \text{constant}$ and the volume of the gas decreases. Does its temperature increase, decrease, or remain the same during this process? Explain.

Picture the Problem We can use the given dependence of the pressure on the volume and the ideal-gas law to show that if the volume decreases, so does the temperature.

We're given that:

$$P\sqrt{V} = \text{constant}$$

Because the gas is an ideal gas:

$$PV = \left(P\sqrt{V}\right)\sqrt{V} = \text{constant} \times \sqrt{V}$$
$$= nRT$$

Solving for T yields:

$$T = \frac{(\text{constant})\sqrt{V}}{nR} \propto \sqrt{V}$$

Because T varies with the square root of V, if the volume decreases, the temperature decreases.

Estimation and Approximation

24 • During the early stages of designing a modern electric generating plant, you are in charge of the team of environmental engineers. The new plant is to be located on the ocean and will use ocean water for cooling. The plant will produce electrical power at the rate of 1.00 GW. Because the plant will have an efficiency of one-third (typical of most modern plants), heat will be released to the cooling water at the rate of 2.00 GW. If environmental codes require that only water with a temperature increase of 15°F or less can be returned to the ocean, estimate the flow rate (in kg/s) of cooling water through the plant.

Picture the Problem The rate at which thermal energy is delivered to the ocean by the power plant is given by $P = \Delta Q/\Delta t$ where $Q = mc\Delta T$

Express the rate at which thermal energy is delivered to the ocean:

$$P = \frac{\Delta Q}{\Delta t} = \frac{\Delta}{\Delta t}(mc\Delta T) = \frac{\Delta m}{\Delta t}c\Delta T$$

Our interest is in the flow rate of the cooling water. Solving for $\Delta m/\Delta t$ yields:

$$\frac{\Delta m}{\Delta t} = \frac{P}{c\Delta T}$$

Substitute numerical values and evaluate $\Delta m/\Delta t$:

$$\frac{\Delta m}{\Delta t} = \frac{2.00\times10^{9}\ \text{J/s}}{\left(4.184\,\frac{\text{kJ}}{\text{kg}\cdot\text{C°}}\right)\left(15\ \text{F°}\times\frac{5\ \text{C°}}{9\ \text{F°}}\right)} = \boxed{5.7\times10^{4}\ \text{kg/s}}$$

25 •• **[SSM]** A ″typical″ microwave oven has a power consumption of about 1200 W. Estimate how long it should take to boil a cup of water in the microwave assuming that 50% of the electrical power consumption goes into heating the water. How does this estimate correspond to everyday experience?

Picture the Problem Assume that the water is initially at 30°C and that the cup contains 200 g of water. We can use the definition of power to express the required time to bring the water to a boil in terms of its mass, heat capacity, change in temperature, and the rate at which energy is supplied to the water by the microwave oven.

Use the definition of power to relate the energy needed to warm the water to the elapsed time:

$$P = \frac{\Delta W}{\Delta t} = \frac{mc\Delta T}{\Delta t} \Rightarrow \Delta t = \frac{mc\Delta T}{P}$$

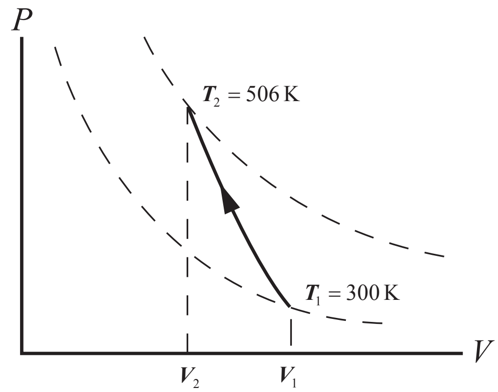
Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{(0.200\,\text{kg})\left(4.184\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(100°\text{C} - 30°\text{C})}{600\,\text{W}} = 97.63\,\text{s} \approx \boxed{1.6\,\text{min}},$$

an elapsed time that seems to be consistent with experience.

26 •• A demonstration of the heating of a gas under adiabatic compression involves putting a small strip of paper into a large glass test tube, which is then sealed off with a piston. If the piston compresses the trapped air very rapidly, the paper will catch fire. Assuming that the burning point of paper is 451ºF, estimate the factor by which the volume of the air trapped by the piston must be reduced for this demonstration to work.

Picture the Problem The adiabatic compression from an initial volume V_1 to a final volume V_2 between the isotherms at temperatures T_1 and T_2 is shown below. We'll assume a room temperature of 300 K and apply the equation for a quasi-static adiabatic compression to 451ºF (506 K) with $\gamma_{\text{air}} = 1.4$ to solve for the ratio of the initial to the final volume of the air.



Express $TV^{\gamma-1} = \text{constant}$ in terms of the initial and final values of T and V:

$$T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1} \Rightarrow \frac{V_1}{V_2} = \left(\frac{T_2}{T_1}\right)^{\frac{1}{\gamma-1}}$$

Substitute numerical values and evaluate V_1/V_2:

$$\frac{V_1}{V_2} = \left(\frac{506\,\text{K}}{300\,\text{K}}\right)^{\frac{1}{1.4-1}} = \boxed{3.69}$$

27 •• A small change in the volume of a liquid occurs when heating the liquid at constant pressure. Use the following data to estimate the fractional contribution this change makes to the heat capacity of water between 4.00ºC and 100ºC. The density of water at 4.00ºC and 1.00 atm pressure is 1.000 g/cm^3. The density of liquid water at 100ºC and 1.00 atm pressure is 0.9584 g/cm^3.

Picture the Problem The heat capacity C_p of a sample of water is equal to the mass m of the sample times the specific heat capacity c_p of water, where c_p = 4186 J/kg·K. When the sample is heated, its temperature and its volume increases. The increase in temperature reflects the increase in the internal energy of the sample, and the increase in volume reflects the amount of work W_{on} done by the sample on its surroundings. That is, $W_{on} = P\Delta V$, where P is the pressure and ΔV is the change in volume of the sample. We are looking for the ratio of the work done by the sample to the heat absorbed by the sample.

The heat that enters the water during the constant pressure process is given by:

$$Q_{in} = mc_p\Delta T$$

The work that is done by the sample during this process is given by:

$$W_{by} = P\Delta V = P(V_{100°C} - V_{4.00°C})$$

The volumes of the sample at these temperatures is related to its densities at these temperatures:

$$W_{by} = P\left(\frac{m}{\rho_{100°C}} - \frac{m}{\rho_{4.00°C}}\right) = Pm\left(\frac{1}{\rho_{100°C}} - \frac{1}{\rho_{4.00°C}}\right)$$

where m is the mass of the sample.

Taking the ratio of W_{by} to Q_{in} yields:

$$\frac{W_{by}}{Q_{in}} = \frac{Pm}{mc_p\Delta T}\left(\frac{1}{\rho_{100°C}} - \frac{1}{\rho_{4.00°C}}\right) = \frac{P}{c_p\Delta T}\left(\frac{1}{\rho_{100°C}} - \frac{1}{\rho_{4.00°C}}\right)$$

Substitute numerical values and evaluate W_{by}/Q_{in}:

$$\frac{W_{by}}{Q_{in}} = \frac{101.325\times 10^3\ \text{Pa}}{\left(4186\ \frac{\text{J}}{\text{kg}\cdot\text{K}}\right)(96\ \text{K})}\left(\frac{1}{954.3\ \frac{\text{kg}}{\text{m}^3}} - \frac{1}{1000\frac{\text{kg}}{\text{m}^3}}\right) = \boxed{1.2\times 10^{-3}\%}$$

Heat Capacity, Specific Heat, Latent Heat

28 • You designed a solar home that contains 1.00×10^5 kg of concrete (specific heat = 1.00 kJ/kg·K). How much heat is released by the concrete at night when it cools from 25.0ºC to 20.0ºC?

Picture the Problem We can use the relationship $Q = mc\Delta T$ to calculate the amount of heat given off by the concrete as it cools from 25.0°C to 20.0°C.

Relate the heat given off by the concrete to its mass, specific heat, and change in temperature:

$$Q = mc\Delta T$$

Substitute numerical values and evaluate Q:

$$Q = \left(1.00\times10^{5}\text{ kg}\right)\left(1.00\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\left(25.0°\text{C} - 20.0°\text{C}\right) = \boxed{500\,\text{kJ}}$$

29 • **[SSM]** How much heat must be absorbed by 60.0 g of ice at –10.0ºC to transform it into 60.0 g of water at 40.0ºC?

Picture the Problem We can find the amount of heat that must be absorbed by adding the heat required to warm the ice from −10.0°C to 0°C, the heat required to melt the ice, and the heat required to warm the water formed from the ice to 40.0°C.

Express the total heat required:

$$Q = Q_{\text{warm ice}} + Q_{\text{melt ice}} + Q_{\text{warm water}}$$

Substitute for each term to obtain:

$$\begin{aligned} Q &= mc_{\text{ice}}\Delta T_{\text{ice}} + mL_{\text{f}} + mc_{\text{water}}\Delta T_{\text{water}} \\ &= m\left(c_{\text{ice}}\Delta T_{\text{ice}} + L_{\text{f}} + c_{\text{water}}\Delta T_{\text{water}}\right) \end{aligned}$$

Substitute numerical values (See Tables 18-1 and 18-2) and evaluate Q:

$$\begin{aligned} Q &= \left(0.0600\,\text{kg}\right)\left[\left(2.05\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\left(0°\text{C} - \left(-10.0°\text{C}\right)\right) + 333.5\frac{\text{kJ}}{\text{kg}}\right. \\ &\qquad \left. + \left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\left(40.0°\text{C} - 0°\text{C}\right)\right] \\ &= \boxed{31.3\,\text{kJ}} \end{aligned}$$

30 •• How much heat must be released by 0.100 kg of steam at 150ºC to transform it into 0.100 kg of ice at 0ºC?

Picture the Problem We can find the amount of heat that must be removed by adding the heat that must be removed to cool the steam from 150°C to 100°C, the heat that must be removed to condense the steam to water, the heat that must be removed to cool the water from 100°C to 0°C, and the heat that must be removed to freeze the water.

Express the total heat that must be removed:

$$Q = Q_{\text{cool steam}} + Q_{\text{condense steam}} + Q_{\text{cool water}} + Q_{\text{freeze water}}$$

Substitute for each term and simplify to obtain:

$$\begin{aligned} Q &= mc_{\text{steam}}\Delta T_{\text{steam}} + mL_{\text{v}} + mc_{\text{water}}\Delta T_{\text{water}} + mL_{\text{f}} \\ &= m\left(c_{\text{steam}}\Delta T_{\text{steam}} + L_{\text{v}} + c_{\text{water}}\Delta T_{\text{water}} + L_{\text{f}}\right) \end{aligned}$$

Substitute numerical values (See Tables 18-1 and 18-2) and evaluate Q:

$$\begin{aligned} Q = (0.100\,\text{kg})\Bigg[&\left(2.02\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(150°\text{C} - 100°\text{C}) + 2.26\frac{\text{MJ}}{\text{kg}} \\ &+ \left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(100°\text{C} - 0°\text{C}) + 333.5\frac{\text{kJ}}{\text{kg}}\Bigg] \\ = {}&\boxed{311\,\text{kJ}} \end{aligned}$$

31 •• A 50.0-g piece of aluminum at 20ºC is cooled to –196ºC by placing it in a large container of liquid nitrogen at that temperature. How much nitrogen is vaporized? (Assume that the specific heat of aluminum is constant over this temperature range.)

Picture the Problem We can find the amount of nitrogen vaporized by equating the heat gained by the liquid nitrogen and the heat lost by the piece of aluminum.

Express the heat gained by the liquid nitrogen as it cools the piece of aluminum:

$$Q_{\text{N}} = m_{\text{N}}L_{\text{v,N}}$$

Express the heat lost by the piece of aluminum as it cools:

$$Q_{\text{Al}} = m_{\text{Al}}c_{\text{Al}}\Delta T_{\text{Al}}$$

Equate these two expressions and solve for m_{N}:

$$m_{\text{N}}L_{\text{v,N}} = m_{\text{Al}}c_{\text{Al}}\Delta T_{\text{Al}}$$

and

$$m_{\text{N}} = \frac{m_{\text{Al}}c_{\text{Al}}\Delta T_{\text{Al}}}{L_{\text{v,N}}}$$

Substitute numerical values (see Table 18-1 for the specific heat of aluminum) and evaluate m_N:

$$m_N = \frac{(0.0500\,\text{kg})\left(0.900\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(20°\text{C} - (-196°\text{C}))}{199\,\frac{\text{kJ}}{\text{kg}}} = \boxed{48.8\,\text{g}}$$

32 •• You are supervising the creation of some lead castings for use in the construction industry. Each casting involves one of your workers pouring 0.500 kg of molten lead that has a temperature of 327ºC into a cavity in a large block of ice at 0ºC. How much liquid water should you plan on draining per hour if there are 100 workers who are able to each average one casting every 10.0 min?

Picture the Problem Because the heat lost by the lead as it cools is gained by the block of ice (we're assuming no heat is lost to the surroundings), we can apply the conservation of energy to determine how much ice melts.

Apply the conservation of energy to this process:

$$\Delta Q = \Delta Q_{\text{Pb}} + \Delta Q_{\text{W}} = 0$$

or

$$-m_{\text{Pb}}\left(L_{\text{f,Pb}} + c_{\text{Pb}}\Delta T_{\text{Pb}}\right) + m_{\text{w, 1 casting}}L_{\text{f,w}} = 0$$

Solving for m_w yields:

$$m_{\text{W, 1 casting}} = \frac{m_{\text{Pb}}\left(L_{\text{f,Pb}} + c_{\text{Pb}}\Delta T_{\text{Pb}}\right)}{L_{\text{f,W}}}$$

Because there are N workers each turning out n castings per hour:

$$m = nNm_{\text{W.1 casting}} = \frac{nNm_{\text{Pb}}\left(L_{\text{f,Pb}} + c_{\text{Pb}}\Delta T_{\text{Pb}}\right)}{L_{\text{f,W}}}$$

Substitute numerical values and evaluate m_w:

$$m = \frac{(100)(6)(0.500\,\text{kg})\left(24.7\,\frac{\text{kJ}}{\text{kg}} + \left(0.128\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(327°\text{C} - 0°\text{C})\right)}{333.5\,\frac{\text{kJ}}{\text{kg}}} \approx \boxed{60\,\text{kg}}$$

Calorimetry

33 • **[SSM]** While spending the summer on your uncle's horse farm, you spend a week apprenticing with his farrier (a person who makes and fits

horseshoes). You observe the way he cools a shoe after pounding the hot, pliable shoe into the correct size and shape. Suppose a 750-g iron horseshoe is taken from the farrier's fire, shaped, and at a temperature of 650°C, dropped into a 25.0-L bucket of water at 10.0°C. What is the final temperature of the water after the horseshoe and water arrive at equilibrium? Neglect any heating of the bucket and assume the specific heat of iron is $460\ \text{J/(kg}\cdot\text{K)}$.

Picture the Problem During this process the water will gain energy at the expense of the horseshoe. We can use conservation of energy to find the equilibrium temperature. See Table 18-1 for the specific heat of water.

Apply conservation of energy to obtain:

$$\sum_{\text{i}} Q_{\text{i}} = Q_{\text{warm the water}} + Q_{\text{cool the horseshoe}} = 0$$

or

$$m_{\text{water}}c_{\text{water}}\left(t_{\text{f}} - 10.0°\text{C}\right) + m_{\text{Fe}}c_{\text{Fe}}\left(t_{\text{f}} - 650°\text{C}\right) = 0$$

Solve for t_{f} to obtain:

$$t_{\text{f}} = \frac{m_{\text{water}}c_{\text{water}}\left(10.0°\text{C}\right) + m_{\text{Fe}}c_{\text{Fe}}\left(650°\text{C}\right)}{m_{\text{water}}c_{\text{water}} + m_{\text{Fe}}c_{\text{Fe}}}$$

Substitute numerical values and evaluate t_{f}:

$$t_{\text{f}} = \frac{\left(25.0\ \text{kg}\right)\left(4.184\ \frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\left(10.0°\text{C}\right) + \left(0.750\ \text{kg}\right)\left(0.460\ \frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\left(650°\text{C}\right)}{\left(25.0\ \text{kg}\right)\left(4.184\ \frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right) + \left(0.750\ \text{kg}\right)\left(0.460\ \frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)}$$

$$= \boxed{12.1°\text{C}}$$

34 • The specific heat of a certain metal can be determined by measuring the temperature change that occurs when a piece of the metal is heated and then placed in an insulated container that is made of the same material and contains water. Suppose the piece of metal has a mass of 100 g and is initially at 100ºC. The container has a mass of 200 g and contains 500 g of water at an initial temperature of 20.0ºC. The final temperature is 21.4ºC. What is the specific heat of the metal?

Picture the Problem During this process the water and the container will gain thermal energy at the expense of the piece of metal. Applying conservation of energy will lead to an expression you can solve for the specific heat of the metal.

Apply conservation of energy to obtain:

$$\sum_i Q_i = Q_{\text{warm the water}} + Q_{\text{warm the container}} + Q_{\text{cool the metal sample}} = 0$$

or

$$m_w c_w \Delta T_w + m_{\text{container}} c_{\text{metal}} \Delta T_w + m_{\text{metal}} c_{\text{metal}} \Delta T_{\text{metal}} = 0$$

Solving for c_{metal} yields:

$$c_{\text{metal}} = \frac{m_w c_w \Delta T_w}{m_{\text{metal}} \Delta T_{\text{metal}} - m_{\text{container}} \Delta T_w}$$

Substitute numerical values and evaluate c_{metal} :

$$c_{\text{metal}} = \frac{(0.500\,\text{kg})\left(4.184\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(21.4°\text{C} - 20.0°\text{C})}{(0.100\,\text{kg})(100°\text{C} - 21.4°\text{C}) - (0.200\,\text{kg})(21.4°\text{C} - 20.0°\text{C})}$$
$$= \boxed{0.39\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}}$$

Remarks: Consulting Table 18-1, we note that the metal is copper.

35 •• During his many appearances at the Tour de France, champion bicyclist Lance Armstrong typically expended an average power of 400 W, 5.0 hours a day for 20 days. What quantity of water, initially at 24ºC, could be brought to a boil if you could harness all of that energy?

Picture the Problem We can use $Q = mc\Delta T$ to express the mass m of water that can be heated through a temperature interval ΔT by an amount of heat energy Q. We can then find the amount of heat energy expended by Armstrong from the definition of power.

Express the amount of heat energy Q required to raise the temperature of a mass m of water by ΔT:

$$Q = mc\Delta T \Rightarrow m = \frac{Q}{c\Delta T}$$

Use the definition of power to relate the heat energy expended by Armstrong to the rate at which he expended the energy:

$$P = \frac{Q}{\Delta t} \Rightarrow Q = P\Delta t$$

Substitute for Q to obtain:

$$m = \frac{P\Delta t}{c\Delta T}$$

Substitute numerical values and evaluate m:

$$m = \frac{\left(400\,\frac{\text{J}}{\text{s}} \times \frac{3600\,\text{s}}{\text{h}}\right)\left(5.0\,\frac{\text{h}}{\text{d}} \times 20\,\text{d}\right)}{\left(4.184\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(100°\text{C} - 24°\text{C})} = \boxed{4.5\times10^{2}\,\text{kg}}$$

36 •• A 25.0-g glass tumbler contains 200 mL of water at 24.0ºC. If two 15.0-g ice cubes, each at a temperature of –3.00ºC, are dropped into the tumbler, what is the final temperature of the drink? Neglect any heat transfer between the tumbler and the room.

Picture the Problem First you need to convince yourself that there is enough energy in the water to melt all the ice. Once you've done that you can use conservation of energy to find the final equilibrium temperature. See Tables 18-1 and 18-2 for specific heats and the latent heat of fusion of water.

First, determine the energy required to warm and melt all the ice:

$$\begin{aligned}
Q_{\text{needed}} &= Q_{\text{warm ice}} + Q_{\text{melt ice}} = m_{\text{ice}}c_{\text{ice}}\Delta T_{\text{warm ice}} + m_{\text{ice}}L_{\text{f}} \\
&= (0.0300\,\text{kg})\left(2.05\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(3.00\,\text{C}°) + (0.0300\,\text{kg})(333.5\,\text{kJ/kg}) \\
&= 0.1845\,\text{kJ} + 10.01\,\text{kJ} = 10.19\,\text{kJ}
\end{aligned}$$

The maximum amount of energy available from the water and the tumbler is:

$$\begin{aligned}
Q_{\text{available, max}} &= m_{\text{tumbler}}c_{\text{glass}}\Delta T_{\text{max, tumbler}} + m_{\text{water}}c_{\text{water}}\Delta T_{\text{max, water}} \\
&= m_{\text{tumbler}}c_{\text{glass}}\Delta T_{\text{max, tumbler}} + \rho_{\text{water}}V_{\text{water}}c_{\text{water}}\Delta T_{\text{max, water}} \\
&= (0.0250\,\text{kg})\left(0.840\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(0°\text{C} - 24.0°\text{C}) \\
&\quad + \left(1.00\times10^{3}\,\frac{\text{kg}}{\text{m}^3}\right)\left(200\times10^{-3}\,\text{L}\times\frac{10^{-3}\,\text{m}^3}{\text{L}}\right)\left(4.184\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right) \\
&\quad \times(0°\text{C} - 24.0°\text{C}) \\
&= -0.5040\,\text{kJ} - 20.08\,\text{kJ} = -20.59\,\text{kJ}
\end{aligned}$$

Because $\left|Q_{\text{available, max}}\right| > Q_{\text{needed}}$, all the ice will melt and the final temperature will be greater than 0°C. Apply conservation of energy to obtain:

$$\sum_{\text{i}} Q_{\text{i}} = Q_{\text{cool the tumbler}} + Q_{\text{cool the warm water}} + Q_{\text{warm the ice}} + Q_{\text{melt all the ice}} + Q_{\text{warm the ice water}} = 0$$

or

$$m_{\text{tumbler}} c_{\text{glass}} \Delta T_{\text{tumbler}} + m_{\text{water}} c_{\text{water}} \Delta T_{\text{water}} + m_{\text{ice}} c_{\text{ice}} \Delta T_{\text{warn ice}} + m_{\text{ice}} L_{\text{f, ice}} + m_{\text{ice}} c_{\text{water}} \Delta T_{\text{ice water}} = 0$$

Substituting numerical values yields:

$$(0.0250\,\text{kg})\left(0.840\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(t_{\text{f}} - 24.0°\text{C}) + (0.200\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(t_{\text{f}} - 24.0°\text{C}) + 0.1845\,\text{kJ} + 10.01\,\text{kJ} + (0.0300\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(t_{\text{f}} - 0°\text{C}) = 0$$

Solving for t_{f} yields: $t_{\text{f}} = \boxed{10.6°\text{C}}$

37 •• [SSM] A 200-g piece of ice at 0ºC is placed in 500 g of water at 20ºC. This system is in a container of negligible heat capacity and is insulated from its surroundings. (*a*) What is the final equilibrium temperature of the system? (*b*) How much of the ice melts?

Picture the Problem Because we can not tell, without performing a couple of calculations, whether there is enough heat available in the 500 g of water to melt all of the ice, we'll need to resolve this question first. See Tables 18-1 and 18-2 for specific heats and the latent heat of fusion of water.

(*a*) Determine the energy required to melt 200 g of ice:

$$Q_{\text{melt ice}} = m_{\text{ice}} L_{\text{f}} = (0.200\,\text{kg})\left(333.5\frac{\text{kJ}}{\text{kg}}\right) = 66.70\,\text{kJ}$$

The energy available from 500 g of water at 20ºC is:

$$Q_{\text{available, max}} = m_{\text{water}} c_{\text{water}} \Delta T_{\text{water}} = (0.500\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(0°\text{C} - 20°\text{C}) = -41.84\,\text{kJ}$$

Because $\left|Q_{\text{available, max}}\right| < Q_{\text{melt ice}}$:

$$\boxed{\text{The final temperature is } 0°\text{C.}}$$

(*b*) Equate the energy available from the water $\left|Q_{\text{available, max}}\right|$ to $m_{\text{ice}}L_{\text{f}}$ and solve for m_{ice} to obtain:

$$m_{\text{ice}} = \frac{\left|Q_{\text{available, max}}\right|}{L_{\text{f}}}$$

Substitute numerical values and evaluate m_{ice}:

$$m_{\text{ice}} = \frac{41.84\,\text{kJ}}{333.5\,\frac{\text{kJ}}{\text{kg}}} = \boxed{125\,\text{g}}$$

38 •• A 3.5-kg block of copper at a temperature of 80ºC is dropped into a bucket containing a mixture of ice and water whose total mass is 1.2 kg. When thermal equilibrium is reached, the temperature of the water is 8.0ºC. How much ice was in the bucket before the copper block was placed in it? (Assume that the heat capacity of the bucket is negligible.)

Picture the Problem Because the bucket contains a mixture of ice and water initially, we know that its temperature must be 0°C. We can apply conservation of energy to find the amount of ice initially in the bucket. See Tables 18-1 and 18-2 for specific heats and the heats of fusion and vaporization of water.

Apply conservation of energy to obtain:

$$\sum_{\text{i}} Q_{\text{i}} = Q_{\substack{\text{melt all}\\ \text{the ice}}} + Q_{\substack{\text{warm the}\\ \text{ice water}}} + Q_{\substack{\text{cool the}\\ \text{copper block}}} = 0$$

Substitute for $Q_{\substack{\text{melt all}\\ \text{the ice}}}$, $Q_{\substack{\text{warm the}\\ \text{ice water}}}$, and $Q_{\substack{\text{cool the}\\ \text{copper block}}}$ to obtain:

$$m_{\text{ice}}L_{\text{f}} + m_{\text{ice water}}c_{\text{water}}\Delta T_{\text{ice water}} + m_{\text{Cu}}c_{\text{Cu}}\Delta T_{\text{Cu}} = 0$$

Solving for m_{ice} yields:

$$m_{\text{ice}} = \frac{m_{\text{Cu}}c_{\text{Cu}}\Delta T_{\text{Cu}} - m_{\text{ice water}}c_{\text{water}}\Delta T_{\text{ice water}}}{L_{\text{f}}}$$

Substitute numerical values and evaluate m_{ice}:

$$m_{ice} = \frac{(3.5\,\text{kg})\left(0.386\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(80°\text{C} - 8.0°\text{C})}{333.5\,\frac{\text{kJ}}{\text{kg}}} - \frac{(1.2\,\text{kg})\left(4.184\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(8.0°\text{C} - 0°\text{C})}{333.5\,\frac{\text{kJ}}{\text{kg}}}$$

$$= \boxed{0.17\,\text{kg}}$$

39 •• A well-insulated bucket of negligible heat capacity contains 150 g of ice at 0ºC. (*a*) If 20 g of steam at 100ºC is injected into the bucket, what is the final equilibrium temperature of the system? (*b*) Is any ice left after the system reaches equilibrium?

Picture the Problem First you need to convince yourself that there is enough energy in the steam to melt all the ice. Once you've done that you can use conservation of energy to find the final equilibrium temperature. See Tables 18-1 and 18-2 for specific heats and the heats of fusion and vaporization of water.

(*a*) First, determine the energy required to melt all the ice:

$$\begin{aligned} Q_{\text{melt ice}} &= m_{\text{ice}} L_f \\ &= (0.150\,\text{kg})(333.5\,\text{kJ/kg}) \\ &= 50.03\,\text{kJ} \end{aligned}$$

Find the maximum amount of energy available from the steam is:

$$\begin{aligned} Q_{\text{steam, max}} &= m_{\text{steam}} L_v + m_{\text{steam water}} c_{\text{water}} \Delta T_{\text{max}} \\ &= (0.020\,\text{kg})\left(2257\,\frac{\text{kJ}}{\text{kg}}\right) + (0.020\,\text{kg})\left(4.184\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(0°\text{C} - 100°\text{C}) \\ &= -45.14\,\text{kJ} - 8.37\,\text{kJ} = -53.51\,\text{kJ} \end{aligned}$$

Because $\left|Q_{\text{steam, max}}\right| > Q_{\text{melt ice}}$, all the ice will melt and the final temperature will be greater than 0°C. Apply conservation of energy to obtain:

$$\sum_i Q_i = Q_{\substack{\text{condense}\\ \text{steam}}} + Q_{\substack{\text{cool the}\\ \text{hot water}}} + Q_{\substack{\text{melt all}\\ \text{the ice}}} + Q_{\substack{\text{warm the}\\ \text{ice water}}} = 0$$

or

$$-45.14\,\text{kJ} + m_{\text{hot water}}c_{\text{water}}\left(t_\text{f} - 100°\text{C}\right) + 50.03\,\text{kJ} + m_{\text{ice}}c_{\text{water}}\left(t_\text{f} - 0°\text{C}\right) = 0$$

Substituting numerical values yields:

$$-45.14\,\text{kJ} + (0.020\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\left(t_\text{f} - 100°\text{C}\right) + 50.03\,\text{kJ} + (0.150\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\left(t_\text{f} - 0°\text{C}\right) = 0$$

Solving for t_f yields: $$t_\text{f} = \boxed{4.9°\text{C}}$$

(*b*) Because the final temperature is greater than 0°C, no ice is left.

40 •• A calorimeter of negligible heat capacity contains 1.00 kg of water at 303 K and 50.0 g of ice at 273 K. (*a*) Find the final temperature *T*. (*b*) Find the final temperature *T* if the mass of ice is 500 g.

Picture the Problem First you need to convince yourself that there is enough energy in the water to melt all the ice. Once you've done that you can use conservation of energy to find the final equilibrium temperature. See Tables 18-1 and 18-2 for specific heats and the heat of fusion of water.

(*a*) Find the heat available to melt the ice:

$$Q_{\text{available, max}} = m_{\text{water}}c_{\text{water}}\Delta T_{\text{water}} = (1.00\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(273\,\text{K} - 303\,\text{K})$$
$$= -125.5\,\text{kJ}$$

Find the heat required to melt all of the ice:

$$Q_{\text{melt ice}} = m_{\text{ice}}L_\text{f} = (0.0500\,\text{kg})\left(333.5\frac{\text{kJ}}{\text{kg}}\right) = 16.68\,\text{kJ}$$

Because $\left|Q_{\text{available, max}}\right| > Q_{\text{melt ice}}$, we know that the final temperature will be greater than 273 K. Apply conservation of energy to obtain:

$$\sum_\text{i} Q_\text{i} = Q_{\substack{\text{cool the}\\\text{warm water}}} + Q_{\substack{\text{melt all}\\\text{the ice}}} + Q_{\substack{\text{warm the}\\\text{ice water}}} = 0$$

or

$$(1.00\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(T-303\,\text{K})+16.68\,\text{kJ}$$
$$+(0.0500\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(T-273\,\text{K})=0$$

Solving for T_f yields: $T_f = \boxed{298\,\text{K}}$

(*b*) Find the heat required to melt 500 g of ice:

$$Q_{\text{melt ice}} = m_{\text{ice}}L_f = (0.500\,\text{kg})(333.5\,\text{kJ/kg}) \approx 167\,\text{kJ}$$

Because the heat required to melt 500 g of ice is greater than the heat available, the final temperature will be 0°C.

41 •• A 200-g aluminum calorimeter contains 600 g of water at 20.0ºC. A 100-g piece of ice cooled to –20.0ºC is placed in the calorimeter. (*a*) Find the final temperature of the system, assuming no heat is transferred to or from the system. (*b*) A 200-g piece of ice at –20.0ºC is added. How much ice remains in the system after the system reaches equilibrium? (*c*) Would the answer for Part (*b*) change if both pieces of ice were added at the same time?

Picture the Problem First you need to convince yourself that there is enough energy in the water and the calorimeter to melt all the ice. Once you've done that you can use conservation of energy to find the final equilibrium temperature in (*a*). In Part (*b*) you can find the energy required to raise the temperature of the 200 g of ice to 0°C and then, noting that there are now 700 g of water in the calorimeter, find the energy available from cooling the calorimeter and water from their equilibrium temperature to 0°C. Finally, you can find the amount of ice that will melt in terms of the difference between the energy available and the energy required to warm the ice. See Tables 18-1 and 18-2 for specific heats and the latent heat of fusion of water.

Find the energy available to melt the ice:

$$Q_{\text{available, max}} = \left|m_{\text{water}}c_{\text{water}}\Delta T_{\text{water}} + m_{\text{cal}}c_{\text{cal}}\Delta T_{\text{water}}\right| = \left|(m_{\text{water}}c_{\text{water}} + m_{\text{cal}}c_{\text{cal}})\Delta T_{\text{water}}\right|$$
$$= \left|\left[(0.600\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)+(0.200\,\text{kg})\left(0.900\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\right](0°\text{C}-20.0°\text{C})\right|$$
$$= 53.81\,\text{kJ}$$

Find the energy required to warm and melt all of the ice:

$$\begin{aligned}
Q_{\substack{\text{warm and}\\ \text{melt the ice}}} &= m_{\text{ice}}c_{\text{ice}}\Delta T_{\text{ice}} + m_{\text{ice}}L_{\text{f}} \\
&= (0.100\,\text{kg})\left(2.05\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(0°\text{C}-(-20.0°\text{C})) + (0.100\,\text{kg})\left(333.5\frac{\text{kJ}}{\text{kg}}\right) \\
&= 37.45\,\text{kJ}
\end{aligned}$$

(*a*) Because $Q_{\text{available, max}} > Q_{\text{melt ice}}$, we know that the final temperature will be greater than 0°C. Apply conservation of energy to obtain:

$$\sum_{\text{i}} Q_{\text{i}} = Q_{\substack{\text{cool the}\\ \text{calorimeter}}} + Q_{\substack{\text{cool the}\\ \text{warm water}}} + Q_{\substack{\text{warm and}\\ \text{melt the ice}}} + Q_{\substack{\text{warm the}\\ \text{ice water}}} = 0$$

or, using the results from our preliminary calculations,

$$\begin{aligned}
m_{\text{calorimeter}}c_{\text{Cu}}(t_{\text{f}} - 20.0°\text{C}) + m_{\text{water}}c_{\text{water}}(t_{\text{f}} - 20.0°\text{C}) + 37.45\,\text{kJ} \\
+ m_{\text{ice}}c_{\text{water}}(t_{\text{f}} - 0°\text{C}) = 0
\end{aligned}$$

Substituting numerical values yields:

$$\begin{aligned}
(0.200\,\text{kg})\left(0.900\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(t_{\text{f}} - 20.0°\text{C}) + (0.600\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(t_{\text{f}} - 20.0°\text{C}) \\
+ 37.45\,\text{kJ} + (0.100\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)t_{\text{f}} = 0
\end{aligned}$$

Solve for t_{f} to obtain: $t_{\text{f}} = 5.262°\text{C} = \boxed{5.26°\text{C}}$

(*b*) The mass of ice remaining in the system when equilibrium is reached is the difference between the initial mass of ice and the mass of the ice that has melted:

$$m_{\substack{\text{ice}\\ \text{remaining}}} = m_{\substack{\text{ice}\\ \text{initially}}} - m_{\substack{\text{ice}\\ \text{melted}}} = m_{\substack{\text{ice}\\ \text{initially}}} - \frac{Q_{\text{avail}} - Q_{\substack{\text{warm ice}\\ \text{to 0°C}}}}{L_{\text{f}}} \quad (1)$$

Find the energy required to raise the temperature of the 200 g of ice to 0°C:

$$Q_{\substack{\text{warm ice}\\ \text{to 0°C}}} = m_{\text{ice}}c_{\text{ice}}\Delta T_{\text{ice}} = (0.200\,\text{kg})\left(2.02\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(0°\text{C}-(-20.0°\text{C})) = 8.080\,\text{kJ}$$

Noting that there are now 700 g of water in the calorimeter, find the energy available from cooling the calorimeter and water from 5.262°C to 0°C:

$$\begin{aligned} Q_{\text{avail}} &= m_{\text{water}}c_{\text{water}}\Delta T_{\text{water}} + m_{\text{cal}}c_{\text{cal}}\Delta T_{\text{water}} = \left(m_{\text{water}}c_{\text{water}} + m_{\text{cal}}c_{\text{cal}}\right)\Delta T_{\text{water}} \\ &= \left[(0.700\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right) + (0.200\,\text{kg})\left(0.900\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\right](5.262\text{°C} - 0\text{°C}) \\ &= 16.359\,\text{kJ} \end{aligned}$$

Substitute numerical values in equation (1) and evaluate $m_{\substack{\text{ice}\\\text{remaining}}}$:

$$m_{\substack{\text{ice}\\\text{remaining}}} = 200\text{ g} - \frac{16.359\,\text{kJ} - 8.080\,\text{kJ}}{333.5\,\text{kJ/kg}} = \boxed{200\text{ g}}$$

(*c*) No. Because the initial and final conditions are the same, the answer would be the same.

42 •• The specific heat of a 100-g block of a substance is to be determined. The block is placed in a 25-g copper calorimeter holding 60 g of water initially at 20ºC. Then, 120 mL of water at 80ºC are added to the calorimeter. When thermal equilibrium is reached, the temperature of the system is 54ºC. Determine the specific heat of the block.

Picture the Problem Let the subscript B denote the block, w_1 the water initially in the calorimeter, and w_2 the 120 mL of water that is added to the calorimeter vessel. We can use conservation of energy to find the specific heat of the block. See Table 18-1 for specific heats.

Apply conservation of energy to obtain:

$$\sum_{\text{i}} Q_{\text{i}} = Q_{\substack{\text{warm}\\\text{the block}}} + Q_{\substack{\text{warm the}\\\text{calorimeter}}} + Q_{\text{warm } w_1} + Q_{\text{cool } w_2} = 0$$

or

$$m_{\text{B}}c_{\text{B}}\Delta T + m_{\text{Cu}}c_{\text{Cu}}\Delta T + m_{w_1}c_{w_1}\Delta T + m_{w_2}c_{w_2}\Delta T_{w_2} = 0$$

where ΔT is the common temperature change of the calorimeter, block, and water initially in the calorimeter.

Substitute numerical values to obtain:

$$(0.100\,\text{kg})\boldsymbol{c}_{\text{B}}(54°\text{C}-20°\text{C})+(0.025\,\text{kg})\left(0.386\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(54°\text{C}-20°\text{C})$$
$$+(0.060\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(54°\text{C}-20°\text{C})$$
$$+(0.120\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(54°\text{C}-80°\text{C})=0$$

Solving for c_{B} yields: $$c_{\text{B}}=\boxed{1.2\,\text{kJ/kg}\cdot\text{K}}$$

43 •• [SSM] A 100-g piece of copper is heated in a furnace to a temperature t_{C}. The copper is then inserted into a 150-g copper calorimeter containing 200 g of water. The initial temperature of the water and calorimeter is 16.0ºC, and the temperature after equilibrium is established is 38.0ºC. When the calorimeter and its contents are weighed, 1.20 g of water are found to have evaporated. What was the temperature t_{C}?

Picture the Problem We can find the temperature t by applying conservation of energy to this calorimetry problem. See Tables 18-1 and 18-2 for specific heats and the heat of vaporization of water.

Use conservation of energy to obtain:

$$\sum_{\text{i}} Q_{\text{i}} = Q_{\substack{\text{vaporize}\\ \text{water}}} + Q_{\substack{\text{warm}\\ \text{the water}}} + Q_{\substack{\text{warm the}\\ \text{calorimeter}}} + Q_{\substack{\text{cool the}\\ \text{Cu sample}}} = 0$$

or

$$m_{\text{H}_2\text{O, vaporized}}L_{\text{f, w}} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\Delta T_{\text{H}_2\text{O}} + m_{\text{cal}}c_{\text{cal}}\Delta T_{\text{w}} + m_{\text{Cu}}c_{\text{Cu}}\Delta T_{\text{Cu}} = 0$$

Substituting numerical values yields:

$$(1.20\,\text{g})\left(2257\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)+(200\,\text{g})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(38.0°\text{C}-16.0°\text{C})$$
$$+(150\,\text{g})\left(0.386\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(38.0°\text{C}-16.0°\text{C})$$
$$+(100\,\text{g})\left(0.386\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(38.0°\text{C}-t_{\text{C}})=0$$

Solving for t_{C} yields: $$t_{\text{C}}=\boxed{618°\text{C}}$$

44 •• A 200-g aluminum calorimeter contains 500 g of water at 20.0ºC. Aluminum shot with a mass equal to 300 g is heated to 100.0ºC and is then placed in the calorimeter. Find the final temperature of the system, assuming that there is no heat is transfer to the surroundings.

Picture the Problem We can find the final temperature by applying conservation of energy to the calorimeter, the water in the calorimeter, and to the cooling aluminum shot. See Table 18-1 for the specific heats of aluminum and water.

Use conservation of energy to obtain:

$$\sum_{\text{i}} Q_{\text{i}} = Q_{\substack{\text{warm the}\\ \text{water}}} + Q_{\substack{\text{warm the}\\ \text{calorimeter}}} + Q_{\substack{\text{cool the}\\ \text{Al shot}}} = 0$$

or

$$\left[m_{\text{w}}c_{\text{w}} + m_{\text{cal}}c_{\text{Al}}\right]\Delta T + m_{\text{shot}}c_{\text{Al}}\Delta T_{\text{Al}} = 0$$

where ΔT is the common temperature change of the water and calorimeter.

Substituting numerical values yields:

$$\left[(0.500\,\text{kg})\left(4.184\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right) + (0.200\,\text{kg})\left(0.900\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\right](t_{\text{f}} - 20.0°\text{C})$$
$$+ (0.300\,\text{kg})\left(0.900\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(t_{\text{f}} - 100°\text{C}) = 0$$

Solving for t_{f} gives:

$$t_{\text{f}} = \boxed{28.5°\text{C}}$$

First Law of Thermodynamics

45 • A diatomic gas does 300 J of work and also absorbs 2.50 kJ of heat. What is the change in internal energy of the gas?

Picture the Problem We can apply the first law of thermodynamics to find the change in internal energy of the gas during this process.

Apply the first law of thermodynamics to express the change in internal energy of the gas in terms of the heat added to the system and the work done on the gas:

$$\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$$

The work done by the gas equals the negative of the work done on the gas. Substitute numerical values and evaluate ΔE_{int}:

$$\Delta \boldsymbol{E}_{int} = 2.50\ \text{kJ} - 300\ \text{J} = \boxed{2.20\ \text{kJ}}$$

46 • If a gas absorbs 1.67 MJ of heat while doing 800 kJ of work, what is the change in the internal energy of the gas?

Picture the Problem We can apply the first law of thermodynamics to find the change in internal energy of the gas during this process.

Apply the first law of thermodynamics to express the change in internal energy of the gas in terms of the heat added to the system and the work done on the gas:

$$\Delta E_{int} = Q_{in} + W_{on}$$

The work done by the gas is the negative of the work done on the gas. Substitute numerical values and evaluate ΔE_{int}:

$$\Delta E_{int} = 1.67\ \text{MJ} - 800\ \text{kJ} = \boxed{0.87\ \text{MJ}}$$

47 • If a gas absorbs 84 J while doing 30 J of work, what is the change in the internal energy of the gas?

Picture the Problem We can apply the first law of thermodynamics to find the change in internal energy of the gas during this process.

Apply the first law of thermodynamics to express the change in internal energy of the gas in terms of the heat added to the system and the work done on the gas:

$$\Delta E_{int} = Q_{in} + W_{on}$$

The work done by the gas is the negative of the work done on the gas. Substitute numerical values and evaluate ΔE_{int}:

$$\Delta E_{int} = 84\ \text{J} - 30\ \text{J} = \boxed{54\ \text{J}}$$

48 •• A lead bullet initially at 30ºC just melts upon striking a target. Assuming that all of the initial kinetic energy of the bullet goes into the internal energy of the bullet, calculate the impact speed of the bullet.

Picture the Problem We can use the definition of kinetic energy to express the speed of the bullet upon impact in terms of its kinetic energy. The heat absorbed by the bullet is the sum of the heat required to warm the bullet from 303 K to its melting temperature of 600 K and the heat required to melt it. We can use the first law of thermodynamics to relate the impact speed of the bullet to the change in its internal energy. See Table 18-1 for the specific heat and melting temperature of lead.

Using the first law of thermodynamics, relate the change in the internal energy of the bullet to the work done on it by the target:

$$\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$$

or, because $Q_{\text{in}} = 0$,

$$\Delta E_{\text{int}} = W_{\text{on}} = \Delta K = -(K_{\text{f}} - K_i)$$

Substitute for ΔE_{int}, K_{f}, and K_{i} to obtain:

$$mc_{\text{Pb}}\Delta T_{\text{Pb}} + mL_{\text{f,Pb}} = -\left(0 - \tfrac{1}{2}mv^2\right) = \tfrac{1}{2}mv^2$$

or

$$mc_{\text{Pb}}(T_{\text{MP}} - T_{\text{i}}) + mL_{\text{f,Pb}} = \tfrac{1}{2}mv^2$$

Solving for v yields:

$$v = \sqrt{2\left[c_{\text{Pb}}(T_{\text{MP}} - T_{\text{i}}) + L_{\text{f,Pb}}\right]}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{2\left\{\left(0.128\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(600\,\text{K} - 303\,\text{K}) + 24.7\frac{\text{kJ}}{\text{kg}}\right\}} = \boxed{354\,\text{m/s}}$$

49 •• During a cold day, you can warm your hands by rubbing them together. Assume the coefficient of kinetic friction between your hands is 0.500, the normal force between your hands is 35.0 N, and that you rub them together at an average relative speed of 35.0 cm/s. (*a*) What is the rate at which mechanical energy is dissipated? (*b*) Assume further that the mass of each of your hands is 350 g, the specific heat of your hands is 4.00 kJ/kg·K, and that all the dissipated mechanical energy goes into increasing the temperature of your hands. How long must you rub your hands together to produce a 5.00°C increase in their temperature?

Picture the Problem We can find the rate at which heat is generated when you rub your hands together using the definition of power and the rubbing time to produce a 5.00°C increase in temperature from $\Delta Q = (dQ/dt)\Delta t$ and $Q = mc\Delta T$.

(*a*) The rate at which heat is generated as a function of the friction force and the average relative speed of your hands is given by:

$$\frac{dQ}{dt} = P = f_k v = \mu F_n v$$

Substitute numerical values and evaluate dQ/dt:

$$\frac{dQ}{dt} = (0.500)(35.0\,\text{N})(0.350\,\text{m/s})$$
$$= 6.125\ \text{W} = \boxed{6.13\,\text{W}}$$

(*b*) Relate the heat required to raise the temperature of your hands $5.00°\text{C}$ to the rate at which it is being generated:

$$\Delta Q = \frac{dQ}{dt}\Delta t = mc\Delta T \Rightarrow \Delta t = \frac{mc\Delta T}{dQ/dt}$$

Substitute numerical values and evaluate Δt:

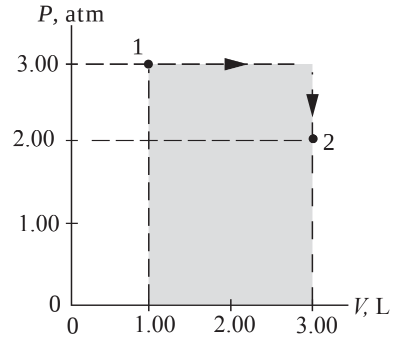
$$\Delta t = \frac{2(0.350\,\text{kg})\left(4.00\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(5.00\,\text{C}°)}{6.125\,\text{W}}$$
$$= 2286\,\text{s} \times \frac{1\,\text{min}}{60\,\text{s}} = \boxed{38.1\,\text{min}}$$

Work and the *PV* Diagram for a Gas

50 • The gas is allowed to expand at constant pressure until it reaches its final volume. It is then cooled at constant volume until it reaches its final pressure. (*a*) Illustrate this process on a *PV* diagram and calculate the work done by the gas. (*b*) Find the heat absorbed by the gas during this process.

Picture the Problem We can find the work done by the gas during this process from the area under the curve. Because no work is done along the constant volume (vertical) part of the path, the work done by the gas is done during its isobaric expansion. We can then use the first law of thermodynamics to find the heat added to the system during this process.

(*a*) The path from the initial state (1) to the final state (2) is shown on the *PV* diagram.



The work done by the gas equals the area under the shaded curve:

$$W_{\text{by gas}} = P\Delta V = (3.00\,\text{atm})(2.00\,\text{L}) = \left(3.00\,\text{atm}\times\frac{101.325\,\text{kPa}}{\text{atm}}\right)\left(2.00\,\text{L}\times\frac{10^{-3}\,\text{m}^3}{\text{L}}\right)$$
$$= \boxed{608\,\text{J}}$$

(*b*) The work done by the gas is the negative of the work done on the gas. Apply the first law of thermodynamics to the system to obtain:

$$\begin{aligned} Q_{\text{in}} &= \Delta E_{\text{int}} - W_{\text{on}} \\ &= \left(E_{\text{int},2} - E_{\text{int},1}\right) - \left(-W_{\text{by gas}}\right) \\ &= \left(E_{\text{int},2} - E_{\text{int},1}\right) + W_{\text{by gas}} \end{aligned}$$

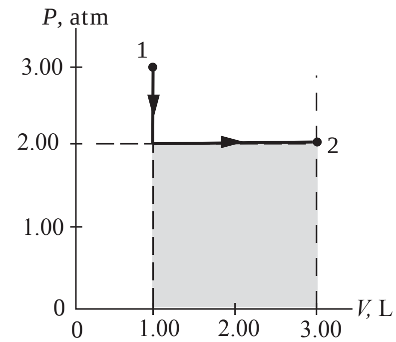
Substitute numerical values and evaluate Q_{in}:

$$\begin{aligned} Q_{\text{in}} &= (912\,\text{J} - 456\,\text{J}) + 608\,\text{J} \\ &= \boxed{1.06\,\text{kJ}} \end{aligned}$$

51 • [SSM] The gas is first cooled at constant volume until it reaches its final pressure. It is then allowed to expand at constant pressure until it reaches its final volume. (*a*) Illustrate this process on a *PV* diagram and calculate the work done by the gas. (*b*) Find the heat absorbed by the gas during this process.

Picture the Problem We can find the work done by the gas during this process from the area under the curve. Because no work is done along the constant volume (vertical) part of the path, the work done by the gas is done during its isobaric expansion. We can then use the first law of thermodynamics to find the heat absorbed by the gas during this process

(*a*) The path from the initial state (1) to the final state (2) is shown on the *PV* diagram.



The work done by the gas equals the area under the curve:

$$W_{\text{by gas}} = P\Delta V = (2.00\,\text{atm})(2.00\,\text{L}) = \left(2.00\,\text{atm}\times\frac{101.325\,\text{kPa}}{\text{atm}}\right)\left(2.00\,\text{L}\times\frac{10^{-3}\,\text{m}^3}{\text{L}}\right)$$
$$= \boxed{405\,\text{J}}$$

(*b*) The work done by the gas is the negative of the work done on the gas. Apply the first law of thermodynamics to the system to obtain:

$$Q_{\text{in}} = \Delta E_{\text{int}} - W_{\text{on}}$$
$$= \left(E_{\text{int,2}} - E_{\text{int,1}}\right) - \left(-W_{\text{by gas}}\right)$$
$$= \left(E_{\text{int,2}} - E_{\text{int,1}}\right) + W_{\text{by gas}}$$

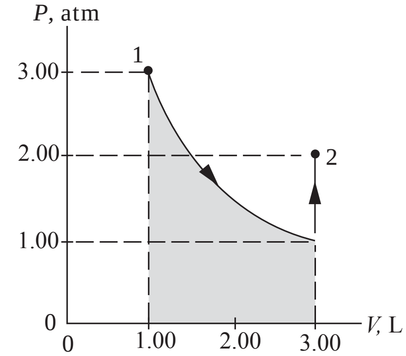
Substitute numerical values and evaluate Q_{in}:

$$Q_{\text{in}} = (912\,\text{J} - 456\,\text{J}) + 405\,\text{J} = \boxed{861\,\text{J}}$$

52 •• The gas is allowed to expand isothermally until it reaches its final volume and its pressure is 1.00 atm. It is then heated at constant volume until it reaches its final pressure. (*a*) Illustrate this process on a *PV* diagram and calculate the work done by the gas. (*b*) Find the heat absorbed by the gas during this process.

Picture the Problem We can find the work done by the gas during this process from the area under the curve. Because no work is done along the constant volume (vertical) part of the path, the work done by the gas is done during its isothermal expansion. We can then use the first law of thermodynamics to find the heat absorbed by the gas during this process.

(*a*) The path from the initial state (1) to the final state (2) is shown on the *PV* diagram.



The work done by the gas equals the area under the curve:

$$W_{\text{by gas}} = \int_{V_1}^{V_2} PdV = nRT_1 \int_{1\,\text{L}}^{3\,\text{L}} \frac{dV}{V}$$

$$= P_1V_1 \int_{1.00\,\text{L}}^{3.00\,\text{L}} \frac{dV}{V} = P_1V_1\left[\ln V\right]_{1.00\,\text{L}}^{3.00\,\text{L}}$$

$$= P_1V_1 \ln 3$$

Substitute numerical values and evaluate $W_{\text{by gas}}$:

$$W_{\text{by gas}} = \left(3.00\,\text{atm} \times \frac{101.325\,\text{kPa}}{\text{atm}}\right)\left(1.00\,\text{L} \times \frac{10^{-3}\,\text{m}^3}{\text{L}}\right)\ln 3 = \boxed{334\,\text{J}}$$

(*b*) The work done by the gas is the negative of the work done on the gas. Apply the first law of thermodynamics to the system to obtain:

$$Q_{\text{in}} = \Delta E_{\text{int}} - W_{\text{on}}$$
$$= \left(E_{\text{int},2} - E_{\text{int},1}\right) - \left(-W_{\text{by gas}}\right)$$
$$= \left(E_{\text{int},2} - E_{\text{int},1}\right) + W_{\text{by gas}}$$

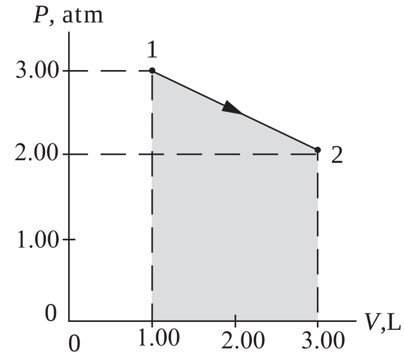
Substitute numerical values and evaluate Q_{in}:

$$Q_{\text{in}} = \left(912\,\text{J} - 456\,\text{J}\right) + 334\,\text{J} = \boxed{790\,\text{J}}$$

53 •• The gas is heated and is allowed to expand such that it follows a single straight-line path on a *PV* diagram from its initial state to its final state. (*a*) Illustrate this process on a *PV* diagram and calculate the work done by the gas. (*b*) Find the heat absorbed by the gas during this process.

Picture the Problem We can find the work done by the gas during this process from the area under the curve. We can then use the first law of thermodynamics to find the heat absorbed by the gas during this process.

(*a*) The path from the initial state (1) to the final state (2) is shown on the *PV* diagram:



The work done by the gas equals the area under the curve:

$$\begin{aligned} W_{\text{by gas}} &= A_{\text{trapezoid}} \\ &= \tfrac{1}{2}(3.00\,\text{atm} + 2.00\,\text{atm})(2.00\,\text{L}) \\ &= 5.00\,\text{atm}\cdot\text{L} \times \frac{101.325\,\text{J}}{\text{atm}\cdot\text{L}} \\ &= \boxed{507\,\text{J}} \end{aligned}$$

(*b*) The work done by the gas is the negative of the work done on the gas. Apply the first law of thermodynamics to the system to obtain:

$$\begin{aligned} Q_{\text{in}} &= \Delta E_{\text{int}} - W_{\text{on}} \\ &= (E_{\text{int},2} - E_{\text{int},1}) - (-W_{\text{by gas}}) \\ &= (E_{\text{int},2} - E_{\text{int},1}) + W_{\text{by gas}} \end{aligned}$$

Substitute numerical values and evaluate Q_{in}:

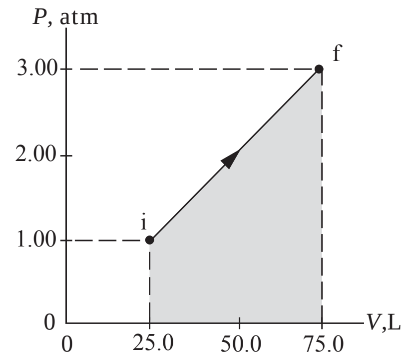
$$Q_{\text{in}} = (912\,\text{J} - 456\,\text{J}) + 507\,\text{J} = \boxed{963\,\text{J}}$$

Remarks: You could use the linearity of the path connecting the initial and final states and the coordinates of the endpoints to express *P* as a function of *V*. You could then integrate this function between 1.00 and 3.00 L to find the work done by the gas as it goes from its initial to its final state.

54 •• In this problem, 1.00 mol of a dilute gas initially has a pressure equal to 1.00 atm, a volume equal to 25.0 L and an internal energy equal to 456 J. As the gas is slowly heated, the plot of its state on a *PV* diagram moves in a straight line to the final state. The gas now has a pressure equal to 3.00 atm, a volume equal to 75.0 L and an internal energy equal to 912 J. Find the work done and the heat absorbed by the gas.

Picture the Problem We can find the work done by the gas during this process from the area under the curve and the heat absorbed by the gas from the 1$^{\text{st}}$ law of thermodynamics.

The path from the initial state i to the final state f is shown on the PV diagram:



The work done by the gas equals the area under the curve:

$$\begin{aligned}W_{\text{by gas}} &= A_{\text{trapezoid}} \\ &= \tfrac{1}{2}(1.00\,\text{atm} + 3.00\,\text{atm}) \\ &\qquad \times (75.0\,\text{L} - 25.0\,\text{L}) \\ &= 100\,\text{atm}\cdot\text{L} \times \frac{101.325\,\text{J}}{\text{atm}\cdot\text{L}} \\ &= \boxed{10.1\,\text{kJ}}\end{aligned}$$

The work done by the gas is the negative of the work done on the gas. Apply the first law of thermodynamics to the system to obtain:

$$\begin{aligned}Q_{\text{in}} &= \Delta E_{\text{int}} - W_{\text{on}} \\ &= (E_{\text{int},2} - E_{\text{int},1}) - (-W_{\text{by gas}}) \\ &= (E_{\text{int},2} - E_{\text{int},1}) + W_{\text{by gas}}\end{aligned}$$

Substitute numerical values and evaluate Q_{in}:

$$Q_{\text{in}} = (912\,\text{J} - 456\,\text{J}) + 10.1\,\text{kJ} = \boxed{10.6\,\text{kJ}}$$

Remarks: You could use the linearity of the path connecting the initial and final states and the coordinates of the endpoints to express *P* as a function of *V*. You could then integrate this function between 25.0 and 75.0 L to find the work done by the gas as it goes from its initial to its final state.

55 •• In this problem, 1.00 mol of the ideal gas is heated while its volume changes, so that $T = AP^2$, where A is a constant. The temperature changes from T_0 to $4T_0$. Find the work done by the gas.

Picture the Problem We can find the work done by the gas from the area under the PV curve provided we can find the pressure and volume coordinates of the initial and final states. We can find these coordinates by using the ideal gas law and the condition $T = AP^2$.

Apply the ideal-gas law with $n =$ 1.00 mol and $T = AP^2$ to obtain:

$$PV = RAP^2 \Rightarrow V = RAP \qquad (1)$$

This result tells us that the volume varies linearly with the pressure.

Solve $T = AP^2$ for the pressure of the gas:

$$P_0 = \sqrt{\frac{T_0}{A}}$$

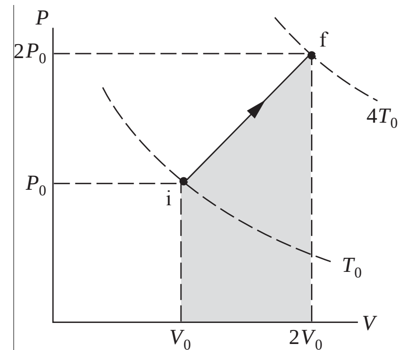
Find the pressure when the temperature is $4T_0$:

$$P = \sqrt{\frac{4T_0}{A}} = 2\sqrt{\frac{T_0}{A}} = 2P_0$$

Using equation (1), express the coordinates of the final state:

$$(2V_0, 2P_0)$$

The PV diagram for the process is shown to the right:



The work done by the gas equals the area under the curve:

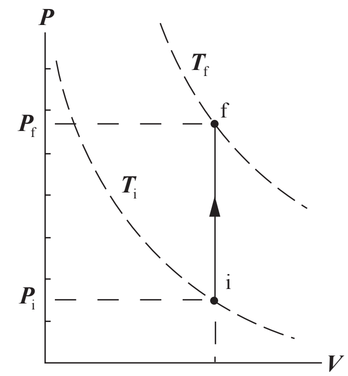
$$W_{\text{by gas}} = A_{\text{trapezoid}} = \tfrac{1}{2}(P_0 + 2P_0)(2V_0 - V_0)$$
$$= \boxed{\tfrac{3}{2}P_0V_0}$$

56 •• A sealed, almost-empty spray paint can still contains a residual amount of the propellant: 0.020 mol of nitrogen gas. The can's warning label clearly states: "Do Not Dispose by Incineration." (*a*) Explain this warning and draw the *PV* diagram for the gas if, in fact, the can is subject to a high temperature. (*b*) You are in charge of testing the can. The manufacturer claims it can withstand an internal gas pressure of 6.00 atm before it breaks. The can is initially at room-temperature and standard pressure in your testing laboratory. You begin to heat it uniformly using a heating element that has a power output of 200 W. The can and element are in an insulating oven, and you can assume 1.0% of the heat released by the heating element is absorbed by the gas in the can. How long should you expect the heating element to remain on before the can bursts?

Picture the Problem This is a constant-volume process and so no work is done on the system. The heat that is added to the gas by the heating element increases the internal energy (and, hence, the temperature) of the gas. We can use the definition of power to relate the minimum time-to-bursting to the internal energy required to raise the temperature of the gas in the can and the rate at which energy is supplied by the heating element. The energy required to burst the can is related

to the increase in the temperature of the can through the definition of the heat capacity at constant volume C_v.

(*a*) Because the volume of the can is fixed (constant), the heat absorbed by the gas in the can all goes into increasing the internal energy of the gas and, thus, its temperature. At constant volume, the pressure rise is the maximum possible, threatening the structural integrity of the can and possibly leading to a grenade-like shrapnel explosion.



(*b*) The heating time required to burst the container is related to the rate at which the heating element delivers energy to it:

$$\Delta t = \frac{\Delta Q}{P}$$

The heat that the heating element must supply to the gas is given by:

$$\Delta Q = C_v \Delta T = \tfrac{5}{2} nR\Delta T$$

Substituting for ΔQ yields:

$$\Delta t = \frac{\frac{5}{2} nR\Delta T}{P} = \frac{5nR\Delta T}{2P} \qquad (1)$$

The temperature difference that corresponds to the bursting threshold is given by:

$$\Delta T = T_f - T_i \qquad (2)$$

Apply the ideal-gas law to the gas in the can to obtain:

$$\frac{P_i V_i}{T_i} = \frac{P_f V_f}{T_f}$$

or, because $V_i = V_f$,

$$\frac{P_i}{T_i} = \frac{P_f}{T_f}$$

Solving for the ratio of the final temperature to the initial temperature yields:

$$\frac{T_f}{T_i} = \frac{P_f}{P_i} = 6 \Rightarrow T_f = 6T_i$$

Substitute for T_f in equation (2) and evaluate ΔT:

$$\Delta T = 6T_i - T_i = 5T_i$$

Substituting for ΔT in equation (1) yields:

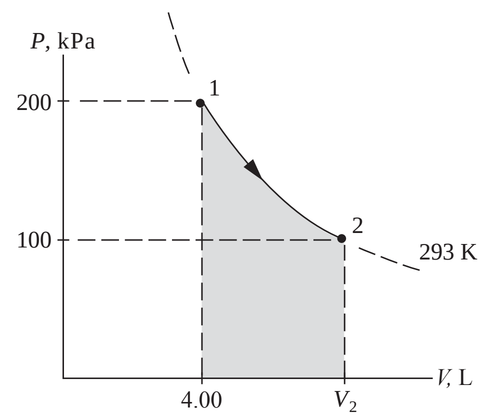
$$\Delta t = \frac{25nRT_i}{2P}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{25(0.020\ \text{mol})\left(8.314\ \frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(293\ \text{K})}{2(0.010)(200\ \text{W})} = 305\ \text{s}\cdot\frac{1\ \text{min}}{60\ \text{s}} = \boxed{5.1\ \text{min}}$$

57 •• [SSM] An ideal gas initially at 20ºC and 200 kPa has a volume of 4.00 L. It undergoes a quasi-static, isothermal expansion until its pressure is reduced to 100 kPa. Find (*a*) the work done by the gas, and (*b*) the heat absorbed by the gas during the expansion.

Picture the Problem The *PV* diagram shows the isothermal expansion of the ideal gas from its initial state 1 to its final state 2. We can use the ideal-gas law for a fixed amount of gas to find V_2 and then evaluate $\int PdV$ for an isothermal process to find the work done by the gas. In Part (*b*) of the problem we can apply the first law of thermodynamics to find the heat added to the gas during the expansion.



(*a*) Express the work done by a gas during an isothermal process:

$$W_{\text{by gas}} = \int_{V_1}^{V_2} PdV = nRT\int_{V_1}^{V_2}\frac{dV}{V} = P_1V_1\int_{V_1}^{V_2}\frac{dV}{V}$$

Apply the ideal-gas law for a fixed amount of gas undergoing an isothermal process:

$$P_1V_1 = P_2V_2 \Rightarrow V_2 = \frac{P_1}{P_2}V_1$$

Substitute numerical values and evaluate V_2:

$$V_2 = \frac{200\ \text{kPa}}{100\ \text{kPa}}(4.00\ \text{L}) = 8.00\ \text{L}$$

Substitute numerical values and evaluate W:

$$W_{\text{by gas}} = (200\ \text{kPa})(4.00\ \text{L})\int_{4.00\ \text{L}}^{8.00\ \text{L}} \frac{dV}{V} = (800\ \text{kPa}\cdot\text{L})[\ln V]_{4.00\ \text{L}}^{8.00\ \text{L}}$$

$$= (800\ \text{kPa}\cdot\text{L})\ln\left(\frac{8.00\ \text{L}}{4.00\ \text{L}}\right) = 554.5\ \text{kPa}\cdot\text{L}\times\frac{10^{-3}\ \text{m}^3}{\text{L}}$$

$$= \boxed{555\ \text{J}}$$

(*b*) Apply the first law of thermodynamics to the system to obtain:

$$Q_{\text{in}} = \Delta E_{\text{int}} - W_{\text{on}}$$

or, because $\Delta E_{\text{int}} = 0$ for an isothermal process,

$$Q_{\text{in}} = -W_{\text{on}}$$

Because the work done by the gas is the negative of the work done on the gas:

$$Q_{\text{in}} = -(-W_{\text{by gas}}) = W_{\text{by gas}} = \boxed{555\ \text{J}}$$

Remarks: in an isothermal expansion the heat added to the gas is always equal to the work done by the gas ($\Delta E_{\text{int}} = 0$).

Heat Capacities of Gases and the Equipartition Theorem

58 • The heat capacity at constant volume of a certain amount of a monatomic gas is 49.8 J/K. (*a*) Find the number of moles of the gas. (*b*) What is the internal energy of the gas at $T = 300$ K? (*c*) What is the heat capacity at constant pressure of the gas?

Picture the Problem We can find the number of moles of the gas from its heat capacity at constant volume using $C_{\text{V}} = \frac{3}{2}nR$. We can find the internal energy of the gas from $E_{\text{int}} = C_{\text{V}}T$ and the heat capacity at constant pressure using $C_{\text{P}} = C_{\text{V}} + nR$.

(*a*) Express C_{V} in terms of the number of moles in the monatomic gas:

$$C_{\text{V}} = \tfrac{3}{2}nR \Rightarrow n = \frac{2C_{\text{V}}}{3R}$$

Substitute numerical values and evaluate n:

$$n = \frac{2\left(49.8\,\frac{\text{J}}{\text{K}}\right)}{3\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)} = 3.993\ \text{mol} = \boxed{3.99\ \text{mol}}$$

(b) The internal energy of the gas is related to its temperature:

$$E_{\text{int}} = C_{\text{V}}T$$

Substitute numerical values and evaluate E_{int}:

$$E_{\text{int}} = \left(49.8\,\frac{\text{J}}{\text{K}}\right)(300\ \text{K}) = \boxed{14.9\ \text{kJ}}$$

(c) Relate the heat capacity at constant pressure to the heat capacity at constant volume:

$$C_{\text{P}} = C_{\text{V}} + nR = \tfrac{3}{2}nR + nR = \tfrac{5}{2}nR$$

Substitute numerical values and evaluate C_{P}:

$$C_{\text{P}} = \tfrac{5}{2}(3.993\ \text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right) = \boxed{83.0\ \text{J/K}}$$

59 •• [SSM] The heat capacity at constant pressure of a certain amount of a diatomic gas is 14.4 J/K. (a) Find the number of moles of the gas. (b) What is the internal energy of the gas at $T = 300$ K? (c) What is the molar heat capacity of this gas at constant volume? (d) What is the heat capacity of this gas at constant volume?

Picture the Problem (a) The number of moles of the gas is related to its heat capacity at constant pressure and its molar heat capacity at constant pressure according to $C_{\text{P}} = nc'_{\text{P}}$. For a diatomic gas, the molar heat capacity at constant pressure is $c'_{\text{P}} = \tfrac{7}{2}R$. ($b$) The internal energy of a gas depends on its number of degrees of freedom and, for a diatomic gas, is given by $E_{\text{int}} = \tfrac{5}{2}nRT$. ($c$) The molar heat capacity of this gas at constant volume is related to its molar heat capacity at constant pressure according to $c'_{\text{V}} = c'_{\text{P}} - R$. ($d$) The heat capacity of this gas at constant volume is the product of the number of moles in the gas and its molar heat capacity at constant volume.

(a) The number of moles of the gas is the ratio of its heat capacity at constant pressure to its molar heat capacity at constant pressure:

$$n = \frac{C_{\text{P}}}{c'_{\text{P}}}$$

For a diatomic gas, the molar heat capacity is given by:

$$c'_P = \tfrac{7}{2}R = 29.1\,\frac{\text{J}}{\text{mol}\cdot\text{K}}$$

Substitute numerical values and evaluate n:

$$n = \frac{14.4\,\frac{\text{J}}{\text{K}}}{29.1\,\frac{\text{J}}{\text{mol}\cdot\text{K}}} = 0.4948\ \text{mol} = \boxed{0.495\ \text{mol}}$$

(*b*) With 5 degrees of freedom at this temperature:

$$E_{\text{int}} = \tfrac{5}{2}nRT$$

Substitute numerical values and evaluate E_{int}:

$$E_{\text{int}} = \tfrac{5}{2}(0.4948\ \text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(300\ \text{K}) = \boxed{3.09\ \text{kJ}}$$

(*c*) The molar heat capacity of this gas at constant volume is the difference between the molar heat capacity at constant pressure and the gas constant R:

$$c'_V = c'_P - R$$

Because $c'_P = \tfrac{7}{2}R$ for a diatomic gas:

$$c'_V = \tfrac{7}{2}R - R = \tfrac{5}{2}R$$

Substitute the numerical value of R to obtain:

$$c'_V = \tfrac{5}{2}\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right) = 20.79\,\frac{\text{J}}{\text{mol}\cdot\text{K}} = \boxed{20.8\,\frac{\text{J}}{\text{mol}\cdot\text{K}}}$$

(*d*) The heat capacity of this gas at constant volume is given by:

$$C'_V = nc'_V$$

Substitute numerical values and evaluate $\boldsymbol{C'_V}$:

$$C'_V = (0.4948\ \text{mol})\left(20.79\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right) = \boxed{10.3\,\frac{\text{J}}{\text{K}}}$$

60 •• (*a*) Calculate the heat capacity per unit mass of air at constant volume and the heat capacity per unit mass of air at constant pressure. Assume that air has a temperature of 300 K and a pressure of $1.00 \times 10^5\ \text{N/m}^2$. Also assume that air is

composed of 74.0% N_2 molecules (molecular weight 28.0 g/mol) and 26.0% O_2 molecules (molar mass of 32.0 g/mol) and that both components are ideal gases. (*b*) Compare your answer for the specific heat at constant pressure to the value listed in the *Handbook of Chemistry and Physics* of 1.032 kJ/kg·K.

Picture the Problem The specific heats of air at constant volume and constant pressure are given by $c_V = C_V/m$ and $c_P = C_P/m$ and the heat capacities at constant volume and constant pressure are given by $C_V = \frac{5}{2}nR$ and $C_P = \frac{7}{2}nR$, respectively.

(*a*) Express the heat capacity per unit mass of air at constant volume and constant pressure:

$$c_V = \frac{C_V}{m} \quad (1)$$

and

$$c_P = \frac{C_P}{m} \quad (2)$$

Express the heat capacities of a diatomic gas in terms of the gas constant R, the number of moles n, and the number of degrees of freedom:

$$C_V = \tfrac{5}{2}nR$$

and

$$C_P = \tfrac{7}{2}nR$$

The mass of 1.00 mol of air is given by:

$$m = 0.74M_{N_2} + 0.26M_{O_2}$$

Substitute for C_V and m in equation (1) to obtain:

$$c_V = \frac{5nR}{2\left(0.74M_{N_2} + 0.26M_{O_2}\right)}$$

Substitute numerical values and evaluate c_V:

$$c_V = \frac{5(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)}{2\left[(0.740)\left(28.0\times10^{-3}\,\text{kg}\right)+(0.260)\left(32.0\times10^{-3}\,\text{kg}\right)\right]} = \boxed{716\,\frac{\text{J}}{\text{kg}\cdot\text{K}}}$$

Substitute for C_P and m in equation (2) to obtain:

$$c_P = \frac{7nR}{2\left(0.74M_{N_2} + 0.26M_{O_2}\right)}$$

Substitute numerical values and evaluate c_P:

$$c_P = \frac{7(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)}{2\left[(0.740)(28.0\times10^{-3}\,\text{kg})+(0.260)(32.0\times10^{-3}\,\text{kg})\right]} = \boxed{1.00\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}}$$

(*b*) The percent difference between the value from the *Handbook of Chemistry and Physics* and the calculated value is:

$$\frac{1.032\,\text{kJ/kg}\cdot\text{K} - 1.00\,\text{kJ/kg}\cdot\text{K}}{1.032\,\text{J/kg}\cdot\text{K}} \approx \boxed{3\%}$$

61 •• In this problem, 1.00 mol of an ideal diatomic gas is heated at constant volume from 300 to 600 K. (*a*) Find the increase in the internal energy of the gas , the work done by the gas, and the heat absorbed by the gas. (*b*) Find the same quantities if this gas is heated from 300 to 600 K at constant pressure. Use the first law of thermodynamics and your results for (*a*) to calculate the work done by the gas. (*c*) Again calculate the work done in Part (*b*). This time calculate it by integrating the equation $dW = P\,dV$.

Picture the Problem (*a*) We know that, during a constant-volume process, no work is done and that we can calculate the heat added during this expansion from the heat capacity at constant volume and the change in the absolute temperature. We can then use the first law of thermodynamics to find the change in the internal energy of the gas. In Part (*b*), we can proceed similarly; using the heat capacity at constant pressure rather than constant volume.

(*a*) The increase in the internal energy of a fixed amount of an ideal diatomic gas depends only on its change in temperature as it goes from one state to another:

$$\Delta E_{\text{int}} = \tfrac{5}{2} nR\Delta T$$

Substitute numerical values and evaluate ΔE_{int}:

$$\Delta E_{\text{int}} = \tfrac{5}{2}(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(300\,\text{K}) = 6.236\,\text{kJ} = \boxed{6.24\,\text{kJ}}$$

For a constant-volume process:

$$W_{\text{on}} = \boxed{0}$$

From the 1st law of thermodynamics we have:

$$Q_{in} = \Delta E_{int} - W_{on} = 6.24\,\text{kJ} - 0 = \boxed{6.24\,\text{kJ}}$$

(*b*) Because ΔE_{int} depends only on the temperature difference:

$$\Delta E_{int} = \boxed{6.24\,\text{kJ}}$$

Relate the heat added to the gas to its heat capacity at constant pressure and the change in its temperature:

$$Q_{in} = C_P \Delta T = \left(\tfrac{5}{2}nR + nR\right)\Delta T = \tfrac{7}{2}nR\Delta T$$

Substitute numerical values and evaluate Q_{in}:

$$Q_{in} = \tfrac{7}{2}(1.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(300\,\text{K}) = 8.730\,\text{kJ} = \boxed{8.73\,\text{kJ}}$$

Apply the first law of thermodynamics to find W:

$$W_{on} = \Delta E_{int} - Q_{in} = 8.730\,\text{kJ} - 6.236\,\text{kJ} = \boxed{2.49\,\text{kJ}}$$

(*c*) Integrate $dW_{on} = P\,dV$ to obtain:

$$W_{on} = \int_{V_i}^{V_f} PdV = P(V_f - V_i) = nR(T_f - T_i)$$

Substitute numerical values and evaluate W_{on}:

$$W_{on} = (1.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(300\,\text{K}) = \boxed{2.49\,\text{kJ}}$$

62 •• A diatomic gas is confined to a closed container of constant volume V_0 and at a pressure P_0. The gas is heated until its pressure triples. What amount of heat had to be absorbed by the gas in order to triple the pressure?

Picture the Problem Because this is a constant-volume process, we can use $Q = C_V\Delta T$ to express Q in terms of the temperature change and the ideal-gas law for a fixed amount of gas to find ΔT.

Express the amount of heat Q that must be absorbed by the gas if its pressure is to triple:

$$Q = C_V\Delta T = \tfrac{5}{2}nR(T_f - T_0)$$

Using the ideal-gas law for a fixed amount of gas, relate the initial and final temperatures, pressures and volumes:

$$\frac{P_0V_0}{T_0}=\frac{3P_0V_0}{T_f}\Rightarrow T_f=3T_0$$

Substitute for T_f and simplify to obtain:

$$Q=\tfrac{5}{2}nR(3T_0-T_0)=5(nRT_0)=\boxed{5P_0V_0}$$

63 •• In this problem, 1.00 mol of air is confined in a cylinder with a piston. The confined air is maintained at a constant pressure of 1.00 atm. The air is initially at 0ºC and has volume V_0. Find the volume after 13,200 J of heat are absorbed by the trapped air.

Picture the Problem Let the subscripts i and f refer to the initial and final states of the gas, respectively. We can use the ideal-gas law for a fixed amount of gas to express V' in terms of V and the change in temperature of the gas when 13,200 J of heat are transferred to it. We can find this change in temperature using $Q=C_p\Delta T$.

Using the ideal-gas law for a fixed amount of gas, relate the initial and final temperatures, volumes, and pressures:

$$\frac{P_iV}{T_i}=\frac{P_fV'}{T_f}$$

Noting that the process is isobaric, solve for V' to obtain:

$$V'=V\frac{T_f}{T_i}=V\frac{T_i+\Delta T}{T_i}=V\left(1+\frac{\Delta T}{T_i}\right)$$

Relate the heat transferred to the gas to the change in its temperature:

$$Q=C_p\Delta T=\tfrac{7}{2}nR\Delta T\Rightarrow\Delta T=\frac{2Q}{7nR}$$

Substitute for ΔT to obtain:

$$V'=V\left(1+\frac{2Q}{7nRT_i}\right)$$

One mol of gas at standard temperature and pressure occupies 22.4 L. Substitute numerical values and evaluate V':

$$V'=(22.4\,\text{L})\left(1+\frac{2(13.2\,\text{kJ})}{7(1.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(273\,\text{K})}\right)=\boxed{59.6\,\text{L}}$$

64 •• The heat capacity at constant pressure of a sample of gas is greater than the heat capacity at constant volume by 29.1 J/K. (*a*) How many moles of the gas are present? (*b*) If the gas is monatomic, what are C_v and C_p? (*c*) What are the values of C_v and C_p at normal room temperatures?

Picture the Problem We can use the relationship between C_P and C_V ($C_P = C_V + nR$) to find the number of moles of this particular gas. In Parts (*b*) and (*c*) we can use the number of degrees of freedom associated with monatomic and diatomic gases, respectively, to find C_P and C_V.

(*a*) Express the heat capacity of the gas at constant pressure to its heat capacity at constant volume:

$$C_P = C_V + nR \Rightarrow n = \frac{C_P - C_V}{R}$$

Substitute numerical values and evaluate *n*:

$$n = \frac{29.1\,\frac{\text{J}}{\text{K}}}{8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}} = 3.500\,\text{mol}$$

$$= \boxed{3.50\,\text{mol}}$$

(*b*) C_V for a monatomic gas is given by:

$$C_V = \tfrac{3}{2}nR$$

Substitute numerical values and evaluate C_V:

$$C_V = \tfrac{3}{2}(3.500\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)$$

$$= 43.65\ \text{J/K} = \boxed{43.6\,\text{J/K}}$$

Express C_P for a monatomic gas:

$$C_P = \tfrac{5}{2}nR$$

Substitute numerical values and evaluate C_P:

$$C_P = \tfrac{5}{2}(3.500\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)$$

$$= \boxed{72.7\,\text{J/K}}$$

(*c*) At normal room temperature, if the diatomic molecules rotate but do not vibrate they have 5 degrees of freedom. Hence:

$$C_V = \tfrac{5}{2}nR$$

and

$$C_P = C_V + R = \tfrac{7}{2}nR$$

Substitute numerical values and evaluate C_V and C_P:

$$C_V = \tfrac{5}{2}(3.500\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right) = \boxed{72.7\,\text{J/K}}$$

and

$$C_P = \tfrac{7}{2}(3.500\,\text{mol})(8.314\,\text{J/mol}\cdot\text{K}) = \boxed{102\,\text{J/K}}$$

65 •• **[SSM]** Carbon dioxide (CO_2) at a pressure of 1.00 atm and a temperature of –78.5ºC sublimates directly from a solid to a gaseous state without going through a liquid phase. What is the change in the heat capacity at constant pressure per mole of CO_2 when it undergoes sublimation? (Assume that the gas molecules can rotate but do not vibrate.) Is the change in the heat capacity positive or negative during sublimation? The CO_2 molecule is pictured in Figure 18-22.

Picture the Problem We can find the change in the heat capacity at constant pressure as CO_2 undergoes sublimation from the energy per molecule of CO_2 in the solid and gaseous states.

Express the change in the heat capacity (at constant pressure) per mole as the CO_2 undergoes sublimation:

$$\Delta C_P = C_{P,\text{gas}} - C_{P,\text{solid}} \qquad (1)$$

Express $C_{p,\text{gas}}$ in terms of the number of degrees of freedom per molecule:

$$C_{P,\text{gas}} = f\left(\tfrac{1}{2}Nk\right) = \tfrac{5}{2}Nk$$

because each molecule has three translational and two rotational degrees of freedom in the gaseous state.

We know, from the Dulong-Petit Law, that the molar specific heat of most solids is $3R = 3Nk$. This result is essentially a per-atom result as it was obtained for a monatomic solid with six degrees of freedom. Use this result and the fact CO_2 is triatomic to express $C_{P,\text{solid}}$:

$$C_{P,\text{solid}} = \frac{3Nk}{\text{atom}} \times 3\,\text{atoms} = 9Nk$$

Substitute in equation (1) to obtain:

$$\Delta C_P = \tfrac{5}{2}Nk - \tfrac{18}{2}Nk = \boxed{-\tfrac{13}{2}Nk}$$

66 •• In this problem, 1.00 mol of a monatomic ideal gas is initially at 273 K and 1.00 atm. (*a*) What is the initial internal energy of the gas? (*b*) Find the work done by the gas when 500 J of heat are absorbed by the gas at constant pressure.

What is the final internal energy of the gas? (*c*) Find the work done by the gas when 500 J of heat are absorbed by the gas at constant volume. What is the final internal energy of the gas?

Picture the Problem We can find the initial internal energy of the gas from $U_\mathrm{i} = \frac{3}{2}nRT$ and the final internal energy from the change in internal energy resulting from the addition of 500 J of heat. The work done during a constant-volume process is zero and the work done during the constant-pressure process can be found from the first law of thermodynamics.

(*a*) Express the initial internal energy of the gas in terms of its temperature:

$$E_\mathrm{int,i} = \tfrac{3}{2}nRT$$

Substitute numerical values and evaluate $E_\mathrm{int,i}$:

$$E_\mathrm{int,i} = \tfrac{3}{2}(1.00\,\mathrm{mol})\left(8.314\frac{\mathrm{J}}{\mathrm{mol\cdot K}}\right)(273\,\mathrm{K}) = 3.405\,\mathrm{kJ} = \boxed{3.40\,\mathrm{kJ}}$$

(*b*) Relate the final internal energy of the gas to its initial internal energy:

$$E_\mathrm{int,f} = E_\mathrm{int,i} + \Delta E_\mathrm{int} = E_\mathrm{int,i} + C_\mathrm{V}\Delta T$$

Express the change in temperature of the gas resulting from the addition of heat:

$$\Delta T = \frac{Q_\mathrm{in}}{C_\mathrm{P}}$$

Substitute to obtain:

$$E_\mathrm{int,f} = E_\mathrm{int,i} + \frac{C_\mathrm{V}}{C_\mathrm{P}}Q_\mathrm{in}$$

Substitute numerical values and evaluate $E_\mathrm{int,f}$:

$$E_\mathrm{int,f} = 3.405\,\mathrm{kJ} + \left(\frac{\frac{3}{2}nR}{\frac{5}{2}nR}\right)(500\,\mathrm{J}) = 3.705\,\mathrm{kJ} = \boxed{3.71\,\mathrm{kJ}}$$

The work done by the gas is the negative of the work done on the gas and is related to the change in internal energy and the heat added to the gas through the first law of thermodynamics:

$$\begin{aligned} W_\text{by gas} &= -W_\mathrm{on} = -\Delta E_\mathrm{int} + Q_\mathrm{in} \\ &= -\left(E_\mathrm{int,f} - E_\mathrm{int,i}\right) + Q_\mathrm{in} \\ &= -E_\mathrm{int,f} + E_\mathrm{int,i} + Q_\mathrm{in} \end{aligned}$$

Substitute numerical values and evaluate $W_{\text{by gas}}$:

$$W_{\text{by gas}} = -3.71\,\text{kJ} + 3.40\,\text{kJ} + 500\,\text{J} = \boxed{0.19\,\text{kJ}}$$

(*c*) Relate the final internal energy of the gas to its initial internal energy:

$$E_{\text{int,f}} = E_{\text{int,i}} + \Delta E_{\text{int}}$$

Apply the first law of thermodynamics to the constant-volume process:

$$\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$$

or, because $W_{\text{on}} = 0$,

$$\Delta E_{\text{int}} = Q_{\text{in}} = 500\,\text{J}$$

Substitute numerical values and evaluate $E_{\text{int,f}}$:

$$E_{\text{int,f}} = 3.405\,\text{kJ} + 500\,\text{J} = \boxed{3.91\,\text{kJ}}$$

and, because $W_{\text{on}} = 0 = -W_{\text{by gas}}$,

$$W_{\text{by gas}} = \boxed{0}$$

67 •• List all of the degrees of freedom possible for a water molecule and estimate the heat capacity of water at a temperature very far above its boiling point. (Ignore the fact the molecule might dissociate at high temperatures.) Think carefully about all of the different ways in which a water molecule can vibrate.

Picture the Problem We can use $C_{\text{V,water}} = f\left(\frac{1}{2}Nk\right)$ to express $C_{\text{V,water}}$ and then count the number of degrees of freedom associated with a water molecule to determine *f*.

Express $C_{\text{V,water}}$ in terms of the number of degrees of freedom per molecule:

$$C_{\text{V,water}} = f\left(\tfrac{1}{2}Nk\right)$$

where *f* is the number of degrees of freedom associated with a water molecule.

There are 3 translational degrees of freedom and three rotational degrees of freedom. In addition, each of the hydrogen atoms can vibrate against the oxygen atom, resulting in an additional 4 degrees of freedom (2 per atom).

Substitute for *f* to obtain:

$$C_{\text{V,water}} = 10\left(\tfrac{1}{2}Nk\right) = \boxed{5Nk} = \boxed{5nR}$$

Heat Capacities of Solids and the Dulong-Petit Law

68 • The Dulong–Petit law was originally used to determine the molar mass of a substance from its measured heat capacity. The specific heat of a certain solid substance is measured to be 0.447 kJ/kg·K. (*a*) Find the molar mass of the substance. (*b*) What element has this specific heat value?

Picture the Problem The Dulong-Petit law gives the molar specific heat of a solid, c'. The specific heat is defined as $c = c'/M$ where M is the molar mass. Hence we can use this definition to find M and a periodic table to identify the element.

(*a*) Apply the Dulong-Petit law:

$$c' = 3R \Rightarrow c = \frac{3R}{M} \Rightarrow M = \frac{3R}{c}$$

Substitute numerical values and evaluate M:

$$M = \frac{24.9\,\frac{\text{J}}{\text{mol}\cdot\text{K}}}{0.447\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}} = \boxed{55.7\,\text{g/mol}}$$

(*b*) Consulting the periodic table of elements we see that the element is most likely $\boxed{\text{iron}}$.

Quasi-Static Adiabatic Expansion of a Gas

69 •• [SSM] A 0.500-mol sample of an ideal monatomic gas at 400 kPa and 300 K, expands quasi-statically until the pressure decreases to 160 kPa. Find the final temperature and volume of the gas, the work done by the gas, and the heat absorbed by the gas if the expansion is (*a*) isothermal and (*b*) adiabatic.

Picture the Problem We can use the ideal-gas law to find the initial volume of the gas. In Part (*a*) we can apply the ideal-gas law for a fixed amount of gas to find the final volume and the expression for the work done in an isothermal process. Application of the first law of thermodynamics will allow us to find the heat absorbed by the gas during this process. In Part (*b*) we can use the relationship between the pressures and volumes for a quasi-static adiabatic process to find the final volume of the gas. We can apply the ideal-gas law to find the final temperature and, as in (*a*), apply the first law of thermodynamics, this time to find the work done by the gas.

Use the ideal-gas law to express the initial volume of the gas:

$$V_i = \frac{nRT_i}{P_i}$$

Substitute numerical values and evaluate V_i:

$$V_i = \frac{(0.500\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(300\,\text{K})}{400\,\text{kPa}} = 3.118\times10^{-3}\ \text{m}^3$$

(*a*) Because the process is isothermal:

$$T_f = T_i = \boxed{300\,\text{K}}$$

Use the ideal-gas law for a fixed amount of gas with T constant to express V_f:

$$P_iV = P_fV_f \Rightarrow V_f = V_i\frac{P_i}{P_f}$$

Substitute numerical values and evaluate V_f:

$$V_f = (3.118\,\text{L})\left(\frac{400\,\text{kPa}}{160\,\text{kPa}}\right) = 7.795\,\text{L}$$
$$= \boxed{7.80\,\text{L}}$$

Express the work done by the gas during the isothermal expansion:

$$W_{\text{by gas}} = nRT\ln\frac{V_f}{V_i}$$

Substitute numerical values and evaluate $W_{\text{by gas}}$:

$$W_{\text{by gas}} = (0.500\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)\times(300\,\text{K})\ln\left(\frac{7.795\,\text{L}}{3.118\,\text{L}}\right)$$
$$= \boxed{1.14\,\text{kJ}}$$

Noting that the work done by the gas during the process equals the negative of the work done on the gas, apply the first law of thermodynamics to find the heat absorbed by the gas:

$$Q_{\text{in}} = \Delta E_{\text{int}} - W_{\text{on}} = 0 - (-1.14\,\text{kJ})$$
$$= \boxed{1.14\,\text{kJ}}$$

(*b*) Using $\gamma = 5/3$ and the relationship between the pressures and volumes for a quasi-static adiabatic process, express V_f:

$$P_iV_i^\gamma = P_fV_f^\gamma \Rightarrow V_f = V_i\left(\frac{P_i}{P_f}\right)^{1/\gamma}$$

Substitute numerical values and evaluate V_f:

$$V_f = (3.118\,\text{L})\left(\frac{400\,\text{kPa}}{160\,\text{kPa}}\right)^{3/5} = 5.403\,\text{L}$$
$$= \boxed{5.40\,\text{L}}$$

Apply the ideal-gas law to find the final temperature of the gas:

$$T_f = \frac{P_fV_f}{nR}$$

Substitute numerical values and evaluate T_f:

$$T_f = \frac{(160\,\text{kPa})(5.403\times10^{-3}\,\text{m}^3)}{(0.500\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)} = \boxed{208\,\text{K}}$$

For an adiabatic process:

$$Q_{\text{in}} = \boxed{0}$$

Apply the first law of thermodynamics to express the work done on the gas during the adiabatic process:

$$W_{\text{on}} = \Delta E_{\text{int}} - Q_{\text{in}} = C_V\Delta T - 0 = \tfrac{3}{2}nR\Delta T$$

Substitute numerical values and evaluate W_{on}:

$$W_{\text{on}} = \tfrac{3}{2}(0.500\,\text{mol})(8.314\,\text{J/mol}\cdot\text{K})\times(208\,\text{K}-300\,\text{K}) = -574\,\text{J}$$

Because the work done by the gas equals the negative of the work done on the gas:

$$W_{\text{by gas}} = -(-574\,\text{J}) = \boxed{574\,\text{J}}$$

70 •• A 0.500-mol sample of an ideal diatomic gas at 400 kPa and 300 K expands until the pressure decreases to 160 kPa. Find the final temperature and volume of the gas, the work done by the gas, and the heat absorbed by the gas if the expansion is (*a*) isothermal and (*b*) adiabatic.

Picture the Problem We can use the ideal-gas law to find the initial volume of the gas. In Part (*a*) we can apply the ideal-gas law for a fixed amount of gas to find the final volume and the expression for the work done in an isothermal process. Application of the first law of thermodynamics will allow us to find the heat absorbed by the gas during this process. In Part (*b*) we can use the relationship between the pressures and volumes for a quasi-static adiabatic process to find the final volume of the gas. We can apply the ideal-gas law to find the final temperature and, as in (*a*), apply the first law of thermodynamics, this time to find the work done by the gas.

Use the ideal-gas law to express the initial volume of the gas:

$$V_i = \frac{nRT_i}{P_i}$$

Substitute numerical values and evaluate V_i:

$$V_i = \frac{(0.500\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(300\,\text{K})}{400\,\text{kPa}} = 3.118\,\text{L}$$

(*a*) Because the process is isothermal:

$$T_f = T_i = \boxed{300\,\text{K}}$$

Use the ideal-gas law for a fixed amount of gas with T = constant to express V_f:

$$P_iV_i = P_fV_f \Rightarrow V_f = V_i\frac{P_i}{P_f}$$

Substitute numerical values and evaluate T_f:

$$V_f = (3.118\,\text{L})\left(\frac{400\,\text{kPa}}{160\,\text{kPa}}\right) = 7.795\,\text{L} = \boxed{7.80\,\text{L}}$$

Express the work done by the gas during the isothermal expansion:

$$W_{\text{by gas}} = nRT\ln\frac{V_f}{V_i}$$

Substitute numerical values and evaluate $W_{\text{by gas}}$:

$$W_{\text{by gas}} = (0.500\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)\times(300\,\text{K})\ln\left(\frac{7.795\,\text{L}}{3.118\,\text{L}}\right) = \boxed{1.14\,\text{kJ}}$$

Noting that the work done by the gas during the isothermal expansion equals the negative of the work done on the gas, apply the first law of thermodynamics to find the heat absorbed by the gas:

$$Q_{\text{in}} = \Delta E_{\text{int}} - W_{\text{on}} = 0 - (-1.14\,\text{kJ}) = \boxed{1.14\,\text{kJ}}$$

(*b*) Using γ = 1.4 and the relationship between the pressures and volumes for a quasi-static adiabatic process, express V_f:

$$P_iV_i^\gamma = P_fV_f^\gamma \Rightarrow V_f = V_i\left(\frac{P_i}{P_f}\right)^{1/\gamma}$$

Substitute numerical values and evaluate V_f:

$$V_f = (3.118\,\text{L})\left(\frac{400\,\text{kPa}}{160\,\text{kPa}}\right)^{1/1.4} = 6.000\,\text{L}$$
$$= \boxed{6.00\,\text{L}}$$

Apply the ideal-gas law to express the final temperature of the gas:

$$T_f = \frac{P_f V_f}{nR}$$

Substitute numerical values and evaluate T_f:

$$T_f = \frac{(160\,\text{kPa})(6.000\times10^{-3}\,\text{m}^3)}{(0.500\,\text{mol})(8.314\,\text{J/mol}\cdot\text{K})}$$
$$= \boxed{231\,\text{K}}$$

For an adiabatic process:

$$Q_{\text{in}} = \boxed{0}$$

Apply the first law of thermodynamics to express the work done on the gas during the adiabatic expansion:

$$W_{\text{on}} = \Delta E_{\text{int}} - Q_{\text{in}} = C_V \Delta T - 0 = \tfrac{5}{2} nR\Delta T$$

Substitute numerical values and evaluate W_{on}:

$$W_{\text{on}} = \tfrac{5}{2}(0.500\,\text{mol})(8.314\,\text{J/mol}\cdot\text{K}) \times (231\,\text{K} - 300\,\text{K})$$
$$= -717\,\text{J}$$

Noting that the work done by the gas during the adiabatic expansion is the negative of the work done on the gas, we have:

$$W_{\text{by gas}} = -(-717\,\text{J}) = \boxed{717\,\text{J}}$$

71 •• A 0.500-mol sample of helium gas expands adiabatically and quasi-statically from an initial pressure of 5.00 atm and temperature of 500 K to a final pressure of 1.00 atm. Find (*a*) the final temperature of the gas, (*b*) the final volume of the gas, (*c*) the work done by the gas, and (*d*) the change in the internal energy of the gas.

Picture the Problem We can eliminate the volumes from the equations relating the temperatures and volumes and the pressures and volumes for a quasi-static adiabatic process to obtain a relationship between the temperatures and pressures. We can find the initial volume of the gas using the ideal-gas law and the final volume using the pressure-volume relationship. In Parts (*d*) and (*c*) we can find the change in the internal energy of the gas from the change in its temperature and use the first law of thermodynamics to find the work done by the gas during its expansion.

(*a*) Express the relationship between temperatures and volumes for a quasi-static adiabatic process:

$$T_i V_i^{\gamma-1} = T_f V_f^{\gamma-1}$$

Express the relationship between pressures and volumes for a quasi-static adiabatic process:

$$P_i V_i^{\gamma} = P_f V_f^{\gamma} \qquad (1)$$

Eliminate the volume between these two equations to obtain:

$$T_f = T_i\left(\frac{P_f}{P_i}\right)^{1-\frac{1}{\gamma}}$$

Substitute numerical values and evaluate T_f:

$$T_f = (500\,\text{K})\left(\frac{1.00\,\text{atm}}{5.00\,\text{atm}}\right)^{1-\frac{1}{5/3}} = \boxed{263\,\text{K}}$$

(*b*) Solve equation (1) for V_f:

$$V_f = V_i\left(\frac{P_i}{P_f}\right)^{\frac{1}{\gamma}}$$

Apply the ideal-gas law to express V_i:

$$V_i = \frac{nRT_i}{P_i}$$

Substitute numerical values and evaluate V_i:

$$V_i = \frac{(0.500\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(500\,\text{K})}{5.00\text{atm}\times\frac{101.325\,\text{kPa}}{\text{atm}}} = 4.103\,\text{L}$$

Substitute for V_i and evaluate V_f:

$$V_f = (4.103\,\text{L})\left(\frac{5.00\,\text{atm}}{1.00\,\text{atm}}\right)^{\frac{3}{5}} = \boxed{10.8\,\text{L}}$$

(*c*) The work done by the gas during an adiabatic expansion is the negative of the work done on the gas during the expansion:

$$W_{\text{by the gas}} = -W_{\text{on}} = -(\Delta E_{\text{int}} - Q_{\text{in}}) = -(\Delta E_{\text{int}} - 0) = -\Delta E_{\text{int}}$$

Because $\Delta E_{\text{int}} = C_V \Delta T = \frac{3}{2} nR\Delta T$:

$$W_{\text{by the gas}} = -\tfrac{3}{2} nR\Delta T$$

Substitute numerical values and evaluate $W_{\text{by the gas}}$:

$$W_{\text{by the gas}} = -\tfrac{3}{2}(0.500\text{ mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(263\text{ K} - 500\text{ K}) = \boxed{1.48\text{ kJ}}$$

(*d*) Apply the first law of thermodynamics for an adiabatic process to obtain:

$$\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}} = 0 + (-W_{\text{by the gas}}) = -W_{\text{by the gas}}$$

Substitute $W_{\text{by the gas}}$ from (*c*):

$$\Delta E_{\text{int}} = -(1.48\text{ kJ}) = \boxed{-1.48\text{ kJ}}$$

Cyclic Processes

72 •• A 1.00-mol sample of N_2 gas at 20.0ºC and 5.00 atm is allowed to expand adiabatically and quasi-statically until its pressure equals 1.00 atm. It is then heated at constant pressure until its temperature is again 20.0ºC. After it reaches a temperature of 20.0ºC, it is heated at constant volume until its pressure is again 5.00 atm. It is then compressed at constant pressure until it is back to its original state. (*a*) Construct a *PV* diagram showing each process in the cycle. (*b*) From your graph, determine the work done by the gas during the complete cycle. (*c*) How much heat is absorbed (or released) by the gas during the complete cycle?

Picture the Problem To construct the *PV* diagram we'll need to determine the volume occupied by the gas at the beginning and ending points for each process. Let these points be A, B, C, and D. We can apply the ideal-gas law to the starting point (A) to find V_A. To find the volume at point B, we can use the relationship between pressure and volume for a quasi-static adiabatic process. We can use the ideal-gas law to find the volume at point C and, because they are equal, the volume at point D. We can apply the first law of thermodynamics to find the amount of heat added to or subtracted from the gas during the complete cycle.

(*a*) Using the ideal-gas law, express the volume of the gas at the starting point A of the cycle:

$$V_A = \frac{nRT_A}{P_A}$$

Substitute numerical values and evaluate V_A:

$$V_A = \frac{(1.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(293\,\text{K})}{5.00\,\text{atm}\times\frac{101.325\,\text{kPa}}{\text{atm}}} = 4.808\times10^{-3}\,\text{m}^3 = 4.808\,\text{L}$$

Use the relationship between pressure and volume for a quasi-static adiabatic process to express the volume of the gas at point B; the end point of the adiabatic expansion:

$$V_B = V_A\left(\frac{P_A}{P_B}\right)^{\frac{1}{\gamma}}$$

Substitute numerical values and evaluate V_B:

$$V_B = (4.808\,\text{L})\left(\frac{5.00\,\text{atm}}{1.00\,\text{atm}}\right)^{\frac{1}{1.4}} = 15.18\,\text{L}$$

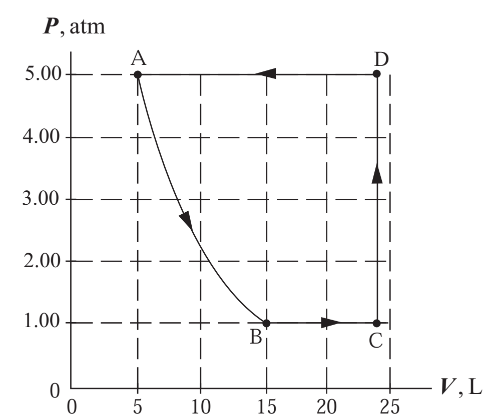
Using the ideal-gas law for a fixed amount of gas, express the volume occupied by the gas at points C and D:

$$V_C = V_D = \frac{nRT_C}{P_C}$$

Substitute numerical values and evaluate V_C:

$$V_C = \frac{(1.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(293\,\text{K})}{1.00\,\text{atm}\times\frac{101.325\,\text{kPa}}{\text{atm}}} = 24.04\times10^{-3}\,\text{m}^3 = 24.0\,\text{L}$$

The complete cycle is shown in the diagram.



(*b*) Note that for the paths A→B and B→C, $W_{\text{by gas}}$, the work done by the gas, is positive. For the path D→A, $W_{\text{by gas}}$ is negative, and greater in magnitude than $W_{A\to C}$. Therefore the total work done by the gas is negative. Find the area enclosed by the cycle by noting that each rectangle of dotted lines equals 5 atm·L and counting the rectangles:

$$W_{\text{by gas}} \approx -(13\,\text{rectangles})\left(5.00\frac{\text{atm}\cdot\text{L}}{\text{rectangle}}\right) = (-65\,\text{atm}\cdot\text{L})\left(\frac{101.325\,\text{J}}{\text{atm}\cdot\text{L}}\right)$$
$$= -6.586\,\text{kJ} = \boxed{-6.6\,\text{kJ}}$$

(*c*) The work done on the gas equals the negative of the work done by the gas. Apply the first law of thermodynamics to find the amount of heat added to or subtracted from the gas during the complete cycle:

$$Q_{\text{in}} = \Delta E_{\text{int}} - W_{\text{on}} = 0 - (-6.59\,\text{kJ})$$
$$= \boxed{6.6\,\text{kJ}}$$

because $\Delta E_{\text{int}} = 0$ for the complete cycle.

73 •• [SSM] A 1.00-mol sample of an ideal diatomic gas is allowed to expand. This expansion is represented by the straight line from 1 to 2 in the *PV* diagram (Figure 18-23). The gas is then compressed isothermally. This compression is represented by the straight line from 2 to 1 in the *PV* diagram. Calculate the work per cycle done by the gas.

Picture the Problem The total work done as the gas is taken through this cycle is the area bounded by the two processes. Because the process from 1→2 is linear, we can use the formula for the area of a trapezoid to find the work done during this expansion. We can use $W_{\text{isothermal process}} = nRT\ln(V_f/V_i)$ to find the work done on the gas during the process 2→1. The net work done during this cycle is then the sum of these two terms.

Express the net work done per cycle:

$$W_{\text{net}} = W_{\text{by the gas}} + W_{\text{on the gas}} = W_{1\to2} + W_{2\to1} \quad (1)$$

Work is done by the gas during its expansion from 1 to 2 and hence is equal to the negative of the area of the trapezoid defined by this path and the vertical lines at $V_1 = 11.5$ L and $V_2 = 23$ L. Use the formula for the area of a trapezoid to express $W_{1\to2}$:

$$W_{1\to2} = -A_{\text{trap}}$$
$$= -\tfrac{1}{2}(23\,\text{L} - 11.5\,\text{L}) \times (2.0\,\text{atm} + 1.0\,\text{atm})$$
$$= -17.3\,\text{L}\cdot\text{atm}$$

Work is done on the gas during the isothermal compression from V_2 to V_1 and hence is equal to the area under the curve representing this process. Use the expression for the work done during an isothermal process to express $W_{2\to1}$:

$$W_{2\to1} = nRT\ln\left(\frac{V_\text{f}}{V_\text{i}}\right)$$

Apply the ideal-gas law at point 1 to find the temperature along the isotherm 2→1:

$$T = \frac{PV}{nR} = \frac{(2.0\,\text{atm})(11.5\,\text{L})}{(1.00\,\text{mol})(8.206\times10^{-2}\,\text{L}\cdot\text{atm/mol}\cdot\text{K})} = 280\,\text{K}$$

Substitute numerical values and evaluate $W_{2\to1}$:

$$W_{2\to1} = \left|(1.00\,\text{mol})(8.206\times10^{-2}\,\text{L}\cdot\text{atm/mol}\cdot\text{K})(280\,\text{K})\ln\left(\frac{11.5\,\text{L}}{23\,\text{L}}\right)\right| = 15.9\,\text{L}\cdot\text{atm}$$

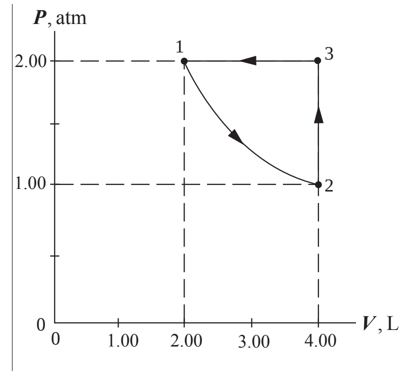
Substitute in equation (1) and evaluate W_net:

$$\begin{aligned} W_\text{net} &= -17.3\,\text{L}\cdot\text{atm} + 15.9\,\text{L}\cdot\text{atm} \\ &= -1.40\,\text{L}\cdot\text{atm}\times\frac{101.325\,\text{J}}{\text{L}\cdot\text{atm}} \\ &= \boxed{-0.14\,\text{kJ}} \end{aligned}$$

74 •• A 2.00-mol sample of an ideal monatomic gas has an initial pressure of 2.00 atm and an initial volume of 2.00 L. The gas is taken through the following quasi-static cycle: It is expanded isothermally until it has a volume of 4.00 L. It is next heated at constant volume until it has a pressure of 2.00 atm. It is then cooled at constant pressure until it is back to its initial state. (*a*) Show this cycle on a *PV* diagram. (*b*) Find the temperatures at the end of each part of the cycle. (*c*) Calculate the heat absorbed and the work done by the gas during each part of the cycle.

Picture the Problem Denote the initial and final points of each part of the cycle by the numerals 1, 2 and 3. We can apply the ideal-gas law to find the temperatures T_1, T_2, and T_3. We can use the appropriate work and heat equations to calculate the heat added and the work done by the gas for the isothermal process (1→2), the constant-volume process (2→3), and the isobaric process (3→1).

(*a*) The cycle is shown in the PV diagram to the right:



(*b*) Use the ideal-gas law to find T_1:

$$T_1 = \frac{P_1 V_1}{nR} = \frac{(2.00\,\text{atm})(2.00\,\text{L})}{(2.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 24.37\ \text{K} = \boxed{24.4\,\text{K}}$$

Because the process 1→2 is isothermal:

$$T_2 = \boxed{24.4\,\text{K}}$$

Use the ideal-gas law to find T_3:

$$T_3 = \frac{P_3 V_3}{nR} = \frac{(2.00\,\text{atm})(4.00\,\text{L})}{(2.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 48.74\ \text{K} = \boxed{48.7\,\text{K}}$$

(*c*) Because the process 1→2 is isothermal, $Q_{\text{in},1\to2} = W_{\text{by gas},1\to2}$:

$$Q_{\text{in},1\to2} = W_{\text{by gas},1\to2} = nRT\ln\left(\frac{V_2}{V_1}\right)$$

Substitute numerical values and evaluate $Q_{\text{in},1\to2}$:

$$Q_{\text{in},1\to2} = (2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(24.37\,\text{K})\ln\left(\frac{4.00\,\text{L}}{2.00\,\text{L}}\right) = \boxed{281\,\text{J}}$$

Because process 2→3 takes place at constant volume:

$$W_{2\to3} = \boxed{0}$$

Because process 2→3 takes place at constant volume, $W_{\text{on},2\to3} = 0$, and:

$$Q_{\text{in},2\to3} = \Delta E_{\text{int},2\to3} = C_\text{V}\Delta T = \tfrac{3}{2}nR(T_3 - T_2)$$

Substitute numerical values and evaluate $Q_{\text{in},2\to3}$:

$$Q_{\text{in},2\to3} = \tfrac{3}{2}(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(48.74\,\text{K} - 24.37\,\text{K}) = \boxed{608\,\text{J}}$$

Because process 3→1 is isobaric:

$$Q_{3\to1} = C_P\Delta T = \tfrac{5}{2}nR(T_1 - T_3)$$

Substitute numerical values and evaluate $Q_{3\to1}$:

$$Q_{3\to1} = \tfrac{5}{2}(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(24.37\,\text{K} - 48.74\,\text{K}) = \boxed{-1.01\,\text{kJ}}$$

The work done by the gas from 3 to 1 equals the negative of the work done on the gas:

$$W_{\text{by gas},3\to1} = -P_{1,3}\Delta V = P_{1,3}(V_1 - V_3)$$

Substitute numerical values and evaluate $W_{\text{by gas},3\to2}$:

$$W_{\text{by gas},3\to1} = -(2.00\,\text{atm})(2.00\,\text{L} - 4.00\,\text{L}) = -(-4.00\,\text{atm}\cdot\text{L})\left(\frac{101.325\,\text{J}}{\text{atm}\cdot\text{L}}\right)$$

$$= \boxed{405\,\text{J}}$$

75 ••• [SSM] At point D in Figure 18-24 the pressure and temperature of 2.00 mol of an ideal monatomic gas are 2.00 atm and 360 K, respectively. The volume of the gas at point B on the *PV* diagram is three times that at point D and its pressure is twice that at point C. Paths AB and CD represent isothermal processes. The gas is carried through a complete cycle along the path DABCD. Determine the total amount of work done by the gas and the heat absorbed by the gas along each portion of the cycle.

Picture the Problem We can find the temperatures, pressures, and volumes at all points for this ideal monatomic gas (3 degrees of freedom) using the ideal-gas law and the work for each process by finding the areas under each curve. We can find the heat exchanged for each process from the heat capacities and the initial and final temperatures for each process.

Express the total work done by the gas per cycle:

$$W_{\text{by gas,tot}} = W_{\text{D}\to\text{A}} + W_{\text{A}\to\text{B}} + W_{\text{B}\to\text{C}} + W_{\text{C}\to\text{D}}$$

1. Use the ideal-gas law to find the volume of the gas at point D:

$$V_D = \frac{nRT_D}{P_D} = \frac{(2.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(360\,\text{K})}{(2.00\,\text{atm})\left(101.325\,\frac{\text{kPa}}{\text{atm}}\right)} = 29.54\,\text{L}$$

2. We're given that the volume of the gas at point B is three times that at point D:

$$V_B = V_C = 3V_D = 3(29.54\,\text{L}) = 88.62\,\text{L}$$

Use the ideal-gas law to find the pressure of the gas at point C:

$$P_C = \frac{nRT_C}{V_C} = \frac{(2.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(360\,\text{K})}{88.62\,\text{L}} = 0.6667\,\text{atm}$$

We're given that the pressure at point B is twice that at point C:

$$P_B = 2P_C = 2(0.6667\,\text{atm}) = 1.333\,\text{atm}$$

3. Because path DC represents an isothermal process:

$$T_D = T_C = 360\,\text{K}$$

Use the ideal-gas law to find the temperatures at points B and A:

$$T_A = T_B = \frac{P_B V_B}{nR} = \frac{(1.333\,\text{atm})(88.62\,\text{L})}{(2.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 719.8\,\text{K}$$

Because the temperature at point A is twice that at D and the volumes are the same, we can conclude that:

$$\boldsymbol{P}_A = 2\boldsymbol{P}_D = 4.00\,\text{atm}$$

The pressure, volume, and temperature at points A, B, C, and D are summarized in the table to the right.

Point	P	V	T
	(atm)	(L)	(K)
A	4.00	29.5	720
B	1.33	88.6	720
C	0.667	88.6	360
D	2.00	29.5	360

4. For the path D→A, $W_{D\to A} = 0$ and:

$$Q_{D\to A} = \Delta E_{\text{int, D}\to\text{A}} = \tfrac{3}{2}nR\Delta T_{D\to A} = \tfrac{3}{2}nR(T_A - T_D)$$

Substitute numerical values and evaluate $Q_{D\to A}$:

$$Q_{D\to A} = \tfrac{3}{2}(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(720\,\text{K} - 360\,\text{K}) = 8.979\,\text{kJ}$$

For the path A→B:

$$W_{A\to B} = Q_{A\to B} = nRT_{A,B}\ln\left(\frac{V_B}{V_A}\right)$$

Substitute numerical values and evaluate $W_{A\to B}$:

$$W_{A\to B} = (2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(720\,\text{K})\ln\left(\frac{88.62\,\text{L}}{29.54\,\text{L}}\right) = 13.15\,\text{kJ}$$

and, because process A→B is isothermal, $\Delta E_{\text{int, A}\to\text{B}} = 0$

For the path B→C, $W_{B\to C} = 0$, and:

$$Q_{B\to C} = \Delta U_{B\to C} = C_V\Delta T = \tfrac{3}{2}nR(T_C - T_B)$$

Substitute numerical values and evaluate $Q_{B\to C}$:

$$Q_{B\to C} = \tfrac{3}{2}(2.00\,\text{mol})(8.314\,\text{J/mol}\cdot\text{K})(360\,\text{K} - 720\,\text{K}) = -8.979\,\text{kJ}$$

For the path C→D:

$$W_{C\to D} = nRT_{C,D}\ln\left(\frac{V_D}{V_C}\right)$$

Substitute numerical values and evaluate $W_{C\to D}$:

$$W_{C\to D} = (2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(360\,\text{K})\ln\left(\frac{29.54\,\text{L}}{88.62\,\text{L}}\right) = -6.576\,\text{kJ}$$

Also, because process A→B is isothermal, $\Delta E_{\text{int,A}\to\text{B}} = 0$, and $Q_{C\to D} = W_{C\to D} = -6.58\,\text{kJ}$

Q_{in}, W_{on}, and ΔE_{int} are summarized for each of the processes in the table to the right.

Process	Q_{in}	W_{on}	ΔE_{int}
	(kJ)	(kJ)	(kJ)
D→A	$\boxed{8.98}$	0	8.98
A→B	$\boxed{13.2}$	−13.2	0
B→C	$\boxed{-8.98}$	0	−8.98
C→D	$\boxed{-6.58}$	6.58	0

Referring to the table, find the total work done by the gas per cycle:

$$\begin{aligned} W_{\text{by gas, tot}} &= W_{D\to A} + W_{A\to B} + W_{B\to C} + W_{C\to D} \\ &= 0 + 13.2\,\text{kJ} + 0 - 6.58\,\text{kJ} \\ &= \boxed{6.6\,\text{kJ}} \end{aligned}$$

Remarks: Note that, as it should be, ΔE_{int} is zero for the complete cycle.

76 ••• At point D in Figure 18-24 the pressure and temperature of 2.00 mol of an ideal diatomic gas are 2.00 atm and 360 K, respectively. The volume of the gas at point B on the *PV* diagram is three times that at point D and its pressure is twice that at point C. Paths AB and CD represent isothermal processes. The gas is carried through a complete cycle along the path DABCD. Determine the total amount of work done by the gas and the heat absorbed by the gas along each portion of the cycle.

Picture the Problem We can find the temperatures, pressures, and volumes at all points for this ideal diatomic gas (5 degrees of freedom) using the ideal-gas law and the work for each process by finding the areas under each curve. We can find the heat exchanged for each process from the heat capacities and the initial and final temperatures for each process.

Express the total work done by the gas per cycle:

$$W_{\text{by gas,tot}} = W_{\text{D}\to\text{A}} + W_{\text{A}\to\text{B}} + W_{\text{B}\to\text{C}} + W_{\text{C}\to\text{D}}$$

1. Use the ideal-gas law to find the volume of the gas at point D:

$$V_{\text{D}} = \frac{nRT_{\text{D}}}{P_{\text{D}}} = \frac{(2.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(360\,\text{K})}{(2.00\,\text{atm})\left(101.325\,\frac{\text{kPa}}{\text{atm}}\right)} = 29.54\,\text{L}$$

2. We're given that the volume of the gas at point B is three times that at point D:

$$V_{\text{B}} = V_{\text{C}} = 3V_{\text{D}} = 3(29.54\,\text{L}) = 88.62\,\text{L}$$

Use the ideal-gas law to find the pressure of the gas at point C:

$$P_{\text{C}} = \frac{nRT_{\text{C}}}{V_{\text{C}}} = \frac{(2.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(360\,\text{K})}{88.62\,\text{L}} = 0.6667\,\text{atm}$$

We're given that the pressure at point B is twice that at point C:

$$P_{\text{B}} = 2P_{\text{C}} = 2(0.6667\,\text{atm}) = 1.333\,\text{atm}$$

3. Because path DC represents an isothermal process:

$$T_{\text{D}} = T_{\text{C}} = 360\,\text{K}$$

Use the ideal-gas law to find the temperatures at points B and A:

$$T_{\text{A}} = T_{\text{B}} = \frac{P_{\text{B}}V_{\text{B}}}{nR} = \frac{(1.333\,\text{atm})(88.62\,\text{L})}{(2.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 719.8\,\text{K}$$

Because the temperature at point A is twice that at D and the volumes are the same, we can conclude that:

$$P_{\text{A}} = 2P_{\text{D}} = 4.00\,\text{atm}$$

The pressure, volume, and temperature at points A, B, C, and D are summarized in the table to the right.

Point	P	V	T
	(atm)	(L)	(K)
A	4.00	29.5	720
B	1.33	88.6	720
C	0.667	88.6	360
D	2.00	29.5	360

4. For the path D→A, $W_{\mathrm{D}\to\mathrm{A}} = 0$ and:

$$\begin{aligned} Q_{\mathrm{D}\to\mathrm{A}} &= \Delta U_{\mathrm{D}\to\mathrm{A}} = \tfrac{5}{2}nR\Delta T_{\mathrm{D}\to\mathrm{A}} = \tfrac{5}{2}nR(T_\mathrm{A} - T_\mathrm{D}) \\ &= \tfrac{5}{2}(2.00\,\mathrm{mol})\left(8.314\frac{\mathrm{J}}{\mathrm{mol\cdot K}}\right)(720\,\mathrm{K} - 360\,\mathrm{K}) \\ &= 14.97\,\mathrm{kJ} \end{aligned}$$

For the path A→B:

$$W_{\mathrm{A}\to\mathrm{B}} = Q_{\mathrm{A}\to\mathrm{B}} = nRT_{\mathrm{A,B}}\ln\left(\frac{V_\mathrm{B}}{V_\mathrm{A}}\right) = (2.00\,\mathrm{mol})\left(8.314\frac{\mathrm{J}}{\mathrm{mol\cdot K}}\right)(720\,\mathrm{K})\ln\left(\frac{88.62\,\mathrm{L}}{29.54\,\mathrm{L}}\right)$$
$$= 13.15\,\mathrm{kJ}$$

and, because process A→B is isothermal, $\Delta E_{\mathrm{int,A}\to\mathrm{B}} = 0$

For the path B→C, $W_{\mathrm{B}\to\mathrm{C}} = 0$ and:

$$\begin{aligned} Q_{\mathrm{B}\to\mathrm{C}} &= \Delta U_{\mathrm{B}\to\mathrm{C}} = C_\mathrm{V}\Delta T = \tfrac{5}{2}nR(T_\mathrm{C} - T_\mathrm{B}) \\ &= \tfrac{5}{2}(2.00\,\mathrm{mol})\left(8.314\frac{\mathrm{J}}{\mathrm{mol\cdot K}}\right)(360\,\mathrm{K} - 720\,\mathrm{K}) \\ &= -14.97\,\mathrm{kJ} \end{aligned}$$

For the path C→D:

$$W_{\mathrm{C}\to\mathrm{D}} = nRT_{\mathrm{C,D}}\ln\left(\frac{V_\mathrm{D}}{V_\mathrm{C}}\right) = (2.00\,\mathrm{mol})\left(8.314\frac{\mathrm{J}}{\mathrm{mol\cdot K}}\right)(360\,\mathrm{K})\ln\left(\frac{29.54\,\mathrm{L}}{88.62\,\mathrm{L}}\right) = -6.576\,\mathrm{kJ}$$

Also, because process A→B is isothermal, $\Delta E_{\mathrm{int,A}\to\mathrm{B}} = 0$ and
$Q_{\mathrm{C}\to\mathrm{D}} = W_{\mathrm{C}\to\mathrm{D}} = -6.576\,\mathrm{kJ}$

Q_{in}, W_{on}, and ΔE_{int} are summarized for each of the processes in the table to the right.

Process	Q_{in}	W_{on}	ΔE_{int}
	(kJ)	(kJ)	(kJ)
D→A	$\boxed{15.0}$	0	15.0
A→B	$\boxed{13.2}$	−13.2	0
B→C	$\boxed{-15.0}$	0	−15.0
C→D	$\boxed{-6.58}$	6.58	0

Referring to the table and noting that the work done by the gas equals the negative of the work done on the gas, find the total work done by the gas per cycle:

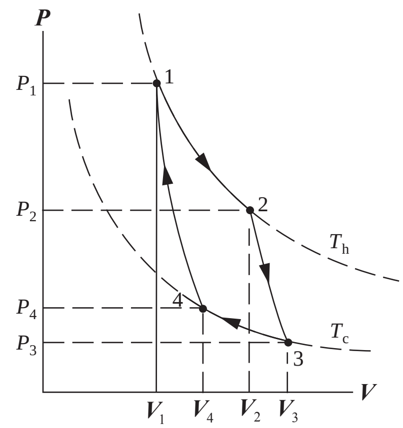
$$W_{\text{by gas,tot}} = W_{\text{D}\to\text{A}} + W_{\text{A}\to\text{B}} + W_{\text{B}\to\text{C}} + W_{\text{C}\to\text{D}} = 0 + 13.2\,\text{kJ} + 0 - 6.58\,\text{kJ} = \boxed{6.6\,\text{kJ}}$$

Remarks: Note that ΔE_{int} for the complete cycle is zero and that the total work done is the same for the diatomic gas of this problem and the monatomic gas of problem 75.

77 ••• A sample consisting of n moles of an ideal gas is initially at pressure P_1, volume V_1, and temperature T_h. It expands isothermally until its pressure and volume are P_2 and V_2. It then expands adiabatically until its temperature is T_c and its pressure and volume are P_3 and V_3. It is then compressed isothermally until it is at a pressure P_4 and a volume V_4, which is related to its initial volume V_1 by $T_c V_4^{\gamma-1} = T_h V_1^{\gamma-1}$. The gas is then compressed adiabatically until it is back in its original state. (*a*) Assuming that each process is quasi-static, plot this cycle on a PV diagram. (This cycle is known as the Carnot cycle for an ideal gas.) (*b*) Show that the heat Q_h absorbed during the isothermal expansion at T_h is $Q_h = nRT_h \ln(V_2/V_1)$. (*c*) Show that the heat Q_c released by the gas during the isothermal compression at T_c is $Q_c = nRT_c \ln(V_3/V_4)$. (*d*) Using the result that $TV^{\gamma-1}$ is constant for a quasi-static adiabatic expansion, show that $V_2/V_1 = V_3/V_4$. (*e*) The efficiency of a Carnot cycle is defined as the net work done by the gas, divided by the heat absorbed Q_h by the gas. Using the first law of thermodynamics, show that the efficiency is $1 - Q_c/Q_h$. (*f*) Using your results from the previous parts of this problem, show that $Q_c/Q_h = T_c/T_h$.

Picture the Problem We can use the equations of state for adiabatic and isothermal processes to express the work done on or by the system, the heat entering or leaving the system, and the change in internal energy for each of the four processes making up the Carnot cycle. We can use the first law of thermodynamics and the definition of the efficiency of a Carnot cycle to show that the efficiency is $1 - Q_c / Q_h$.

(*a*) The cycle is shown on the *PV* diagram to the right:



(*b*) Because the process 1→2 is isothermal:

$$\Delta E_{\text{int},1\to2} = 0$$

Apply the first law of thermodynamics to obtain:

$$Q_h = Q_{1\to2} = W_{1\to2} = \boxed{nRT_h \ln\left(\frac{V_2}{V_1}\right)}$$

(*c*) Because the process 3→4 is isothermal:

$$\Delta U_{3\to4} = 0$$

Apply the first law of thermodynamics to obtain:

$$Q_c = Q_{3\to4} = W_{3\to4} = nRT_c \ln\left(\frac{V_4}{V_3}\right)$$

$$= \boxed{-nRT_c \ln\left(\frac{V_3}{V_4}\right)}$$

where the minus sign tells us that heat is given off by the gas during this process.

(*d*) Apply the equation for a quasi-static adiabatic process at points 4 and 1 to obtain:

$$T_c V_4^{\gamma-1} = T_h V_1^{\gamma-1} \Rightarrow \frac{V_1}{V_4} = \left(\frac{T_c}{T_h}\right)^{\frac{1}{\gamma-1}} \quad (1)$$

Apply the equation for a quasi-static adiabatic process at points 2 and 3 to obtain:

$$T_h V_2^{\gamma-1} = T_c V_3^{\gamma-1} \Rightarrow \frac{V_2}{V_3} = \left(\frac{T_c}{T_h}\right)^{\frac{1}{\gamma-1}} \quad (2)$$

Equate equations (1) and (2) and rearrange to obtain:

$$\frac{V_3}{V_4} = \boxed{\frac{V_2}{V_1}}$$

(*e*) Express the efficiency of the Carnot cycle:

$$\varepsilon = \frac{W}{Q_h}$$

Apply the first law of thermodynamics to obtain:

$$W_{on} = \Delta E_{int,\,cycle} - Q_{in}$$
$$= 0 - (Q_h - Q_c) = -(Q_h - Q_c)$$

because E_{int} is a state function and $\Delta E_{int,\,cycle} = 0$.

Substitute to obtain:

$$\varepsilon = \frac{W_{\text{by the gas}}}{Q_h} = \frac{-W_{on}}{Q_h} = \frac{Q_h - Q_c}{Q_h}$$
$$= \boxed{1 - \frac{Q_c}{Q_h}}$$

(*f*) In Part (*b*) we established that:

$$Q_h = nRT_h \ln\left(\frac{V_2}{V_1}\right)$$

In Part (*c*) we established that the heat leaving the system along the path 3→4 is given by:

$$Q_c = nRT_c \ln\left(\frac{V_3}{V_4}\right)$$

Divide the second of these equations by the first to obtain:

$$\frac{Q_c}{Q_h} = \frac{nRT_c \ln\left(\frac{V_3}{V_4}\right)}{nRT_h \ln\left(\frac{V_2}{V_1}\right)} = \boxed{\frac{T_c}{T_h}}$$

because $\frac{V_3}{V_4} = \frac{V_2}{V_1}$.

Remarks: This last result establishes that the efficiency of a Carnot cycle is also given by $\varepsilon_C = 1 - \frac{T_c}{T_h}$.

General Problems

78 • During the process of quasi-statically compressing an ideal diatomic gas to one-fifth of its initial volume, 180 kJ of work are done on the gas. (*a*) If this compression is accomplished isothermally at room temperature (293 K), how much heat is released by the gas? (*b*) How many moles of gas are in this sample?

Picture the Problem (*a*) We can use the first law of thermodynamics to relate the heat removed from the gas to the work done on the gas. (*b*) We can find the number of moles of the gas from the expression for the work done on or by a gas during an isothermal process.

(*a*) Apply the first law of thermodynamics to this process:

$$Q_{\text{in}} = \Delta E_{\text{int}} - W_{\text{on}} = -W_{\text{on}}$$

because $\Delta E_{\text{int}} = 0$ for an isothermal process.

Substitute numerical values to obtain:

$$Q_{\text{in}} = -180\,\text{kJ}$$

Because $Q_{\text{removed}} = -Q_{\text{in}}$:

$$Q_{\text{removed}} = \boxed{180\,\text{kJ}}$$

(*b*) The work done on the gas during the isothermal process is given by:

$$W = nRT\ln\left(\frac{V_{\text{f}}}{V_{\text{i}}}\right) \Rightarrow n = \frac{W}{RT\ln\left(\frac{V_{\text{f}}}{V_{\text{i}}}\right)}$$

Substitute numerical values and evaluate *n*:

$$n = \frac{-180\,\text{kJ}}{\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(293\,\text{K})\ln\left(\frac{1}{5}\right)} = \boxed{45.9\,\text{mol}}$$

79 • **[SSM]** The *PV* diagram in Figure 18-25 represents 3.00 mol of an ideal monatomic gas. The gas is initially at point A. The paths AD and BC represent isothermal changes. If the system is brought to point C along the path AEC, find (*a*) the initial and final temperatures of the gas, (*b*) the work done by the gas, and (*c*) the heat absorbed by the gas.

Picture the Problem We can use the ideal-gas law to find the temperatures T_{A} and T_{C}. Because the process EDC is isobaric, we can find the area under this line geometrically and then use the 1st law of thermodynamics to find Q_{AEC}.

(*a*) Using the ideal-gas law, find the temperature at point A:

$$T_A = \frac{P_A V_A}{nR} = \frac{(4.0\,\text{atm})(4.01\,\text{L})}{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 65.2\,\text{K} = \boxed{65\,\text{K}}$$

Using the ideal-gas law, find the temperature at point C:

$$T_C = \frac{P_C V_C}{nR} = \frac{(1.0\,\text{atm})(20.0\,\text{L})}{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 81.2\,\text{K} = \boxed{81\,\text{K}}$$

(*b*) Express the work done by the gas along the path AEC:

$$\begin{aligned} W_{AEC} &= W_{AE} + W_{EC} = 0 + P_{EC}\Delta V_{EC} \\ &= (1.0\,\text{atm})(20.0\,\text{L} - 4.01\,\text{L}) \\ &= 15.99\,\text{L}\cdot\text{atm}\times\frac{101.325\,\text{J}}{\text{L}\cdot\text{atm}} \\ &= 1.62\,\text{kJ} = \boxed{1.6\,\text{kJ}} \end{aligned}$$

(*c*) Apply the first law of thermodynamics to express Q_{AEC}:

$$\begin{aligned} Q_{AEC} &= W_{AEC} + \Delta E_{int} = W_{AEC} + C_V\Delta T \\ &= W_{AEC} + \tfrac{3}{2}nR\Delta T \\ &= W_{AEC} + \tfrac{3}{2}nR(T_C - T_A) \end{aligned}$$

Substitute numerical values and evaluate Q_{AEC}:

$$Q_{AEC} = 1.62\,\text{kJ} + \tfrac{3}{2}(3.00\,\text{mol})(8.314\,\text{J/mol}\cdot\text{K})(81.2\,\text{K} - 65.2\,\text{K}) = \boxed{2.2\,\text{kJ}}$$

Remarks The difference between W_{AEC} and Q_{AEC} is the change in the internal energy $\Delta E_{int,AEC}$ during this process.

80 •• The *PV* diagram in Figure 18-25 represents 3.00 mol of an ideal monatomic gas. The gas is initially at point A. The paths AD and BC represent isothermal changes. If the system is brought to point C along the path ABC, find (*a*) the initial and final temperatures of the gas, (*b*) the work done by the gas, and (*c*) the heat absorbed by the gas.

Picture the Problem We can use the ideal-gas law to find the temperatures T_A and T_C. Because the process AB is isobaric, we can find the area under this line

geometrically. We can use the expression for the work done during an isothermal expansion to find the work done between B and C and the first law of thermodynamics to find Q_{ABC}.

(*a*) Using the ideal-gas law, find the temperature at point A:

$$T_A = \frac{P_A V_A}{nR} = \frac{(4.0\,\text{atm})(4.01\,\text{L})}{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 65.2\,\text{K} = \boxed{65\,\text{K}}$$

Use the ideal-gas law to find the temperature at point C:

$$T_C = \frac{P_C V_C}{nR} = \frac{(1.0\,\text{atm})(20.0\,\text{L})}{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 81.2\,\text{K} = \boxed{81\,\text{K}}$$

(*b*) Express the work done by the gas along the path ABC:

$$W_{ABC} = W_{AB} + W_{BC} = P_{AB}\Delta V_{AB} + nRT_B \ln\left(\frac{V_C}{V_B}\right)$$

Use the ideal-gas law to find the volume of the gas at point B:

$$V_B = \frac{nRT_B}{P_B} = \frac{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(81.2\,\text{K})}{4.0\,\text{atm}} = 5.00\,\text{L}$$

Substitute numerical values and evaluate W_{ABC}:

$$W_{ABC} = (4.0\,\text{atm})(5.00\,\text{L} - 4.01\,\text{L}) + (3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right) \times (81.2\,\text{K})\ln\left(\frac{20.0\,\text{L}}{5.00\,\text{L}}\right)$$

$$= 31.7\,\text{L}\cdot\text{atm}\times\frac{101.325\,\text{J}}{\text{atm}} = 3.21\,\text{kJ} = \boxed{3.2\,\text{kJ}}$$

(*c*) Apply the first law of thermodynamics to obtain:

$$\begin{aligned} Q_{\text{ABC}} &= W_{\text{ABC}} + \Delta E_{\text{int}} = W_{\text{ABC}} + C_{\text{V}}\Delta T \\ &= W_{\text{ABC}} + \tfrac{3}{2}nR\Delta T \\ &= W_{\text{ABC}} + \tfrac{3}{2}nR\left(T_{\text{C}} - T_{A}\right) \end{aligned}$$

Substitute numerical values and evaluate Q_{ABC}:

$$Q_{\text{ABC}} = 3.21\,\text{kJ} + \tfrac{3}{2}(3.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(81.2\,\text{K} - 65.2\,\text{K}) = \boxed{3.8\,\text{kJ}}$$

Remarks: The difference between W_{ABC} and Q_{ABC} is the change in the internal energy $\Delta E_{\text{int,ABC}}$ during this process.

81 •• The *PV* diagram in Figure 18-25 represents 3.00 mol of an ideal monatomic gas. The gas is initially at point A. The paths AD and BC represent isothermal changes. If the system is brought to point C along the path ADC, find (*a*) the initial and final temperatures of the gas, (*b*) the work done by the gas, and (*c*) the heat absorbed by the gas.

Picture the Problem We can use the ideal-gas law to find the temperatures T_{A} and T_{C}. Because the process DC is isobaric, we can find the area under this line geometrically. We can use the expression for the work done during an isothermal expansion to find the work done between A and D and the first law of thermodynamics to find Q_{ADC}.

(*a*) Using the ideal-gas law, find the temperature at point A:

$$\begin{aligned} T_{\text{A}} &= \frac{P_{\text{A}}V_{\text{A}}}{nR} \\ &= \frac{(4.0\,\text{atm})(4.01\,\text{L})}{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} \\ &= 65.2\,\text{K} = \boxed{65\,\text{K}} \end{aligned}$$

Use the ideal-gas law to find the temperature at point C:

$$\begin{aligned} T_{\text{C}} &= \frac{P_{\text{C}}V_{\text{C}}}{nR} \\ &= \frac{(1.0\,\text{atm})(20\,\text{L})}{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} \\ &= \boxed{81\,\text{K}} \end{aligned}$$

(*b*) Express the work done by the gas along the path ADC:

$$W_{ADC} = W_{AD} + W_{DC} = nRT_A \ln\left(\frac{V_D}{V_A}\right) + P_{DC}\Delta V_{DC}$$

Use the ideal-gas law to find the volume of the gas at point D:

$$V_D = \frac{nRT_D}{P_D} = \frac{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(65.2\,\text{K})}{1.0\,\text{atm}} = 16.051\,\text{L}$$

Substitute numerical values and evaluate W_{ADC}:

$$\begin{aligned} W_{ADC} &= (3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(65.2\,\text{K})\ln\left(\frac{16.1\,\text{L}}{4.01\,\text{L}}\right) \\ &\quad + (1.0\,\text{atm})(20.0\,\text{L} - 16.1\,\text{L}) \\ &= 26.2\,\text{L}\cdot\text{atm}\times\frac{101.325\,\text{J}}{\text{L}\cdot\text{atm}} = 2.65\,\text{kJ} = \boxed{2.7\,\text{kJ}} \end{aligned}$$

(*c*) Apply the first law of thermodynamics to obtain:

$$\begin{aligned} Q_{ADC} &= W_{ADC} + \Delta E_{int} = W_{ADC} + C_V\Delta T \\ &= W_{ADC} + \tfrac{3}{2}nR\Delta T \\ &= W_{ADC} + \tfrac{3}{2}nR(T_C - T_A) \end{aligned}$$

Substitute numerical values and evaluate Q_{ADC}:

$$Q_{ADC} = 2.65\,\text{kJ} + \tfrac{3}{2}(3.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(81.2\,\text{K} - 65.2\,\text{K}) = \boxed{3.3\,\text{kJ}}$$

82 •• Suppose that the paths AD and BC in Figure 18-25 represent adiabatic processes. What are the work done by the gas and the heat absorbed by the gas in following the path ABC?

Picture the Problem We can use the ideal-gas law to find the temperatures T_A and T_C. Because the process AB is isobaric, we can find the area under this line geometrically. We can find the work done during the adiabatic expansion between B and C using $W_{BC} = -C_V\Delta T_{BC}$ and the first law of thermodynamics to find Q_{ABC}.

The work done by the gas along path ABC is given by:

$$W_{ABC} = W_{AB} + W_{BC}$$
$$= P_{AB}\Delta V_{AB} - C_V\Delta T_{BC}$$
$$= P_{AB}\Delta V_{AB} - \tfrac{3}{2}nR\Delta T_{BC}$$

because, with $Q_{in} = 0$, $W_{BC} = -\Delta E_{int,BC}$.

Use the ideal-gas law to find T_A:

$$T_A = \frac{P_A V_A}{nR} = \frac{(4.0\,\text{atm})(4.01\,\text{L})}{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 65.2\,\text{K}$$

Use the ideal-gas law to express T_B:

$$T_B = \frac{P_B V_B}{nR}$$

Apply the pressure-volume relationship for a quasi-static adiabatic process to the gas at points B and C to find the volume of the gas at point B:

$$P_B V_B^\gamma = P_C V_C^\gamma$$

and

$$V_B = \left(\frac{P_C}{P_B}\right)^{\frac{1}{\gamma}} V_C = \left(\frac{1.0\,\text{atm}}{4.0\,\text{atm}}\right)^{\frac{3}{5}}(20.0\,\text{L}) = 8.71\,\text{L}$$

Substitute numerical values and evaluate T_B:

$$T_B = \frac{(4.0\,\text{atm})(8.71\,\text{L})}{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 142\,\text{K}$$

Use the ideal-gas law to express T_C:

$$T_C = \frac{P_C V_C}{nR}$$

Substitute numerical values and evaluate T_C:

$$T_C = \frac{(1.0\,\text{atm})(20.0\,\text{L})}{(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 81.2\,\text{K}$$

Substitute numerical values and evaluate W_{ABC}:

$$\begin{aligned} W_{\text{ABC}} &= (4.0\,\text{atm})(8.71\,\text{L} - 4.01\,\text{L}) - \tfrac{3}{2}(3.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right) \\ &\quad \times(81.2\,\text{K} - 142\,\text{K}) \\ &= 41.3\,\text{L}\cdot\text{atm}\times\frac{101.325\,\text{J}}{\text{atm}} = 4.18\,\text{kJ} = \boxed{4.2\,\text{kJ}} \end{aligned}$$

Apply the 1st law of thermodynamics to obtain:

$$\begin{aligned} Q_{\text{ABC}} &= W_{\text{ABC}} + \Delta E_{\text{int}} = W_{\text{ABC}} + C_{\text{V}}\Delta T \\ &= W_{\text{ABC}} + \tfrac{3}{2}nR\Delta T \\ &= W_{\text{ABC}} + \tfrac{3}{2}nR(T_{\text{C}} - T_{A}) \end{aligned}$$

Substitute numerical values and evaluate Q_{ABC}:

$$Q_{\text{ABC}} = 4.18\,\text{kJ} + \tfrac{3}{2}(3.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(81.2\,\text{K} - 65.2\,\text{K}) = \boxed{4.8\,\text{kJ}}$$

83 •• [SSM] As part of a laboratory experiment, you test the calorie content of various foods. Assume that when you eat these foods, 100% of the energy released by the foods is absorbed by your body. Suppose you burn a 2.50-g potato chip, and the resulting flame warms a small aluminum can of water. After burning the potato chip, you measure its mass to be 2.20 g. The mass of the can is 25.0 g, and the volume of water contained in the can is 15.0 ml. If the temperature increase in the water is 12.5°C, how many kilocalories (1 kcal = 1 dietary calorie) per 150-g serving of these potato chips would you estimate there are? Assume the can of water captures 50.0 percent of the heat released during the burning of the potato chip. *Note: Although the joule is the SI unit of choice in most thermodynamic situations, the food industry in the United States currently expresses the energy released during metabolism in terms of the "dietary calorie," which is our kilocalorie.*

Picture the Problem The ratio of the energy in a 150-g serving to the energy in 0.30 g of potato chip is the same as the ratio of the masses of the serving and the amount of the chip burned while heating the aluminum can and the water in it.

The ratio of the energy in a 150-g serving to the energy in 0.30 g of potato chip is the same as the ratio of the masses of the serving and the amount of the chip burned while heating the aluminum can and the water in it:

$$\frac{Q_{150\text{-g serving}}}{Q_{0.30\,\text{g}}}=\frac{150\text{ g}}{0.30\text{ g}}=500$$

or

$$Q_{150\text{ g serving}}=500Q_{0.30\,\text{g}}$$

Letting f represent the fraction of the heat captured by the can of water, express the energy transferred to the aluminum can and the water in it during the burning of the potato chip:

$$\begin{aligned}fQ_{0.30\,\text{g}}&=Q_{\text{Al}}+Q_{\text{H}_2\text{O}}\\&=m_{\text{Al}}c_{\text{Al}}\Delta T+m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\Delta T\\&=\left(m_{\text{Al}}c_{\text{Al}}+m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\right)\Delta T\end{aligned}$$

where ΔT is the common temperature change of the aluminum cup and the water it contains.

Substituting for $Q_{0.30\,\text{g}}$ yields and solving for $Q_{150\text{-g serving}}$ yields:

$$Q_{150\text{-g serving}}=\frac{500\left(m_{\text{Al}}c_{\text{Al}}+m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\right)\Delta T}{f}$$

Substitute numerical values and evaluate $Q_{150\text{-g serving}}$:

$$\begin{aligned}Q_{150\text{-g serving}}&=\frac{500\left[(0.0250\text{ kg})\left(0.900\dfrac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)+(0.0150\text{ kg})\left(4.184\dfrac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\right](12.5\text{ C}^\circ)}{0.500}\\&=1.07\times10^{6}\text{ J}\times\frac{1\text{ cal}}{4.184\text{ J}}=256\times10^{3}\text{ cal}\approx\boxed{256\text{ kcal}}\end{aligned}$$

84 •• Diesel engines operate without spark plugs, unlike gasoline engines. The cycle that diesel engines undergo involves adiabatically compressing the air in a cylinder, and then fuel is injected. When the fuel is injected, if the air temperature inside the cylinder is above the fuel's flashpoint, the fuel-air mixture will ignite. Most diesel engines have compression ratios in the range from 14:1 to 25:1. For this range of compression ratios (which are the ratio of maximum to minimum volume), what is the range of maximum temperatures of the air in the cylinder, assuming the air is taken into the cylinder at 35°C? Most modern gasoline engines typically have compression ratios on the order of 8:1. Explain why you expect the diesel engine to require a better (more efficient) cooling system than its gasoline counterpart.

Picture the Problem You can use the equation-of-state for an adiabatic process to find the range of maximum temperatures of the air in the cylinder.

For an adiabatic process from state i to state f:

$$T_i V_i^{\gamma-1} = T_f V_f^{\gamma-1}$$

where, for a diatomic gas, $\gamma = 1.4$.

Solving for T_f yields:

$$T_f = T_i \frac{V_i^{\gamma-1}}{V_f^{\gamma-1}} = T_i \left(\frac{V_i}{V_f}\right)^{\gamma-1}$$

Substitute numerical values and evaluate T_f for an engine with a compression ratio of 14:1:

$$T_f = (273\ \text{K} + 35\ \text{C°})\left(\frac{14}{1}\right)^{1.4-1}$$
$$= 885\ \text{K} = 612°\text{C}$$

Substitute numerical values and evaluate T_f for an engine with a compression ratio of 25:1:

$$T_f = (273\ \text{K} + 35\ \text{C°})\left(\frac{25}{1}\right)^{1.4-1}$$
$$= 1116\ \text{K} = 843°\text{C}$$

The range of maximum temperatures of the air in the cylinder, assuming it is taken into the cylinder at 35°C, is $\boxed{612°\text{C} \rightarrow 843°\text{C}}$.

Gasoline engines, with much lower compression ratios, would clearly have lower maximum operating temperatures and thus be subject to overall, average, lower temperatures and not require as extensive cooling systems.

85 •• At very low temperatures, the specific heat of a metal is given by $c = aT + bT^3$. For copper, $a = 0.0108$ J/kg·K^2 and $b = 7.62 \times 10^{-4}$ J/kg·K^4. (*a*) What is the specific heat of copper at 4.00 K? (*b*) How much heat is required to heat copper from 1.00 to 3.00 K?

Picture the Problem We can find c at $T = 4.00$ K by direct substitution. Because c is a function of T, we can integrate dQ over the given temperature interval in order to find the heat required to heat copper from 1.00 to 3.00 K.

(*a*) Substitute for *a* and *b* to obtain:

$$c = \left(0.0108 \frac{\text{J}}{\text{kg}\cdot\text{K}^2}\right)T + \left(7.62\times10^{-4}\frac{\text{J}}{\text{kg}\cdot\text{K}^4}\right)T^3$$

Evaluate c at $T = 4.00$ K:

$$c(4.00\,\text{K}) = \left(0.0108\frac{\text{J}}{\text{kg}\cdot\text{K}^2}\right)(4.00\,\text{K}) + \left(7.62\times10^{-4}\frac{\text{J}}{\text{kg}\cdot\text{K}^4}\right)(4.00\,\text{K})^3$$
$$= \boxed{9.20\times10^{-2}\frac{\text{J}}{\text{kg}\cdot\text{K}}}$$

(*b*) The heat required to heat copper from 1.00 to 3.00 K is given by:

$$Q = \int_{1.00\,\text{K}}^{3.00\,\text{K}} c(T)\,dT$$

Substituting for $c(T)$ yields:

$$Q = \left(0.0108\frac{\text{J}}{\text{kg}\cdot\text{K}^2}\right)\int_{1.00\,\text{K}}^{3.00\,\text{K}} T\,dT + \left(7.62\times10^{-4}\frac{\text{J}}{\text{kg}\cdot\text{K}^4}\right)\int_{1.00\,\text{K}}^{3.00\,\text{K}} T^3\,dT$$

Evaluate this integral to obtain:

$$Q = \left(0.0108\frac{\text{J}}{\text{kg}\cdot\text{K}^2}\right)\left[\frac{T^2}{2}\right]_{1.00\,\text{K}}^{3.00\,\text{K}} + \left(7.62\times10^{-4}\frac{\text{J}}{\text{kg}\cdot\text{K}^4}\right)\left[\frac{T^4}{4}\right]_{1.00\,\text{K}}^{3.00\,\text{K}} = \boxed{0.0584\,\text{J/kg}}$$

86 •• How much work must be done on 30.0 g of carbon monoxide (CO) at standard temperature and pressure to compress it to one-fifth of its initial volume if the process is (*a*) isothermal, (*b*) adiabatic?

Picture the Problem (*a*) Let the subscripts 1 and 2 refer to the initial and final state respectively. Because the gas is initially at standard temperature and pressure, we know that V_1 = 22.4 L/mol, P_1 = 1 atm, and T_1 = 273 K. We can use $W = -nRT\ln(V_2/V_1)$ to find the work done on the gas during an isothermal compression. (*b*) We can use $W_{\text{on}} = -nC_{\text{V}}(T_1 - T_2)$ to find the work done on the gas during the adiabatic compression. Note that γ = 1.4 for diatomic gasses and see Appendix C for the molar mass of CO.

(*a*) Express the work done on the gas in compressing it isothermally:

$$W_{\text{on}} = -nRT\ln\left(\frac{V_2}{V_1}\right)$$

Because the number of moles of CO is the mass m of CO divided by its molar mass:

$$W_{\text{on}} = -\frac{m}{M}RT\ln\left(\frac{V_2}{V_1}\right)$$

Substitute numerical values and evaluate W_{on}:

$$W_{\text{on}} = -\left(\frac{30.0\,\text{g}}{28.01\,\text{g/mol}}\right)\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(273\,\text{K})\ln\left(\frac{1}{5}\right) = \boxed{3.91\,\text{kJ}}$$

(*b*) Express the work done on the gas in compressing it adiabatically:

$$W_{\text{on}} = -nC_{\text{V}}(T_1 - T_2) = -\frac{m}{M}C_{\text{V}}(T_1 - T_2)$$

Using the equation for a quasi-static adiabatic process, relate the initial and final temperatures and volumes:

$$T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1} \Rightarrow T_2 = T_1\left(\frac{V_1}{V_2}\right)^{\gamma-1}$$

Substituting for T_2 and V_2 and simplifying gives:

$$W_{\text{on}} = -\frac{m}{M}C_{\text{V}}\left(T_1 - T_1\left(\frac{V_1}{\frac{1}{5}V_1}\right)^{\gamma-1}\right)$$

$$= -\frac{m}{M}C_{\text{V}}T_1\left(1-(5)^{\gamma-1}\right)$$

Because $C_{\text{V}} = 2.49R$ for an ideal diatomic gas (see Table 18-3):

$$W_{\text{on}} = -2.49\frac{m}{M}RT_1\left(1-(5)^{\gamma-1}\right)$$

Substitute numerical values and evaluate W_{on}:

$$W_{\text{on}} = -2.49\left(\frac{30.0\,\text{g}}{28.01\,\text{g/mol}}\right)\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(273\,\text{K})\left(1-(5)^{1.4-1}\right) = \boxed{5.49\,\text{kJ}}$$

87 •• How much work must be done on 30.0 g of carbon dioxide (CO_2) at standard temperature and pressure to compress it to one-fifth of its initial volume if the process is (*a*) isothermal, (*b*) adiabatic?

Picture the Problem (*a*) Let the subscripts 1 and 2 refer to the initial and final state respectively. Because the gas is initially at standard temperature and pressure, we know that V_1 = 22.4 L/mol, P_1 = 1 atm, and T_1 = 273 K. We can use $W = -nRT\ln(V_2/V_1)$ to find the work done on the gas during an isothermal compression. (*b*) We can use $W_{\text{on}} = -nC_{\text{V}}(T_1 - T_2)$ to find the work done on the gas during the adiabatic compression. Note that γ = 1.3 for triatomic gasses and see Appendix C for the molar mass of CO_2.

(*a*) Express the work done on the gas in compressing it isothermally:

$$W_{\text{on}} = -nRT\ln\left(\frac{V_2}{V_1}\right)$$

Because the number of moles of CO_2 is the mass m of CO_2 divided by its molar mass:

$$W_{\text{on}} = -\frac{m}{M}RT\ln\left(\frac{V_2}{V_1}\right)$$

Substitute numerical values and evaluate W_{on}:

$$W_{\text{on}} = -\left(\frac{30.0\,\text{g}}{44.01\,\text{g/mol}}\right)\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(273\,\text{K})\ln\left(\frac{1}{5}\right) = \boxed{2.49\,\text{kJ}}$$

(*b*) Express the work done on the gas in compressing it adiabatically:

$$W_{\text{on}} = -nC_{\text{V}}(T_1 - T_2) = -\frac{m}{M}C_{\text{V}}(T_1 - T_2)$$

Using the equation for a quasi-static adiabatic process, relate the initial and final temperatures and volumes:

$$T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1} \Rightarrow T_2 = T_1\left(\frac{V_1}{V_2}\right)^{\gamma-1}$$

Substituting for T_2 and V_2 and simplifying gives:

$$W_{\text{on}} = -\frac{m}{M}C_{\text{V}}\left(T_1 - T_1\left(\frac{V_1}{\frac{1}{5}V_1}\right)^{\gamma-1}\right)$$

$$= -\frac{m}{M}C_{\text{V}}T_1\left(1-(5)^{\gamma-1}\right)$$

Because $C_{\text{V}} = 3.39R$ for CO_2 (see Table 18-3):

$$W_{\text{on}} = -3.39\frac{m}{M}RT_1\left(1-(5)^{\gamma-1}\right)$$

Substitute numerical values and evaluate W_{on}:

$$W_{\text{on}} = -3.39\left(\frac{30.0\,\text{g}}{44.01\,\text{g/mol}}\right)\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(273\,\text{K})\left(1-(5)^{1.3-1}\right) = \boxed{3.26\,\text{kJ}}$$

88 •• How much work must be done on 30.0 g of argon (Ar) at standard temperature and pressure to compress it to one-fifth of its initial volume if the process is (*a*) isothermal, (*b*) adiabatic?

Picture the Problem (*a*) Let the subscripts 1 and 2 refer to the initial and final state respectively. Because the gas is initially at standard temperature and pressure, we know that V_1 = 22.4 L/mol, P_1 = 1 atm, and T_1 = 273 K. We can use $W = -nRT\ln(V_2/V_1)$ to find the work done on the gas during an isothermal

compression. (*b*) We can use $W_{\text{on}} = -nC_{\text{V}}(T_1 - T_2)$ to find the work done on the gas during the adiabatic compression. Note that γ = 1.67 for monatomic gasses and see Appendix C for the molar mass of Ar.

(*a*) Express the work done on the gas in compressing it isothermally:

$$W_{\text{on}} = -nRT\ln\left(\frac{V_2}{V_1}\right)$$

Because the number of moles of Ar is the mass *m* of Ar divided by its molar mass:

$$W_{\text{on}} = -\frac{m}{M}RT\ln\left(\frac{V_2}{V_1}\right)$$

Substitute numerical values and evaluate W_{on}:

$$W_{\text{on}} = -\left(\frac{30.0\,\text{g}}{39.948\,\text{g/mol}}\right)\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(273\,\text{K})\ln\left(\frac{1}{5}\right) = \boxed{2.74\,\text{kJ}}$$

(*b*) Express the work done on the gas in compressing it adiabatically:

$$W_{\text{on}} = -nC_{\text{V}}(T_1 - T_2) = -\frac{m}{M}C_{\text{V}}(T_1 - T_2)$$

Using the equation for a quasi-static adiabatic process, relate the initial and final temperatures and volumes:

$$T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1} \Rightarrow T_2 = T_1\left(\frac{V_1}{V_2}\right)^{\gamma-1}$$

Substituting for T_2 and V_2 and simplifying gives:

$$W_{\text{on}} = -\frac{m}{M}C_{\text{V}}\left(T_1 - T_1\left(\frac{V_1}{\frac{1}{5}V_1}\right)^{\gamma-1}\right)$$

$$= -\frac{m}{M}C_{\text{V}}T_1\left(1 - (5)^{\gamma-1}\right)$$

Because $C_{\text{V}} = 1.50R$ for Ar (see Table 18-3):

$$W_{\text{on}} = -1.50\frac{m}{M}RT_1\left(1 - (5)^{\gamma-1}\right)$$

Substitute numerical values and evaluate W_{on}:

$$W_{\text{on}} = -1.50\left(\frac{30.0\,\text{g}}{39.95\,\text{g/mol}}\right)\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(273\,\text{K})\left(1 - (5)^{1.67-1}\right) = \boxed{4.92\,\text{kJ}}$$

89 •• **[SSM]** A thermally insulated system consists of 1.00 mol of a diatomic gas at 100 K and 2.00 mol of a solid at 200 K that are separated by a rigid insulating wall. Find the equilibrium temperature of the system after the

insulating wall is removed, assuming that the gas obeys the ideal-gas law and that the solid obeys the Dulong–Petit law.

Picture the Problem We can use conservation of energy to relate the equilibrium temperature to the heat capacities of the gas and the solid. We can apply the Dulong-Petit law to find the heat capacity of the solid at constant volume and use the fact that the gas is diatomic to find its heat capacity at constant volume.

Apply conservation of energy to this process:

$$\Delta Q = Q_{\text{gas}} + Q_{\text{solid}} = 0$$

Use $Q = C_{\text{V}}\Delta T$ to substitute for Q_{gas} and Q_{solid}:

$$C_{\text{V,gas}}\left(T_{\text{equil}} - 100\,\text{K}\right) + C_{\text{V,solid}}\left(T_{\text{equil}} - 200\,\text{K}\right) = 0$$

Solving for T_{equil} yields:

$$T_{\text{equil}} = \frac{(100\,\text{K})\left(C_{\text{V,gas}}\right) + (200\,\text{K})\left(C_{\text{V,solid}}\right)}{C_{\text{V,gas}} + C_{\text{V,solid}}}$$

Using the Dulong-Petit law, determine the heat capacity of the solid at constant volume:

$$C_{\text{V,solid}} = 3n_{\text{solid}}R$$

The heat capacity of the gas at constant volume is given by:

$$C_{\text{V,gas}} = \tfrac{5}{2}n_{\text{gas}}R$$

Substitute for $C_{\text{V,solid}}$ and $C_{\text{V,gas}}$ and simplify to obtain:

$$T_{\text{equil}} = \frac{(100\,\text{K})\left(\frac{5}{2}n_{\text{gas}}R\right) + (200\,\text{K})\left(3n_{\text{solid}}R\right)}{\frac{5}{2}n_{\text{gas}}R + 3n_{\text{solid}}R} = \frac{(100\,\text{K})\left(\frac{5}{2}n_{\text{gas}}\right) + (200\,\text{K})\left(3n_{\text{solid}}\right)}{\frac{5}{2}n_{\text{gas}} + 3n_{\text{solid}}}$$

Substitute numerical values for n_{gas} and n_{solid} and evaluate T_{equil}:

$$T_{\text{equil}} = \frac{(100\,\text{K})\left(\frac{5}{2}\right)(1.00\,\text{mol}) + (200\,\text{K})(3)(2.00\,\text{mol})}{\frac{5}{2}(1.00\,\text{mol}) + 3(2.00\,\text{mol})} = \boxed{171\,\text{K}}$$

90 •• When an ideal gas undergoes a temperature change at constant volume, its internal energy change is given by the formula $\Delta E_{\text{int}} = C_{\text{v}}\Delta T$. However, this formula correctly gives the change in internal energy whether the volume remains constant or not. (*a*) Explain why this formula gives correct results for an ideal gas even when the volume changes. (*b*) Using this formula, along with the first law of thermodynamics, show that for an ideal gas $C_{\text{p}} = C_{\text{v}} + nR$.

Picture the Problem

(*a*) $\Delta E_{\text{int}} = C_{\text{V}}\Delta T$ correctly gives the change in internal energy when the temperature changes and the volume is not constant because ΔE_{int} is the same for *all* gas processes that have the same ΔT. For an ideal gas, the internal energy is the sum of the kinetic energies of the gas molecules and this sum is proportional to kT. Any two processes that change the thermal energy of the gas by ΔE_{int} will cause the same temperature change ΔT. Consequently, ΔE_{int} is independent of the process that takes the gas from one state to another.

(*b*) Use the first law of thermodynamics to relate the work done on the gas, the heat entering the gas, and the change in the internal energy of the gas:

$$\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$$

Substituting for ΔE_{int} yields:

$$C_{\text{V}}\Delta T = Q_{\text{in}} + W_{\text{on}}$$

The work done on the gas during a constant-pressure process is given by:

$$W_{\text{on}} = -P\Delta V = -P(V_{\text{f}} - V_{\text{i}})$$

Use the ideal gas law to substitute for V_{f} and V_{i} and then simplify to obtain:

$$W_{\text{on}} = -P\left(\frac{nRT_{\text{f}}}{P} - \frac{nRT_{\text{i}}}{P}\right) = -nR(T_{\text{f}} - T_{\text{i}})$$
$$= -nR\Delta T$$

Substituting for W_{on} gives:

$$C_{\text{V}}\Delta T = Q_{\text{in}} - nR\Delta T$$

Solve for Q_{in} and simplify to obtain:

$$Q_{\text{in}} = C_{\text{V}}\Delta T + nR\Delta T = (C_{\text{V}} + nR)\Delta T$$
$$= C_{\text{P}}\Delta T$$

where $\boxed{C_{\text{P}} = C_{\text{V}} + nR}$

91 •• An insulated cylinder is fitted with an insulated movable piston to maintain constant pressure. The cylinder initially contains 100 g of ice at –10ºC. Heat is transferred to the ice at a constant rate by a 100-W heater. Make a graph showing the temperature of the ice/water/ steam as a function of time starting at t_i when the temperature is –10ºC and ending at t_{f} when the temperature is 110ºC.

Picture the Problem Knowing the rate at which energy is supplied, we can obtain the data we need to plot this graph by finding the time required to warm the ice to 0°C, melt the ice, warm the water formed from the ice to 100°C, vaporize the water, and warm the water to 110°C.

Find the time required to warm the ice to 0°C:

$$\Delta t_1 = \frac{mc_{\text{ice}}\Delta T}{P} = \frac{(0.100\,\text{kg})\left(2.0\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(0°\text{C}-(-10°\text{C}))}{100\,\frac{\text{J}}{\text{s}}} = 20.0\,\text{s} \approx 0.3\,\text{min}$$

Find the time required to melt the ice:

$$\Delta t_2 = \frac{mL_{\text{f}}}{P} = \frac{(0.100\,\text{kg})\left(333.5\,\frac{\text{kJ}}{\text{kg}}\right)}{100\,\frac{\text{J}}{\text{s}}}$$

$$= 333.5\,\text{s} \approx 5.6\,\text{min}$$

Find the time required to heat the water to 100°C:

$$\Delta t_3 = \frac{mc_{\text{w}}\Delta T}{P}$$

$$= \frac{(0.100\,\text{kg})\left(4.18\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(100°\text{C})}{100\,\frac{\text{J}}{\text{s}}}$$

$$= 418\,\text{s} \approx 7.0\,\text{min}$$

Find the time required to vaporize the water:

$$\Delta t_4 = \frac{mL_{\text{V}}}{P} = \frac{(0.100\,\text{kg})\left(2257\,\frac{\text{kJ}}{\text{kg}}\right)}{100\,\frac{\text{J}}{\text{s}}}$$

$$= 2257\,\text{s} \approx 37.6\,\text{min}$$

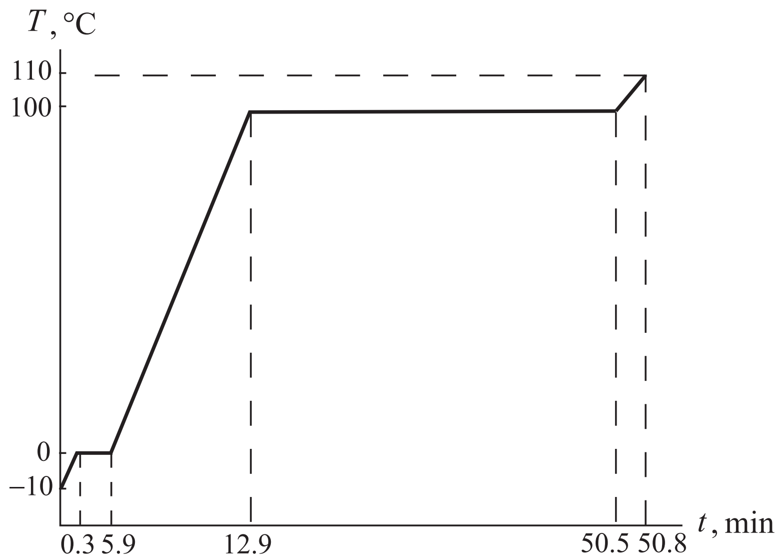
Find the time required to heat the vapor to 110°C:

$$\Delta t_5 = \frac{mc_{\text{steam}}\Delta T}{P}$$

$$= \frac{(0.100\,\text{kg})\left(2.0\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(10°\text{C})}{100\,\frac{\text{J}}{\text{s}}}$$

$$= 20.0\,\text{s} \approx 0.3\,\text{min}$$

A graph of T as a function of time follows:



92 •• (*a*) In this problem, 2.00 mol of a diatomic ideal gas expands adiabatically and quasi-statically. The initial temperature of the gas is 300 K. The work done by the gas during the expansion is 3.50 kJ. What is the final temperature of the gas? (*b*) Compare your result to the result you would get if the gas were monatomic.

Picture the Problem We know that, for an adiabatic process, $Q_{in} = 0$. Hence the work done by the expanding gas equals the change in its internal energy. Because we're given the work done by the gas during the expansion, we can express the change in the temperature of the gas in terms of this work and C_V.

(*a*) Express the final temperature of the gas as a result of its expansion:

$$T_f = T_i + \Delta T$$

Apply the equation for adiabatic work and solve for ΔT:

$$W_{adiabatic} = -C_V \Delta T$$

and

$$\Delta T = -\frac{W_{adiabatic}}{C_V} = -\frac{W_{adiabatic}}{\frac{5}{2}nR}$$

Substitute for ΔT to obtain:

$$T_f = T_i - \frac{W_{adiabatic}}{\frac{5}{2}nR}$$

Substitute numerical values and evaluate T_f for a diatomic gas:

$$T_f = 300\,\text{K} - \frac{3.50\,\text{kJ}}{\frac{5}{2}(2.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)} = \boxed{216\,\text{K}}$$

(*b*) Because a monatomic gas has only 3 degrees of freedom:

$$C_V = \tfrac{3}{2}nR$$

and

$$T_f = T_i - \frac{W_{\text{adiabatic}}}{\frac{3}{2}nR}$$

Substitute numerical values and evaluate T_f for a monatomic gas:

$$T_f = 300\,\text{K} - \frac{3.50\,\text{kJ}}{\frac{3}{2}(2.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)} = \boxed{160\,\text{K}}$$

93 •• A vertical insulated cylinder is divided into two parts by a movable piston of mass *m*. The piston is initially held at rest. The top part is evacuated and the bottom part is filled with 1.00 mol of diatomic ideal gas at temperature 300 K. After the piston is released and the system comes to equilibrium, the volume occupied by gas is halved. Find the final temperature of the gas.

Picture the Problem Let the subscripts 1 and 2 refer to the initial and final states in this adiabatic expansion. We can use an equation describing a quasi-static adiabatic process to express the final temperature as a function of the initial temperature and the initial and final volumes.

Using the equation for a quasi-static adiabatic process, relate the initial and final volumes and temperatures:

$$T_2 V_2^{\gamma-1} = T_1 V_1^{\gamma-1}$$

Solve for T_2 and simplify to obtain:

$$T_2 = T_1\left(\frac{V_1}{V_2}\right)^{\gamma-1} = T_1\left(\frac{V_1}{\frac{1}{2}V_1}\right)^{\gamma-1} = T_1(2)^{\gamma-1}$$

Substitute the numerical value for T_1 and evaluate T_2:

$$T_2 = (300\,\text{K})(2)^{1.4-1} = \boxed{396\,\text{K}}$$

94 ••• According to the Einstein model of a crystalline solid, the internal energy per mole is given by $U=\dfrac{3N_{\text{A}}kT_{\text{E}}}{e^{T_{\text{E}}/T}-1}$ where T_{E} is a characteristic temperature called the *Einstein temperature*, and T is the temperature of the solid in kelvins. Use this expression to show that a crystalline solid's molar heat capacity at constant volume is given by $c'_{\text{V}}=3R\left(\dfrac{T_E}{T}\right)^2\dfrac{e^{T_{\text{E}}/T}}{\left(e^{T_{\text{E}}/T}-1\right)^2}$.

Picture the Problem The molar heat capacity at constant volume is related to the internal energy per mole according to $c'_v=\dfrac{1}{n}\dfrac{dU}{dT}$. We can differentiate U with respect to temperature and use $nR = Nk$ or $R = N_{\text{A}}k$ to establish the result given in the problem statement.

From the Einstein model of a crystalline solid, the internal energy per mole is given by:

$$U=\frac{3N_{\text{A}}kT_{\text{E}}}{e^{T_{\text{E}}/T}-1}$$

Relate the molar heat capacity at constant volume to the internal energy per mol:

$$c'_{\text{V}}=\frac{1}{n}\frac{dU}{dT}$$

Use $c'_{\text{V}}=\dfrac{1}{n}\dfrac{dU}{dT}$ to express c'_{V}:

$$c'_{\text{V}}=\frac{1}{n}\frac{d}{dT}\left[\frac{3N_{\text{A}}kT_{\text{E}}}{e^{T_{\text{E}}/T}-1}\right]=3RT_{\text{E}}\frac{d}{dT}\left[\frac{1}{e^{T_{\text{E}}/T}-1}\right]=3RT_{\text{E}}\left[\frac{-1}{\left(e^{T_{\text{E}}/T}-1\right)^2}\right]\frac{d}{dT}\left(e^{T_{\text{E}}/T}-1\right)$$

$$=3RT_{\text{E}}\left[\frac{-1}{\left(e^{T_{\text{E}}/T}-1\right)^2}\right]\left[e^{T_{\text{E}}/T}\left(-\frac{T_E}{T^2}\right)\right]=\boxed{3R\left(\frac{T_E}{T}\right)^2\frac{e^{T_{\text{E}}/T}}{\left(e^{T_{\text{E}}/T}-1\right)^2}}$$

95 ••• [SSM] (*a*) Use the results of Problem 94 to show that in the limit that $T >> T_{\text{E}}$, the Einstein model gives the same expression for specific heat that the Dulong–Petit law does. (*b*) For diamond, T_{E} is approximately 1060 K. Integrate numerically $dE_{\text{int}}=c'_{\text{v}}\,dT$ to find the increase in the internal energy if 1.00 mol of diamond is heated from 300 to 600 K.

Picture the Problem (*a*) We can rewrite our expression for c'_{V} by dividing its numerator and denominator by $e^{T_{\mathrm{E}}/T}$ and then using the power series for e^x to show that, for $T > T_{\mathrm{E}}$, $c'_{\mathrm{V}} \approx 3R$. In Part (*b*), we can use the result of Problem 94 to obtain values for c'_{V} every 100 K between 300 K and 600 K and use this data to find ΔU numerically.

(*a*) From Problem 94 we have:

$$c'_{\mathrm{V}} = 3R\left(\frac{T_{\mathrm{E}}}{T}\right)^2 \frac{e^{T_{\mathrm{E}}/T}}{\left(e^{T_{\mathrm{E}}/T}-1\right)^2}$$

Divide the numerator and denominator by $e^{T_{\mathrm{E}}/T}$ to obtain:

$$c'_{\mathrm{V}} = 3R\left(\frac{T_{\mathrm{E}}}{T}\right)^2 \frac{1}{\dfrac{e^{2T_{\mathrm{E}}/T}-2e^{T_{\mathrm{E}}/T}+1}{e^{T_{\mathrm{E}}/T}}}$$

$$= 3R\left(\frac{T_{\mathrm{E}}}{T}\right)^2 \frac{1}{e^{T_{\mathrm{E}}/T}-2+e^{-T_{\mathrm{E}}/T}}$$

Express the exponential terms in their power series to obtain:

$$e^{T_{\mathrm{E}}/T}-2+e^{-T_{\mathrm{E}}/T} = 1+\frac{T_{\mathrm{E}}}{T}+\frac{1}{2}\left(\frac{T_{\mathrm{E}}}{T}\right)^2+\ldots-2+1-\frac{T_{\mathrm{E}}}{T}+\frac{1}{2}\left(\frac{T_{\mathrm{E}}}{T}\right)^2+\ldots$$

$$\approx \left(\frac{T_{\mathrm{E}}}{T}\right)^2 \text{ for } T >> T_{\mathrm{E}}$$

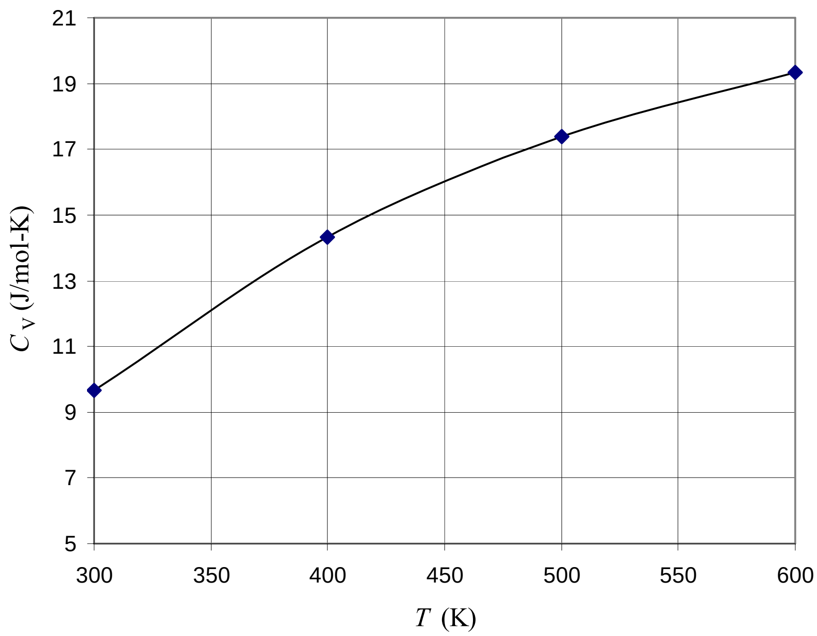
Substitute for $e^{T_{\mathrm{E}}/T}-2+e^{-T_{\mathrm{E}}/T}$ to obtain:

$$c'_{\mathrm{V}} \approx 3R\left(\frac{T_{\mathrm{E}}}{T}\right)^2 \frac{1}{\left(\dfrac{T_{\mathrm{E}}}{T}\right)^2} = \boxed{3R}$$

(*b*) Use the result of Problem 94 to verify the following table:

T	(K)	300	400	500	600
c_{V}	(J/mol·K)	9.65	14.33	17.38	19.35

The following graph of specific heat as a function of temperature was plotted using a spreadsheet program:



Integrate numerically, using the formula for the area of a trapezoid, to obtain:

$$\begin{aligned}\Delta U &= \tfrac{1}{2}(1.00\text{ mol})(100\text{ K})(9.65+14.33)\frac{\text{J}}{\text{mol}\cdot\text{K}}\\ &\quad+\tfrac{1}{2}(1.00\text{ mol})(100\text{ K})(14.33+17.38)\frac{\text{J}}{\text{mol}\cdot\text{K}}\\ &\quad+\tfrac{1}{2}(1.00\text{ mol})(100\text{ K})(17.38+19.35)\frac{\text{J}}{\text{mol}\cdot\text{K}}\\ &= \boxed{4.62\text{ kJ}}\end{aligned}$$

96 ••• Use the results of the Einstein model in Problem 94 to determine the molar internal energy of diamond (T_E = 1060 K) at 300 K and 600 K, and thereby the increase in internal energy as diamond is heated from 300 K to 600 K. Compare your result to that of Problem 95.

Picture the Problem We can simplify our calculations by relating Avogadro's number N_A, Boltzmann's constant k, the number of moles n, and the number of molecules N in the gas and solving for N_Ak. We can then calculate $U_{300\text{ K}}$, $U_{600\text{ K}}$, and their difference.

Express the increase in internal energy per mole resulting from the heating of diamond:

$$\Delta U = U_{600\,\text{K}} - U_{300\,\text{K}} \qquad (1)$$

Express the relationship between Avogadro's number N_A, Boltzmann's constant k, the number of moles n, and the number of molecules N in the gas:

$$nR = Nk \Rightarrow R = \frac{N}{n}k = N_A k$$

Substitute in the given equation to obtain:

$$U = \frac{3RT_E}{e^{T_E/T} - 1}$$

Determine $U_{300\,\text{K}}$:

$$U_{300\,\text{K}} = \frac{3\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(1060\,\text{K})}{e^{1060\,\text{K}/300\,\text{K}} - 1} = 795.4\,\text{J} = \boxed{795\,\text{J}}$$

Determine $U_{600\,\text{K}}$:

$$U_{600\,\text{K}} = \frac{3\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(1060\,\text{K})}{e^{1060\,\text{K}/600\,\text{K}} - 1} = 5.4498\,\text{kJ} = \boxed{5.45\,\text{kJ}}$$

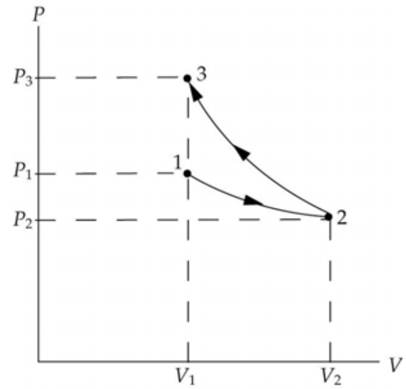
Substituting in equation (1) yields:

$$\Delta U = U_{600\,\text{K}} - U_{300\,\text{K}} = 5.4498\,\text{kJ} - 795.4\,\text{J} = \boxed{4.65\,\text{kJ}}$$

This result agrees with the result of Problem 95 to within 1%.

97 ••• During an isothermal expansion, an ideal gas at an initial pressure P_0 expands until its volume is twice its initial volume V_0. (*a*) Find its pressure after the expansion. (*b*) The gas is then compressed adiabatically and quasi-statically until its volume is V_0 and its pressure is $1.32P_0$. Is the gas monatomic, diatomic, or polyatomic? (*c*) How does the translational kinetic energy of the gas change in each stage of this process?

Picture the Problem The isothermal expansion followed by an adiabatic compression is shown on the PV diagram. The path 1→2 is isothermal and the path 2→3 is adiabatic. We can apply the ideal-gas law for a fixed amount of gas and an isothermal process to find the pressure at point 2 and the pressure-volume relationship for a quasi-static adiabatic process to determine γ.



(*a*) Relate the initial and final pressures and volumes for the isothermal expansion and solve for and evaluate the final pressure:

$$P_1V_1 = P_2V_2$$

and

$$P_2 = P_1\frac{V_1}{V_2} = P_0\frac{V_1}{2V_1} = \boxed{\tfrac{1}{2}P_0}$$

(*b*) Relate the initial and final pressures and volumes for the adiabatic compression:

$$P_2V_2^{\gamma} = P_3V_3^{\gamma}$$

or

$$\tfrac{1}{2}P_0(2V_0)^{\gamma} = 1.32P_0V_0^{\gamma}$$

which simplifies to $2^{\gamma} = 2.64$

Take the natural logarithm of both sides of this equation and solve for and evaluate γ:

$$\gamma\ln 2 = \ln 2.64 \Rightarrow \gamma = \frac{\ln 2.64}{\ln 2} = 1.40$$

and the gas is $\boxed{\text{diatomic}}$.

(*c*) During the isothermal process, *T* is constant and the translational kinetic energy is unchanged. During the adiabatic process, the translational kinetic energy increases by a factor of 1.32.

98 ••• If a hole is punctured in a tire, the gas inside will gradually leak out. Assume the following: the area of the hole is *A*; the tire volume is *V*; and the time, τ, it takes for most of the air to leak out of the tire can be expressed in terms of the ratio A/V, the temperature *T*, the Boltzmann constant *k*, and the initial mass *m* of the gas inside the tire. (*a*) Based on these assumptions, use dimensional analysis to find an estimate for τ. (*b*) Use the result of Part (*a*) to estimate the time it takes for a car tire with a nail hole punched in it to go flat.

Picture the Problem In (*a*) we'll assume that $\tau = f(A/V, T, k, m)$ with the factors dependent on constants *a, b, c,* and *d* that we'll find using dimensional analysis. In (*b*) we'll use our result from (*a*) and assume that the diameter of the puncture is about 2 mm, that the tire volume is 0.1 m^3, and that the air temperature is 20°C.

(*a*) Express $\tau = f(A/V, T, k, m)$:

$$\tau = \left(\frac{A}{V}\right)^a (T)^b (k)^c (m)^d \qquad (1)$$

Rewrite this equation in terms of the dimensions of the physical quantities to obtain:

$$\mathrm{T}^1 = (\mathrm{L})^{-a}(\mathrm{K})^b\left(\frac{\mathrm{ML}^2}{\mathrm{T}^2\mathrm{K}}\right)^c(\mathrm{M})^d$$

where K represents the dimension of temperature.

Simplify this dimensional equation to obtain:

$$\mathrm{T}^1 = \mathrm{L}^{-a}\mathrm{K}^b\mathrm{M}^c\mathrm{L}^{2c}\mathrm{K}^{-c}\mathrm{T}^{-2c}\mathrm{M}^d$$

or

$$\mathrm{T}^1 = \mathrm{L}^{2c-a}\mathrm{K}^{b-c}\mathrm{M}^{c+d}\mathrm{T}^{-2c}$$

Equate exponents to obtain:

$\mathrm{T}:\ -2c = 1$,
$\mathrm{L}:\ 2c - a = 0$,
$\mathrm{K}:\ b - c = 0$,
and
$\mathrm{M}:\ c + d = 0$

Solve these equations simultaneously to obtain:

$a = -1$, $b = -\frac{1}{2}$, $c = -\frac{1}{2}$, and $d = \frac{1}{2}$

Substituting in equation (1) yields:

$$\tau = \left(\frac{A}{V}\right)^{-1}(T)^{-\frac{1}{2}}(k)^{-\frac{1}{2}}(m)^{\frac{1}{2}} = \boxed{\frac{V}{A}\sqrt{\frac{m}{kT}}}$$

(*b*) Substitute numerical values and evaluate τ:

$$\tau = \frac{0.1\,\mathrm{m}^3}{\frac{\pi}{4}\left(2\times10^{-3}\,\mathrm{m}\right)^2}\sqrt{\frac{\left(1.293\,\mathrm{kg/m}^3\right)\left(0.1\,\mathrm{m}^3\right)}{\left(1.381\,\mathrm{J/K}\right)\left(293\,\mathrm{K}\right)}} = 569\,\mathrm{s} \approx \boxed{9\,\mathrm{min}}$$

Chapter 19
The Second Law of Thermodynamics

Conceptual Problems

1 • Modern automobile gasoline engines have efficiencies of about 25%. About what percentage of the heat of combustion is not used for work but released as heat? (*a*) 25%, (*b*) 50%, (*c*) 75%, (*d*) 100%, (*e*) You cannot tell from the data given.

Determine the Concept The efficiency of a heat engine is the ratio of the work done per cycle W to the heat absorbed from the high-temperature reservoir Q_h. The percentage of the heat of combustion (heat absorbed from the high-temperature reservoir) is the ratio of Q_c to Q_h. We can use the relationship between W, Q_h, and Q_c ($W = Q_h - Q_c$) to find Q_c/Q_h.

Use the definition of efficiency and the relationship between W, Q_h, and Q_c to obtain:

$$\varepsilon = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h}$$

Solving for Q_c/Q_h yields:

$$\frac{Q_c}{Q_h} = 1 - \varepsilon$$

Substitute for ε to obtain:

$$\frac{Q_c}{Q_h} = 1 - 0.25 = 0.75$$

and $\boxed{(c)}$ is correct.

2 • If a heat engine does 100 kJ of work per cycle while releasing 400 kJ of heat, what is its efficiency? (*a*) 20%, (*b*) 25%, (*c*) 80%, (*d*) 400%, (*e*) You cannot tell from the data given.

Determine the Concept The efficiency of a heat engine is the ratio of the work done per cycle W to the heat absorbed from the high-temperature reservoir Q_h. We can use the relationship between W, Q_h, and Q_c ($W = Q_h - Q_c$) to express the efficiency of the heat engine in terms of Q_c and W.

Use the definition of efficiency and the relationship between W, Q_h, and Q_c to obtain:

$$\varepsilon = \frac{W}{Q_h} = \frac{W}{W + Q_c} = \frac{1}{1 + \frac{Q_c}{W}}$$

Substitute for Q_c and W to obtain:

$$\varepsilon = \frac{1}{1 + \frac{400\text{ kJ}}{100\text{ kJ}}} = 0.2$$

and $\boxed{(a)}$ is correct.

3 • If the heat absorbed by a heat engine is 600 kJ per cycle, and it releases 480 kJ of heat each cycle, what is its efficiency? (*a*) 20%, (*b*) 80%, (*c*) 100%, (*d*) You cannot tell from the data given.

Determine the Concept The efficiency of a heat engine is the ratio of the work done per cycle W to the heat absorbed from the high-temperature reservoir Q_h. We can use the relationship between W, Q_h, and Q_c ($W = Q_h - Q_c$) to express the efficiency of the heat engine in terms of Q_c and Q_h.

Use the definition of efficiency and the relationship between W, Q_h, and Q_c to obtain:

$$\varepsilon = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h}$$

Substitute for Q_c and Q_h to obtain:

$$\varepsilon = 1 - \frac{480\text{ kJ}}{600\text{ kJ}} = 0.2$$

and $\boxed{(a)}$ is correct.

4 • Explain what distinguishes a refrigerator from a ″heat pump.″

Determine the Concept The job of a refrigerator is to move heat from its cold interior to the warmer kitchen environment. This process moves heat in a direction that is opposite its ″natural″ direction of flow, analogous to the use of a water pump to pump water out of a boat. The term heat pumps is used to describe devices, such as air conditioners, that are used to cool living and working spaces in the summer and warm them in the winter.

5 • **[SSM]** An air conditioner's COP is mathematically identical to that of a refrigerator, that is, $\text{COP}_{\text{AC}} = \text{COP}_{\text{ref}} = \frac{Q_c}{W}$. However a heat pump's COP is defined differently, as $\text{COP}_{\text{hp}} = \frac{Q_h}{W}$. Explain clearly *why* the two COPs are defined differently. *Hint*: *Think of the end use of the three different devices.*

Determine the Concept The COP is defined so as to be a measure of the

effectiveness of the device. For a refrigerator or air conditioner, the important quantity is the heat drawn from the already colder interior, Q_c. For a heat pump, the ideas is to focus on the heat drawn into the warm interior of the house, Q_h.

6 • Explain why you cannot cool your kitchen by leaving your refrigerator door open on a hot day. (Why does turning on a room air conditioner cool down the room, but opening a refrigerator door does not?)

Determine the Concept As described by the second law of thermodynamics, more heat must be transmitted to the outside world than is removed by a refrigerator or air conditioner. The heating coils on a refrigerator are inside the room, so the refrigerator actually heats the room in which it is located. The heating coils on an air conditioner are outside one's living space, so the waste heat is vented to the outside.

7 • Why do steam-power-plant designers try to increase the temperature of the steam as much as possible?

Determine the Concept Increasing the temperature of the steam increases its energy content. In addition, it increases the Carnot efficiency, and generally increases the efficiency of any heat engine.

8 • To increase the efficiency of a Carnot engine, you should (*a*) decrease the temperature of the hot reservoir, (*b*) increase the temperature of the cold reservoir, (*c*) increase the temperature of the hot reservoir, (*d*) change the ratio of maximum volume to minimum volume.

Determine the Concept Because the efficiency of a Carnot cycle engine is given by $\varepsilon_C = 1 - \frac{T_c}{T_h}$, you should increase the temperature of the hot reservoir. $\boxed{(c)}$ is correct.

9 •• **[SSM]** Explain why the following statement is true: To increase the efficiency of a Carnot engine, you should make the difference between the two operating temperatures as large as possible; but to increase the efficiency of a Carnot cycle *refrigerator*, you should make the difference between the two operating temperatures as small as possible.

Determine the Concept A Carnot-cycle refrigerator is more efficient when the temperatures are close together because it requires less work to extract heat from an already cold interior if the temperature of the exterior is close to the temperature of the interior of the refrigerator. A Carnot-cycle heat engine is more efficient when the temperature difference is large because then more work is done by the engine for each unit of heat absorbed from the hot reservoir.

10 •• A Carnot engine operates between a cold temperature reservoir of

27°C and a high temperature reservoir of 127°C. Its efficiency is (*a*) 21%, (*b*) 25%, (*c*) 75%, (*d*) 79%.

Determine the Concept The efficiency of a Carnot cycle engine is given by $\varepsilon_{\mathrm{C}} = 1 - T_{\mathrm{c}}/T_{\mathrm{h}}$ where T_c and T_h (in kelvins) are the temperatures of the cold and hot reservoirs, respectively.

Substituting numerical values for T_c and T_h yields:

$$\varepsilon_{\mathrm{C}} = 1 - \frac{300\,\mathrm{K}}{400\,\mathrm{K}} = 0.25$$

$\boxed{(b)}$ is correct.

11 •• The Carnot engine in Problem 10 is run in reverse as a refrigerator. Its COP is (*a*) 0.33, (*b*) 1.3, (*c*) 3.0 (*d*) 4.7.

Determine the Concept The coefficient of performance of a Carnot cycle engine run in reverse as refrigerator is given by $\mathrm{COP}_{\mathrm{ref}} = \dfrac{Q_{\mathrm{c}}}{W}$. We can use the relationship between W, Q_c, and Q_h to eliminate W from this expression and then use the relationship, applicable only to a device operating in a Carnot cycle, $\dfrac{Q_{\mathrm{c}}}{Q_{\mathrm{h}}} = \dfrac{T_{\mathrm{c}}}{T_{\mathrm{h}}}$ to express the refrigerator's COP in terms of T_c and T_h.

The coefficient of performance of a refrigerator is given by:

$$\mathrm{COP}_{\mathrm{ref}} = \frac{Q_{\mathrm{c}}}{W}$$

or, because $W = Q_{\mathrm{h}} - Q_{\mathrm{c}}$,

$$\mathrm{COP}_{\mathrm{ref}} = \frac{Q_{\mathrm{c}}}{Q_{\mathrm{h}} - Q_{\mathrm{c}}}$$

Dividing the numerator and denominator of this fraction by Q_c yields:

$$\mathrm{COP}_{\mathrm{ref}} = \frac{1}{\dfrac{Q_{\mathrm{h}}}{Q_{\mathrm{c}}} - 1}$$

For a device operating in a Carnot cycle:

$$\frac{Q_{\mathrm{c}}}{Q_{\mathrm{h}}} = \frac{T_{\mathrm{c}}}{T_{\mathrm{h}}}$$

Substitute in the expression for $\mathrm{COP}_{\mathrm{ref}}$ to obtain:

$$\mathrm{COP}_{\mathrm{ref,C}} = \frac{1}{\dfrac{T_{\mathrm{h}}}{T_{\mathrm{c}}} - 1}$$

Substitute numerical values and evaluate $COP_{ref,\,C}$:

$$COP_{ref,\,C} = \frac{1}{\dfrac{400\text{ K}}{300\text{ K}} - 1} = 3.0$$

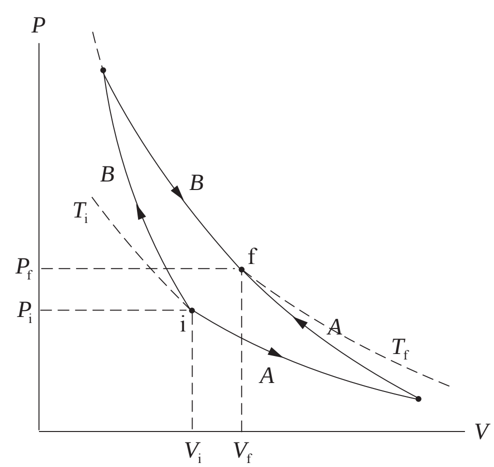
$\boxed{(c)}$ is correct.

12 •• On a humid day, water vapor condenses on a cold surface. During condensation, the entropy of the water (*a*) increases, (*b*) remains constant, (*c*) decreases, (*d*) may decrease or remain unchanged. Explain your answer.

Determine the Concept When water vapor condenses, its entropy decreases (the liquid state is a more ordered state than is the vapor state). $\boxed{(c)}$ is correct.

13 •• An ideal gas is taken reversibly from an initial state P_i, V_i, T_i to the final state P_f, V_f, T_f. Two possible paths are (A) an isothermal expansion followed by an adiabatic compression and (B) an adiabatic compression followed by an isothermal expansion. For these two paths, (*a*) $\Delta E_{int\,A} > \Delta E_{int\,B}$, (*b*) $\Delta S_A > \Delta S_B$, (*c*) $\Delta S_A < \Delta S_B$, (*d*) None of the above.

Determine the Concept The two paths are shown on the *PV* diagram to the right. We can use the concept of a state function to choose from among the alternatives given as possible answers to the problem.



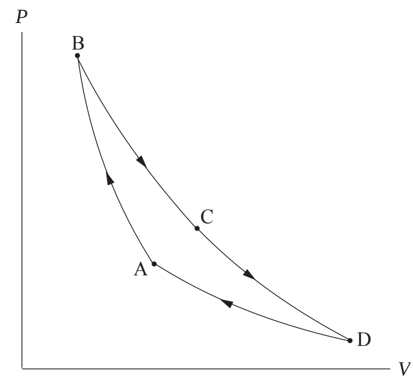
(*a*) Because E_{int} is a state function and the initial and final states are the same for the two paths, $\Delta E_{int,\,A} = \Delta E_{int,\,B}$.

(*b*) and (*c*) *S*, like E_{int}, is a state function and its change when the system moves from one state to another depends only on the system's initial and final states. It is not dependent on the process by which the change occurs. Thus $\Delta S_A = \Delta S_B$.

(*d*) $\boxed{(d)}$ is correct.

14 •• Figure 19-12 shows a thermodynamic cycle for an ideal gas on an *ST* diagram. Identify this cycle and sketch it on a *PV* diagram.

Determine the Concept The processes A→B and C→D are adiabatic and the processes B→C and D→A are isothermal. Therefore, the cycle is the Carnot cycle shown in the adjacent *PV* diagram.



15 •• Figure 19-13 shows a thermodynamic cycle for an ideal gas on an *SV* diagram. Identify the type of engine represented by this diagram.

Determine the Concept Note that A→B is an adiabatic expansion, B→C is a constant-volume process in which the entropy decreases, C→D is an adiabatic compression and D→A is a constant-volume process that returns the gas to its original state. The cycle is that of the Otto engine (see Figure 19-3). The points A, B, C, and D in Figure 19-13 correspond to points *c, d, a,* and *b,* respectively, in Figure 19-3.

16 •• Sketch an *ST* diagram of the Otto cycle. (The Otto cycle is discussed in Section 19-1.)

Determine the Concept The Otto cycle consists of four quasi-static steps. Refer to Figure 19-3. There $a \to b$ is an adiabatic compression, $b \to c$ is a constant volume heating, $c \to d$ is an adiabatic expansion and $d \to a$ is a constant-volume cooling. So, from a to b, S is constant and T increases, from b to c, heat is added to the system and both S and T increase, from $c \to d$ S is constant while T decreases, and from d to a both S and T decrease.

To determine how S depends on T along $b \to c$ and $d \to a$, consider the entropy change of the gas from point b to an arbitrary point on the path $b \to c$ where the entropy and temperature of the gas are S and T, respectively:

$$\Delta S = \frac{Q}{T}$$

where, because heat is entering the system, Q is positive.

Because $W_{\text{on}} = 0$ for this constant-volume process:

$$\Delta E_{\text{int}} = Q_{\text{in}} = Q = C_{\text{V}} \Delta T = C_{\text{V}}(T - T_b)$$

Substituting for Q yields:

$$\Delta S = \frac{C_{\text{V}}(T - T_b)}{T} = C_{\text{V}}\left(1 - \frac{T_b}{T}\right)$$

On path $b \rightarrow c$ the entropy is given by:

$$S = S_b + \Delta S = S_b + C_V\left(1 - \frac{T_b}{T}\right)$$

The first and second derivatives, dS/dT and d^2S/dT^2, give the slope and concavity of the path. Calculate these derivatives assuming C_V is constant. (For an ideal gas C_V is a positive constant.):

$$\frac{dS}{dT} = C_V \frac{T_b}{T^2}$$

$$\frac{d^2S}{dT^2} = -2C_V \frac{T_b}{T^3}$$

These results tell us that, along path $b \rightarrow c$, the slope of the path is positive and the slope decreases as T increases. The concavity of the path is negative for all T.

Following the same procedure on path $d \rightarrow a$ gives:

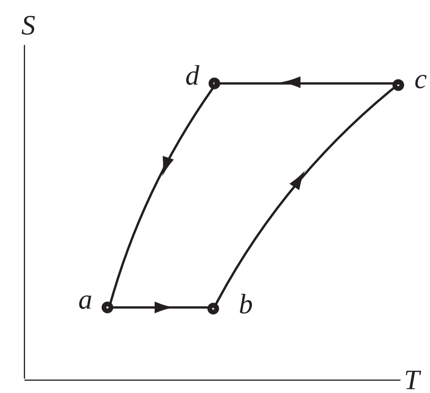
$$S = S_d + C_V\left(1 - \frac{T_d}{T}\right)$$

$$\frac{dS}{dT} = C_V \frac{T_d}{T^2}$$

$$\frac{d^2S}{dT^2} = -2C_V \frac{T_d}{T^3}$$

These results tell us that, along path $d \rightarrow a$, the slope of the path is positive and the slope decreases as T increases. The concavity of the path is negative for all T.

An ST diagram for the Otto cycle is shown to the right.



17 •• **[SSM]** Sketch an SV diagram of the Carnot cycle for an ideal gas.

Determine the Concept Referring to Figure 19-8, process $1 \rightarrow 2$ is an isothermal expansion. In this process heat is added to the system and the entropy and volume increase. Process $2 \rightarrow 3$ is adiabatic, so S is constant as V increases. Process $3 \rightarrow 4$ is an isothermal compression in which S decreases and V also decreases. Finally, process $4 \rightarrow 1$ is adiabatic, that is, isentropic, and S is constant while V decreases.

During the isothermal expansion (from point 1 to point 2) the work done by the gas equals the heat added to the gas. The change in entropy of the gas from point 1 (where the temperature is T_1) to an arbitrary point on the curve is given by:

$$\Delta S = \frac{Q}{T_1}$$

For an isothermal expansion, the work done by the gas, and thus the heat added to the gas, are given by:

$$Q = W = nRT_1 \ln\left(\frac{V}{V_1}\right)$$

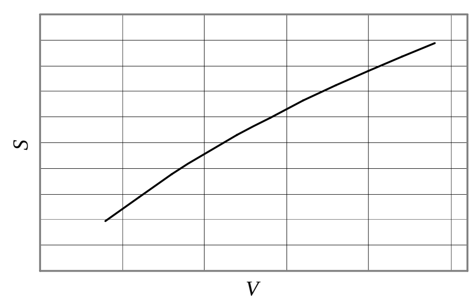
Substituting for Q yields:

$$\Delta S = nR \ln\left(\frac{V}{V_1}\right)$$

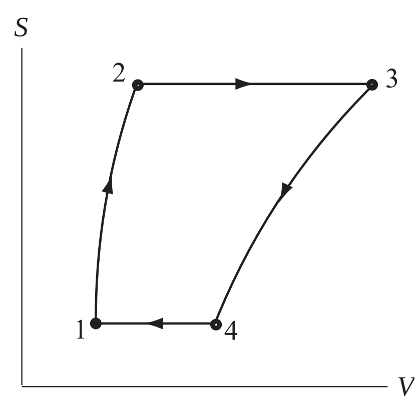
Since $S = S_1 + \Delta S$, we have:

$$S = S_1 + nR \ln\left(\frac{V}{V_1}\right)$$

The graph of S as a function of V for an isothermal expansion shown to the right was plotted using a spreadsheet program. This graph establishes the curvature of the 1→2 and 3→4 paths for the SV graph.

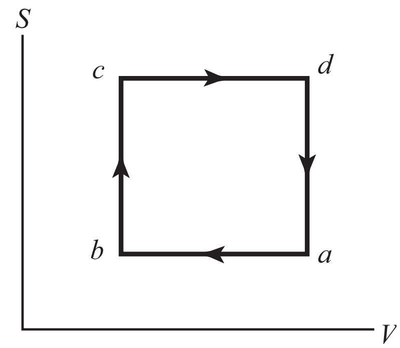


An SV graph for the Carnot cycle (see Figure 19-8) is shown to the right.



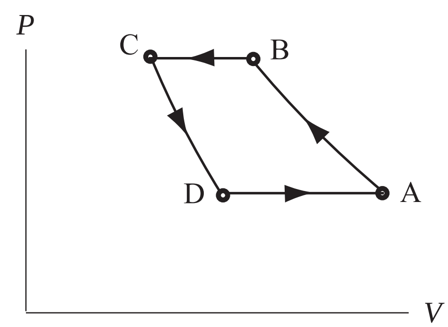
18 •• Sketch an SV diagram of the Otto cycle. (The Otto cycle is discussed in Section 19-1.)

Determine the Concept The Otto cycle is shown in Figure 19-3. Process $a\to b$ takes place adiabatically and so both $Q = 0$ and $\Delta S = 0$ along this path. Process $b\to c$ takes place at constant volume. Q_{in}, however, is positive and so, while $\Delta V = 0$ along this path, $Q > 0$ and, therefore $\Delta S > 0$. Process $c\to d$ also takes place adiabatically and so, again, both $Q = 0$ and $\Delta S = 0$ along this path. Finally, process $d\to a$ is a constant-volume process, this time with heat leaving the system and $\Delta S < 0$. A sketch of the *SV* diagram for the Otto cycle follows:



19 •• Figure 19-14 shows a thermodynamic cycle for an ideal gas on an *SP* diagram. Make a sketch of this cycle on a *PV* diagram.

Determine the Concept Process A→B is at constant entropy; that is, it is an adiabatic process in which the pressure increases. Process B→C is one in which *P* is constant and *S* decreases; heat is exhausted from the system and the volume decreases. Process C→D is an adiabatic compression. Process D→A returns the system to its original state at constant pressure. The cycle is shown in the adjacent *PV* diagram.



20 •• One afternoon, the mother of one of your friends walks into his room and finds a mess. She asks your friend how the room came to be in such a state, and your friend replies, ″Well, it is the natural destiny of any closed system to degenerate toward greater and greater levels of entropy. That’s all, Mom.″ Her reply is a sharp ″Nevertheless, you’d better clean your room!″ Your friend retorts, ″But that can’t happen. It would violate the second law of thermodynamics.″ Critique your friend’s response. Is his mother correct to ground him for not cleaning his room, or is cleaning the room really impossible?

Determine the Concept The son is out of line, here, but besides that, he’s also wrong. While it is true that systems tend to degenerate to greater levels of disorder, it is not true that order cannot be brought forth from disorder. What is

required is an agent doing work – for example, your friend – on the system in order to reduce the level of chaos and bring about order. His cleanup efforts will be rewarded with an orderly system after a sufficient time for him to complete the task. It is true that order will not come about from the disordered chaos of his room – unless he applies some elbow grease.

Estimation and Approximation

21 • Estimate the change in COP of your electric food freezer when it is removed from your kitchen to its new location in your basement, which is 8°C cooler than your kitchen.

Picture the Problem We can use the definition of the coefficient of performance to express the ratio of the coefficient of performance in your basement to the coefficient of performance in the kitchen. If we further assume that the freezer operates in a Carnot cycle, then we can use the proportion $Q_h/Q_c = T_h/T_c$ to express the ratio of the coefficients of performance in terms of the temperatures in the kitchen, basement, and freezer.

The ratio of the coefficients of performance in the basement and kitchen is given by:

$$\frac{\mathrm{COP_{basement}}}{\mathrm{COP_{kit}}} = \frac{\dfrac{Q_{c,basement}}{W_{c,basement}}}{\dfrac{Q_{c,kit}}{W_{c,kit}}}$$

Because $W = Q_h - Q_c$ for a heat engine or refrigerator:

$$\frac{\mathrm{COP_{basement}}}{\mathrm{COP_{kit}}} = \frac{\dfrac{Q_{c,basement}}{Q_{h,basement} - Q_{c,basement}}}{\dfrac{Q_{c,kit}}{Q_{h,kit} - Q_{c,kit}}}$$

Divide the numerators and denominators by $Q_{c,basement}$ and $Q_{c,kit}$ and simplify to obtain:

$$\frac{\mathrm{COP_{basement}}}{\mathrm{COP_{kit}}} = \frac{\dfrac{1}{\dfrac{Q_{h,basement}}{Q_{c,basement}} - 1}}{\dfrac{1}{\dfrac{Q_{h,kit}}{Q_{c,kit}} - 1}} = \frac{\dfrac{Q_{h,kit}}{Q_{c,kit}} - 1}{\dfrac{Q_{h,basement}}{Q_{c,basement}} - 1}$$

If we assume that the freezer unit operates in a Carnot cycle, then $\frac{Q_h}{Q_c}=\frac{T_h}{T_c}$ and our expression for the ratio of the COPs becomes:

$$\frac{\text{COP}_{\text{basement}}}{\text{COP}_{\text{kit}}}=\frac{\dfrac{T_{\text{h,kit}}}{T_{\text{c,kit}}}-1}{\dfrac{T_{\text{h,basement}}}{T_{\text{c,basement}}}-1}$$

Assuming that the temperature in your kitchen is 20°C and that the temperature of the interior of your freezer is −5°C, substitute numerical values and evaluate the ratio of the coefficients of performance:

$$\frac{\text{COP}_{\text{basement}}}{\text{COP}_{\text{kit}}}=\frac{\dfrac{293\ \text{K}}{268\ \text{K}}-1}{\dfrac{285\ \text{K}}{268\ \text{K}}-1}=1.47$$

or an increase of $\boxed{47\%}$ in the performance of the freezer!

22 •• Estimate the probability that all the molecules in your bedroom are located in the (open) closet which accounts for about 10% of the total volume of the room.

Picture the Problem The probability that all the molecules in your bedroom are located in the (open) closet is given by $p=\left(\frac{V_2}{V_1}\right)^N$ where N is the number of air molecules in your bedroom and V_1 and V_2 are the volumes of your bedroom and closet, respectively. We can use the ideal-gas law to find the number of molecules N. We'll assume that the volume of your room is about 50 m^3 and that the temperature of the air is 20°C.

If the original volume of the air in your bedroom is V_1, the probability p of finding the N molecules, normally in your bedroom, confined to your closet whose volume is V_2 is given by:

$$p=\left(\frac{V_2}{V_1}\right)^N$$

or, because $V_2=\frac{1}{10}V_1$,

$$p=\left(\frac{1}{10}\right)^N \qquad (1)$$

Use the ideal-gas law to express N:

$$N=\frac{PV}{kT}$$

Substitute numerical values and evaluate N:

$$N=\frac{(101.325\ \text{kPa})(50\ \text{m}^3)}{(1.381\times10^{-23}\ \text{J/K})(293\ \text{K})}=1.252\times10^{27}\ \text{molecules}$$

Substitute for N in equation (1) and evaluate p:

$$p = \left(\frac{1}{10}\right)^{1.252\times10^{27}} = \frac{1}{10^{1.252\times10^{27}}} = 10^{-1.252\times10^{27}} \approx \boxed{10^{-10^{27}}}$$

23 •• **[SSM]** Estimate the maximum efficiency of an automobile engine that has a compression ratio of 8.0:1.0. Assume the engine operates according to the Otto cycle and assume $\gamma = 1.4$. (The Otto cycle is discussed in Section 19-1.)

Picture the Problem The maximum efficiency of an automobile engine is given by the efficiency of a Carnot engine operating between the same two temperatures. We can use the expression for the Carnot efficiency and the equation relating V and T for a quasi-static adiabatic expansion to express the Carnot efficiency of the engine in terms of its compression ratio.

Express the Carnot efficiency of an engine operating between the temperatures T_c and T_h:

$$\varepsilon_C = 1 - \frac{T_c}{T_h}$$

Relate the temperatures T_c and T_h to the volumes V_c and V_h for a quasi-static adiabatic compression from V_c to V_h:

$$T_c V_c^{\gamma-1} = T_h V_h^{\gamma-1} \Rightarrow \frac{T_c}{T_h} = \frac{V_h^{\gamma-1}}{V_c^{\gamma-1}} = \left(\frac{V_h}{V_c}\right)^{\gamma-1}$$

Substitute for $\frac{T_c}{T_h}$ to obtain:

$$\varepsilon_C = 1 - \left(\frac{V_h}{V_c}\right)^{\gamma-1}$$

Express the compression ratio r:

$$r = \frac{V_c}{V_h}$$

Substituting for r yields:

$$\varepsilon_C = 1 - \frac{1}{r^{\gamma-1}}$$

Substitute numerical values for r and γ (1.4 for diatomic gases) and evaluate ε_C:

$$\varepsilon_C = 1 - \frac{1}{(8.0)^{1.4-1}} \approx \boxed{56\%}$$

24 •• You are working as an appliance salesperson during the summer. One day, your physics professor comes into your store to buy a new refrigerator. Wanting to buy the most efficient refrigerator possible, she asks you about the efficiencies of the available models. She decides to return the next day to buy the most efficient refrigerator. To make the sale, you need to provide her with the following estimates: (*a*) the highest COP possible for a household refrigerator, and (*b*) and the highest rate possible for the heat to be released by the refrigerator if the refrigerator uses 600 W of electrical power.

Picture the Problem If we assume that the temperature on the inside of the refrigerator is 0°C (273 K) and the room temperature to be 20°C (293 K), then the refrigerator must be able to maintain a temperature difference of 20 K. We can use the definition of the COP of a refrigerator and the relationship between the temperatures of the hot and cold reservoir and Q_h and Q_c to find an upper limit on the COP of a household refrigerator. In (*b*) we can solve the definition of COP for Q_c and differentiate the resulting equation with respect to time to estimate the rate at which heat is being drawn from the refrigerator compartment.

(*a*) Using its definition, express the COP of a household refrigerator:

$$\text{COP} = \frac{Q_c}{W} \tag{1}$$

Apply conservation of energy to the refrigerator to obtain:

$$W + Q_c = Q_h \Rightarrow W = Q_h - Q_c$$

Substitute for W and simplify to obtain:

$$\text{COP} = \frac{Q_c}{Q_h - Q_c} = \frac{1}{\dfrac{Q_h}{Q_c} - 1}$$

Assume, for the sake of finding the upper limit on the COP, that the refrigerator is a Carnot refrigerator and relate the temperatures of the hot and cold reservoirs to Q_h and Q_c:

$$\frac{Q_h}{Q_c} = \frac{T_h}{T_c}$$

Substitute for $\dfrac{Q_h}{Q_c}$ to obtain:

$$\text{COP}_{max} = \frac{1}{\dfrac{T_h}{T_c} - 1}$$

Substitute numerical values and evaluate COP_{max}:

$$\text{COP}_{max} = \frac{1}{\dfrac{293\,\text{K}}{273\,\text{K}} - 1} = 13.65 \approx \boxed{14}$$

(*b*) Solve equation (1) for Q_c:

$$Q_c = W(\text{COP}) \tag{2}$$

Differentiate equation (2) with respect to time to obtain:

$$\frac{dQ_c}{dt} = (\text{COP})\frac{dW}{dt}$$

Substitute numerical values and evaluate $\dfrac{dQ_c}{dt}$:

$$\frac{dQ_c}{dt} = (13.65)(600\,\text{J/s}) = \boxed{8.2\,\text{kW}}$$

25 •• [SSM] The average temperature of the surface of the Sun is about 5400 K, the average temperature of the surface of Earth is about 290 K. The solar constant (the intensity of sunlight reaching Earth's atmosphere) is about 1.37 kW/m^2. (*a*) Estimate the total power of the sunlight hitting Earth. (*b*) Estimate the net rate at which Earth's entropy is increasing due to this solar radiation.

Picture the Problem We can use the definition of intensity to find the total power of sunlight hitting Earth and the definition of the change in entropy to find the changes in the entropy of Earth and the Sun resulting from the radiation from the Sun.

(*a*) Using its definition, express the intensity of the Sun's radiation on Earth in terms of the power P delivered to Earth and Earth's cross sectional area A:

$$I = \frac{P}{A}$$

Solve for P and substitute for A to obtain:

$$P = IA = I\pi R^2$$

where R is the radius of Earth.

Substitute numerical values and evaluate P:

$$P = \pi\left(1.37\,\text{kW/m}^2\right)\left(6.37\times10^6\,\text{m}\right)^2 = 1.746\times10^{17}\,\text{W} = \boxed{1.75\times10^{17}\,\text{W}}$$

(*b*) Express the rate at which Earth's entropy S_{Earth} changes due to the flow of solar radiation:

$$\frac{dS_{\text{Earth}}}{dt} = \frac{P}{T_{\text{Earth}}}$$

Substitute numerical values and evaluate $\frac{dS_{\text{Earth}}}{dt}$:

$$\frac{dS_{\text{Earth}}}{dt} = \frac{1.746\times10^{17}\,\text{W}}{290\,\text{K}} = \boxed{6.02\times10^{14}\,\text{J/K}\cdot\text{s}}$$

26 •• A 1.0-L box contains N molecules of an ideal gas, and the positions of the molecules are observed 100 times per second. Calculate the average time it should take before we observe all N molecules in the left half of the box if N is equal to (*a*) 10, (*b*) 100, (*c*) 1000, and (*d*) 1.0 mole. (*e*) The best vacuums that have been created to date have pressures of about 10^{-12} torr. If a vacuum chamber has the same volume as the box, how long will a physicist have to wait before all of the gas molecules in the vacuum chamber occupy only the left half of it? Compare that to the expected lifetime of the universe, which is about 10^{10} years.

Picture the Problem If you had one molecule in a box, it would have a 50% chance of being on one side or the other. We don't care which side the molecules are on as long as they all are on one side, so with one molecule you have a 100%

chance of it being on one side or the other. With two molecules, there are four possible combinations (both on one side, both on the other, one on one side and one on the other, and the reverse), so there is a 25% (1 in 4) chance of them both being on a particular side, or a 50% chance of them both being on either side. Extending this logic, the probability of N molecules all being on one side of the box is $P = 2/2^N$, which means that, if the molecules shuffle 100 times a second, the time it would take them to cover all the combinations and all get on one side or the other is $t = \frac{2^N}{2(100)}$. In (e) we can apply the ideal gas law to find the number of molecules in 1.0 L of air at a pressure of 10^{-12} torr and an assumed temperature of 300 K.

(a) Evaluate t for $N = 10$ molecules:

$$t = \frac{2^{10}}{2(100\ \text{s}^{-1})} = 5.12\ \text{s} \approx \boxed{5\ \text{s}}$$

(b) Evaluate t for $N = 100$ molecules:

$$t = \frac{2^{100}}{2(100\ \text{s}^{-1})} = 6.34\times10^{27}\ \text{s}\times\frac{1\ \text{y}}{3.156\times10^{7}\ \text{s}} \approx \boxed{2\times10^{20}\ \text{y}}$$

(c) Evaluate t for $N = 1000$ molecules:

$$t = \frac{2^{1000}}{2(100\ \text{s}^{-1})}$$

To evaluate 2^{1000} let $10^x = 2^{1000}$ and take the logarithm of both sides of the equation to obtain:

$$(1000)\ln 2 = x\ln 10 \Rightarrow x = 301$$

Substitute to obtain:

$$t = \frac{10^{301}}{2(100\ \text{s}^{-1})} = 0.5\times10^{299}\ \text{s}\times\frac{1\ \text{y}}{3.156\times10^{7}\ \text{s}} \approx \boxed{2\times10^{291}\ \text{y}}$$

(d) Evaluate t for $N = 1.0\ \text{mol} = 6.022\times10^{23}$ molecules:

$$t = \frac{2^{6.022\times10^{23}}}{2(100\ \text{s}^{-1})}$$

To evaluate $2^{6.022\times10^{23}}$ let $10^x = 2^{6.022\times10^{23}}$ and take the logarithm of both sides of the equation to obtain:

$$(6.022\times10^{23})\ln 2 = x\ln 10 \Rightarrow x \approx 10^{23}$$

Substituting for x yields:

$$t \approx \frac{10^{10^{23}}}{2(100\ \text{s}^{-1})}\left(\frac{1\ \text{y}}{3.156\times10^{7}\ \text{s}}\right) \approx \boxed{10^{10^{23}}\ \text{y}}$$

(e) Solve the ideal gas law for the number of molecules N in the gas:

$$N = \frac{PV}{kT}$$

Assuming the gas to be at room temperature (300 K), substitute numerical values and evaluate N:

$$N = \frac{(10^{-12}\ \text{torr})(133.32\ \text{Pa/torr})(1.0\ \text{L})}{(1.381\times10^{-23}\ \text{J/K})(300\ \text{K})} = 3.22\times10^{7}\ \text{molecules}$$

Evaluate t for $N = 3.22\times10^{7}$ molecules:

$$t = \frac{2^{3.22\times10^{7}}}{2(100\ \text{s}^{-1})}$$

To evaluate $2^{3.22\times10^{7}}$ let $10^{x} = 2^{3.22\times10^{7}}$ and take the logarithm of both sides of the equation to obtain:

$$(3.22\times10^{7})\ln 2 = x\ln 10 \Rightarrow x \approx 10^{7}$$

Substituting for x yields:

$$t = \frac{10^{10^{7}}}{2(100\ \text{s}^{-1})}\times\frac{1\ \text{y}}{3.156\times10^{7}\ \text{s}} \approx \boxed{10^{10^{7}}\ \text{y}}$$

Express the ratio of this waiting time to the lifetime of the universe t_{universe}:

$$\frac{t}{t_{\text{universe}}} = \frac{10^{10^{7}}\ \text{y}}{10^{10}\ \text{y}} \approx 10^{10^{7}}$$

or

$$t \approx \boxed{10^{10^{7}}\, t_{\text{universe}}}$$

Heat Engines and Refrigerators

27 • **[SSM]** A heat engine with 20.0% efficiency does 0.100 kJ of work during each cycle. (a) How much heat is absorbed from the hot reservoir during each cycle? (b) How much heat is released to the cold reservoir during each cycle?

Picture the Problem (*a*) The efficiency of the engine is defined to be $\varepsilon = W/Q_h$ where W is the work done per cycle and Q_h is the heat absorbed from the hot reservoir during each cycle. (*b*) Because, from conservation of energy, $Q_h = W + Q_c$, we can express the efficiency of the engine in terms of the heat Q_c released to the cold reservoir during each cycle.

(*a*) Q_h absorbed from the hot reservoir during each cycle is given by:

$$Q_h = \frac{W}{\varepsilon} = \frac{100\ \text{J}}{0.200} = \boxed{500\ \text{J}}$$

(*b*) Use $Q_h = W + Q_c$ to obtain:

$$Q_c = Q_h - W = 500\ \text{J} - 100\ \text{J} = \boxed{400\ \text{J}}$$

28 • A heat engine absorbs 0.400 kJ of heat from the hot reservoir and does 0.120 kJ of work during each cycle. (*a*) What is its efficiency? (*b*) How much heat is released to the cold reservoir during each cycle?

Picture the Problem (*a*) The efficiency of the engine is defined to be $\varepsilon = W/Q_h$ where W is the work done per cycle and Q_h is the heat absorbed from the hot reservoir during each cycle. (*b*) We can apply conservation of energy to the engine to obtain $Q_h = W + Q_c$ and solve this equation for the heat Q_c released to the cold reservoir during each cycle.

(*a*) The efficiency of the heat engine is given by:

$$\varepsilon = \frac{W}{Q_h} = \frac{120\ \text{J}}{400\ \text{J}} = \boxed{30\%}$$

(*b*) Apply conservation of energy to the engine to obtain:

$$Q_h = W + Q_c \Rightarrow Q_c = Q_h - W$$

Substitute numerical values and evaluate Q_c:

$$Q_c = 400\ \text{J} - 120\ \text{J} = \boxed{280\ \text{J}}$$

29 • A heat engine absorbs 100 J of heat from the hot reservoir and releases 60 J of heat to the cold reservoir during each cycle. (*a*) What is its efficiency? (*b*) If each cycle takes 0.50 s, find the power output of this engine.

Picture the Problem We can use its definition to find the efficiency of the engine and the definition of power to find its power output.

(*a*) The efficiency of the heat engine is given by:

$$\varepsilon = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h}$$

Substitute numerical values and evaluate ε:

$$\varepsilon = 1 - \frac{60\,\text{J}}{100\,\text{J}} = \boxed{40\%}$$

(*b*) The power output *P* of this engine is the rate at which it does work:

$$P = \frac{dW}{dt} = \frac{d}{dt}\varepsilon Q_{\text{h}} = \varepsilon \frac{dQ_{\text{h}}}{dt}$$

Substitute numerical values and evaluate *P*:

$$P = (0.40)\left(\frac{100\,\text{J}}{0.500\,\text{s}}\right) = \boxed{80\,\text{W}}$$

30 • A refrigerator absorbs 5.0 kJ of heat from a cold reservoir and releases 8.0 kJ to a hot reservoir. (*a*) Find the coefficient of performance of the refrigerator. (*b*) The refrigerator is reversible. If it is run backward as a heat engine between the same two reservoirs, what is its efficiency?

Picture the Problem We can apply their definitions to find the COP of the refrigerator and the efficiency of the heat engine.

(*a*) The COP of a refrigerator is defined to be:

$$\text{COP} = \frac{Q_{\text{c}}}{W}$$

Apply conservation of energy to relate the work done per cycle to Q_{h} and Q_{c}:

$$W = Q_{\text{h}} - Q_{\text{c}}$$

Substitute for *W* to obtain:

$$\text{COP} = \frac{Q_{\text{c}}}{Q_{\text{h}} - Q_{\text{c}}}$$

Substitute numerical values and evaluate COP:

$$\text{COP} = \frac{5.0\,\text{kJ}}{8.0\,\text{kJ} - 5.0\,\text{kJ}} = \boxed{1.7}$$

(*b*) The efficiency of a heat pump is defined to be:

$$\varepsilon = \frac{W}{Q_{\text{h}}}$$

Apply conservation of energy to the heat pump to obtain:

$$\varepsilon = \frac{Q_{\text{h}} - Q_{\text{c}}}{Q_{\text{h}}} = 1 - \frac{Q_{\text{c}}}{Q_{\text{h}}}$$

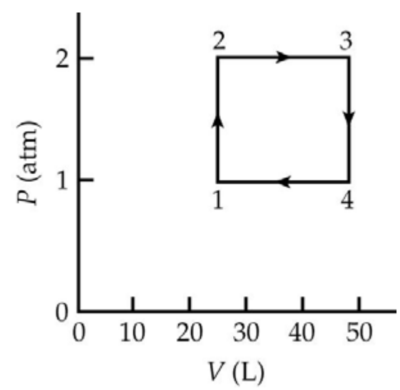
Substitute numerical values and evaluate ε:

$$\varepsilon = 1 - \frac{5.0\,\text{kJ}}{8.0\,\text{kJ}} = \boxed{38\%}$$

31 •• **[SSM]** The working substance of an engine is 1.00 mol of a monatomic ideal gas. The cycle begins at P_1 = 1.00 atm and V_1 = 24.6 L. The gas is heated at constant volume to P_2 = 2.00 atm. It then expands at constant pressure until its volume is 49.2 L. The gas is then cooled at constant volume until its pressure is again 1.00 atm. It is then compressed at constant pressure to its original state. All the steps are quasi-static and reversible. (*a*) Show this cycle on a *PV* diagram. For each step of the cycle, find the work done by the gas, the heat absorbed by the gas, and the change in the internal energy of the gas. (*b*) Find the efficiency of the cycle.

Picture the Problem To find the heat added during each step we need to find the temperatures in states 1, 2, 3, and 4. We can then find the work done on the gas during each process from the area under each straight-line segment and the heat that enters the system from $Q = C_V\Delta T$ and $Q = C_P\Delta T$. We can use the 1st law of thermodynamics to find the change in internal energy for each step of the cycle. Finally, we can find the efficiency of the cycle from the work done each cycle and the heat that *enters* the system each cycle.

(*a*) The cycle is shown to the right:



Apply the ideal-gas law to state 1 to find T_1:

$$T_1 = \frac{P_1V_1}{nR} = \frac{(1.00\,\text{atm})(24.6\,\text{L})}{(1.00\,\text{mol})\left(8.206\times10^{-2}\,\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)} = 300\,\text{K}$$

The pressure doubles while the volume remains constant between states 1 and 2. Hence:

$$T_2 = 2T_1 = 600\,K$$

The volume doubles while the pressure remains constant between states 2 and 3. Hence:

$$T_3 = 2T_2 = 1200\,K$$

The pressure is halved while the volume remains constant between states 3 and 4. Hence:

$$T_4 = \tfrac{1}{2}T_3 = 600\,K$$

For path 1→2:

$$W_{12} = P\Delta V_{12} = \boxed{0}$$

and

$$Q_{12} = C_V\Delta T_{12} = \tfrac{3}{2}R\Delta T_{12} = \tfrac{3}{2}\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K} - 300\,\text{K}) = \boxed{3.74\,\text{kJ}}$$

The change in the internal energy of the system as it goes from state 1 to state 2 is given by the 1st law of thermodynamics:

$$\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$$

Because $W_{12} = 0$:

$$\Delta E_{\text{int},12} = Q_{12} = \boxed{3.74\text{ kJ}}$$

For path 2→3:

$$W_{\text{on}} = -W_{23} = -P\Delta V_{23} = -(2.00\,\text{atm})(49.2\,\text{L} - 24.6\,\text{L})\left(\frac{101.325\,\text{J}}{\text{L}\cdot\text{atm}}\right) = \boxed{-4.99\,\text{kJ}}$$

$$Q_{23} = C_P\Delta T_{23} = \tfrac{5}{2}R\Delta T_{23} = \tfrac{5}{2}\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(1200\,\text{K} - 600\,\text{K}) = \boxed{12.5\,\text{kJ}}$$

Apply $\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$ to obtain:

$$\Delta E_{\text{int, 23}} = 12.5\text{ kJ} - 4.99\text{ kJ} = \boxed{7.5\text{ kJ}}$$

For path 3→4:

$$W_{34} = P\Delta V_{34} = \boxed{0}$$

and

$$Q_{34} = \Delta E_{\text{int},34} = C_V\Delta T_{34} = \tfrac{3}{2}R\Delta T_{34} = \tfrac{3}{2}\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K} - 1200\,\text{K}) = \boxed{-7.48\,\text{kJ}}$$

Apply $\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$ to obtain:

$$\Delta E_{\text{int, 34}} = -7.48\text{ kJ} + 0 = \boxed{-7.48\text{ kJ}}$$

For path 4→1:

$$W_{\text{on}} = -W_{41} = -P\Delta V_{41} = -(1.00\,\text{atm})(24.6\,\text{L} - 49.2\,\text{L})\left(\frac{101.325\,\text{J}}{\text{L}\cdot\text{atm}}\right) = \boxed{2.49\,\text{kJ}}$$

and

$$Q_{41} = C_{\text{P}}\Delta T_{41} = \tfrac{5}{2}R\Delta T_{41} = \tfrac{5}{2}\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(300\,\text{K} - 600\,\text{K}) = \boxed{-6.24\,\text{kJ}}$$

Apply $\Delta E_{\text{int}} = Q_{\text{in}} + W_{\text{on}}$ to obtain:

$$\Delta E_{\text{int, 41}} = -6.24\text{ kJ} + 2.49\text{ kJ} = \boxed{-3.75\text{ kJ}}$$

For easy reference, the results of the preceding calculations are summarized in the following table:

Process	W_{on}, kJ	Q_{in}, kJ	$\Delta E_{\text{int}}\left(= Q_{\text{in}} + W_{\text{on}}\right)$, kJ
1→2	0	3.74	3.74
2→3	−4.99	12.5	7.5
3→4	0	−7.48	−7.48
4→1	2.49	−6.24	−3.75

(*b*) The efficiency of the cycle is given by:

$$\varepsilon = \frac{W_{\text{by}}}{Q_{\text{in}}} = \frac{-W_{23} + (-W_{41})}{Q_{12} + Q_{23}}$$

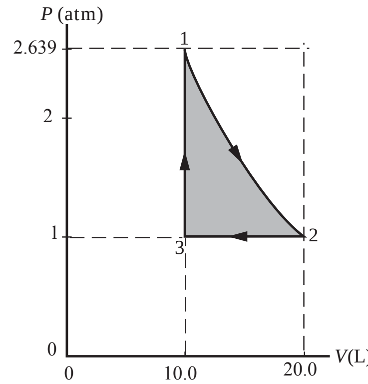
Substitute numerical values and evaluate ε:

$$\varepsilon = \frac{4.99\,\text{kJ} - 2.49\,\text{kJ}}{3.74\,\text{kJ} + 12.5\,\text{kJ}} \approx \boxed{15\%}$$

Remarks: Note that the work done per cycle is the area bounded by the rectangular path. Note also that, as expected because the system returns to its initial state, the sum of the changes in the internal energy for the cycle is zero.

32 •• The working substance of an engine is 1.00 mol of a diatomic ideal gas. The engine operates in a cycle consisting of three steps: (1) an adiabatic expansion from an initial volume of 10.0 L to a pressure of 1.00 atm and a volume of 20.0 L, (2) a compression at constant pressure to its original volume of 10.0 L, and (3) heating at constant volume to its original pressure. Find the efficiency of this cycle.

Picture the Problem The three steps in the process are shown on the *PV* diagram. We can find the efficiency of the cycle by finding the work done by the gas and the heat that enters the system per cycle.



The pressures and volumes at the end points of the adiabatic expansion are related according to:

$$P_1V_1^\gamma = P_2V_2^\gamma \Rightarrow P_1 = \left(\frac{V_2}{V_1}\right)^\gamma P_2$$

Substitute numerical values and evaluate P_1:

$$P_1 = \left(\frac{20.0\text{ L}}{10.0\text{ L}}\right)^{1.4}(1.00\text{ atm}) = 2.639\text{ atm}$$

Express the efficiency of the cycle:

$$\varepsilon = \frac{W}{Q_\text{h}} \qquad (1)$$

No heat enters or leaves the system during the adiabatic expansion:

$$Q_{12} = 0$$

Find the heat entering or leaving the system during the isobaric compression:

$$\begin{aligned} Q_{23} &= C_\text{P}\Delta T_{23} = \tfrac{7}{2}R\Delta T_{23} = \tfrac{7}{2}P\Delta V_{23} \\ &= \tfrac{7}{2}(1.00\,\text{atm})(10.0\,\text{L} - 20.0\,\text{L}) \\ &= -35.0\,\text{atm}\cdot\text{L} \end{aligned}$$

Find the heat entering or leaving the system during the constant-volume process:

$$\begin{aligned} Q_{31} &= C_\text{V}\Delta T_{31} = \tfrac{5}{2}R\Delta T_{31} = \tfrac{5}{2}\Delta PV_{31} \\ &= \tfrac{5}{2}(2.639\,\text{atm} - 1.00\,\text{atm})(10.0\,\text{L}) \\ &= 41.0\,\text{atm}\cdot\text{L} \end{aligned}$$

Apply the 1st law of thermodynamics to the cycle ($\Delta E_\text{int, cycle} = 0$) to obtain:

$$\begin{aligned} W_\text{on} &= \Delta E_\text{int} - Q_\text{in} = -Q_\text{in} \\ &= Q_{12} + Q_{23} + Q_{31} \\ &= 0 - 35.0\,\text{atm}\cdot\text{L} + 41.0\,\text{atm}\cdot\text{L} \\ &= 6.0\,\text{atm}\cdot\text{L} \end{aligned}$$

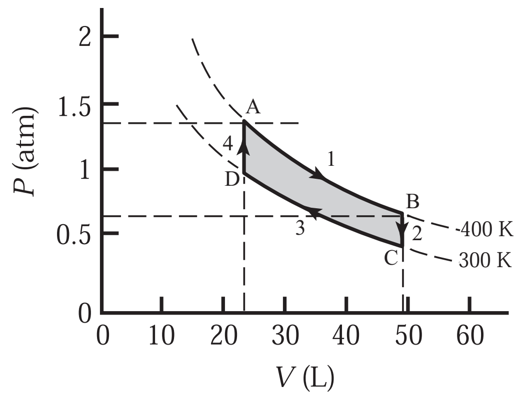
Substitute numerical values in equation (1) and evaluate ε:

$$\varepsilon = \frac{6.0\,\text{atm}\cdot\text{L}}{41\,\text{atm}\cdot\text{L}} = \boxed{15\%}$$

33 •• An engine using 1.00 mol of an ideal gas initially at a volume of 24.6 L and a temperature of 400 K performs a cycle consisting of four steps: (1) an isothermal expansion at 400 K to twice its initial volume, (2) cooling at constant volume to a temperature of 300 K (3) an isothermal compression to its original volume, and (4) heating at constant volume to its original temperature of 400 K. Assume that C_v = 21.0 J/K. Sketch the cycle on a *PV* diagram and find its efficiency.

Picture the Problem We can find the efficiency of the cycle by finding the work done by the gas and the heat that enters the system per cycle.

The *PV* diagram of the cycle is shown to the right. A, B, C, and D identify the four states of the gas and the numerals 1, 2, 3, and 4 represent the four steps through which the gas is taken.



Express the efficiency of the cycle:

$$\varepsilon = \frac{W}{Q_h} = \frac{W_1 + W_2 + W_3 + W_4}{Q_{h,1} + Q_{h,2} + Q_{h,3} + Q_{h,4}}$$

Because steps 2 and 4 are constant-volume processes, $W_2 = W_4 = 0$:

$$\varepsilon = \frac{W}{Q_h} = \frac{W_1 + 0 + W_3 + 0}{Q_{h,1} + Q_{h,2} + Q_{h,3} + Q_{h,4}}$$

Because the internal energy of the gas increases in step 4 while no work is done, and because the internal energy does not change during step 1 while work is done by the gas, heat enters the system only during these processes:

$$\varepsilon = \frac{W}{Q_h} = \frac{W_1 + W_3}{Q_{h,1} + Q_{h,4}} \qquad (1)$$

The work done during the isothermal expansion (1) is given by:

$$W_1 = nRT \ln\left(\frac{V_B}{V_A}\right)$$

The work done during the isothermal compression (3) is given by:

$$W_3 = nRT_c \ln\left(\frac{V_D}{V_C}\right)$$

Because there is no change in the internal energy of the system during step 1, the heat that enters the system during this isothermal expansion is given by:

$$Q_1 = W_1 = nRT_h \ln\left(\frac{V_B}{V_A}\right)$$

The heat that enters the system during the constant-volume step 4 is given by:

$$Q_4 = C_V \Delta T = C_V (T_h - T_c)$$

Substituting in equation (1) yields:

$$\varepsilon = \frac{nRT_h \ln\left(\frac{V_B}{V_A}\right) + nRT_c \ln\left(\frac{V_D}{V_C}\right)}{nRT_h \ln\left(\frac{V_B}{V_A}\right) + C_V (T_h - T_c)}$$

Noting the $\frac{V_B}{V_A} = 2$ and $\frac{V_D}{V_C} = \frac{1}{2}$, substitute and simplify to obtain:

$$\varepsilon = \frac{T_h \ln(2) + T_c \ln\left(\frac{1}{2}\right)}{T_h \ln(2) + \frac{C_V}{nR}(T_h - T_c)} = \frac{T_h \ln(2) - T_c \ln(2)}{T_h \ln(2) + \frac{C_V}{nR}(T_h - T_c)} = \frac{T_h - T_c}{T_h + \frac{C_V}{nR\ln(2)}(T_h - T_c)}$$

Substitute numerical values and evaluate ε:

$$\varepsilon = \frac{400\text{ K} - 300\text{ K}}{400\text{ K} + \frac{21.0\,\frac{\text{J}}{\text{K}}}{(1.00\text{ mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)\ln(2)}(400\text{ K} - 300\text{ K})} = \boxed{13.1\%}$$

34 •• Figure 19-15 shows the cycle followed by 1.00 mol of an ideal monatomic gas initially at a volume of 25.0 L. All the processes are quasi-static. Determine (*a*) the temperature of each numbered state of the cycle, (*b*) the heat transfer for each part of the cycle, and (*c*) the efficiency of the cycle.

Picture the Problem We can use the ideal-gas law to find the temperatures of each state of the gas and the heat capacities at constant volume and constant pressure to find the heat flow for the constant-volume and isobaric processes. Because the change in internal energy is zero for the isothermal process, we can use the expression for the work done on or by a gas during an isothermal process

to find the heat flow during such a process. Finally, we can find the efficiency of the cycle from its definition.

(*a*) Use the ideal-gas law to find the temperature at point 1:

$$T_1 = \frac{P_1V_1}{nR} = \frac{(100\,\text{kPa})(25.0\,\text{L})}{(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)} = \boxed{301\,\text{K}}$$

Use the ideal-gas law to find the temperatures at points 2 and 3:

$$T_2 = T_3 = \frac{P_2V_2}{nR} = \frac{(200\,\text{kPa})(25.0\,\text{L})}{(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)} = \boxed{601\,\text{K}}$$

(*b*) Find the heat entering the system for the constant-volume process from $1 \to 2$:

$$Q_{12} = C_V\Delta T_{12} = \tfrac{3}{2}R\Delta T_{12} = \tfrac{3}{2}\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(601\,\text{K} - 301\,\text{K}) = \boxed{3.74\,\text{kJ}}$$

Find the heat entering or leaving the system for the isothermal process from $2 \to 3$:

$$Q_{23} = nRT_2\ln\left(\frac{V_3}{V_2}\right) = (1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(601\,\text{K})\ln\left(\frac{50.0\,\text{L}}{25.0\,\text{L}}\right) = \boxed{3.46\,\text{kJ}}$$

Find the heat leaving the system during the isobaric compression from $3 \to 1$:

$$Q_{31} = C_P\Delta T_{31} = \tfrac{5}{2}R\Delta T_{31} = \tfrac{5}{2}\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(301\,\text{K} - 601\,\text{K}) = \boxed{-6.24\,\text{kJ}}$$

(*c*) Express the efficiency of the cycle:

$$\varepsilon = \frac{W}{Q_{\text{in}}} = \frac{W}{Q_{12} + Q_{23}} \qquad (1)$$

Apply the 1st law of thermodynamics to the cycle:

$$W = \sum Q = Q_{12} + Q_{23} + Q_{31} = 3.74\,\text{kJ} + 3.46\,\text{kJ} - 6.24\,\text{kJ} = 0.96\,\text{kJ}$$

because, for the cycle, $\Delta E_{\text{int}} = 0$.

Substitute numerical values in equation (1) and evaluate ε:

$$\varepsilon = \frac{0.96\,\text{kJ}}{3.74\,\text{kJ} + 3.46\,\text{kJ}} = \boxed{13\%}$$

35 •• An ideal diatomic gas follows the cycle shown in Figure 19-16. The temperature of state 1 is 200 K. Determine (*a*) the temperatures of the other three numbered states of the cycle and (*b*) the efficiency of the cycle.

Picture the Problem We can use the ideal-gas law to find the temperatures of each state of the gas. We can find the efficiency of the cycle from its definition; using the area enclosed by the cycle to find the work done per cycle and the heat entering the system between states 1 and 2 and 2 and 3 to determine Q_{in}.

(*a*) Use the ideal-gas law for a fixed amount of gas to find the temperature in state 2 to the temperature in state 1:

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \Rightarrow T_2 = T_1\frac{P_2V_2}{P_1V_1} = T_1\frac{P_2}{P_1}$$

Substitute numerical values and evaluate T_2:

$$T_2 = (200\,\text{K})\frac{(3.0\,\text{atm})}{(1.0\,\text{atm})} = \boxed{600\,\text{K}}$$

Apply the ideal-gas law for a fixed amount of gas to states 2 and 3 to obtain:

$$T_3 = T_2\frac{P_3V_3}{P_2V_2} = T_2\frac{V_3}{V_2}$$

Substitute numerical values and evaluate T_3:

$$T_3 = (600\,\text{K})\frac{(300\,\text{L})}{(100\,\text{L})} = \boxed{1800\,\text{K}}$$

Apply the ideal-gas law for a fixed amount of gas to states 3 and 4 to obtain:

$$T_4 = T_3\frac{P_4V_4}{P_3V_3} = T_3\frac{P_4}{P_3}$$

Substitute numerical values and evaluate T_4:

$$T_4 = (1800\,\text{K})\frac{(1.0\,\text{atm})}{(3.0\,\text{atm})} = \boxed{600\,\text{K}}$$

(*b*) The efficiency of the cycle is:

$$\varepsilon = \frac{W}{Q_{\text{in}}} \qquad (1)$$

Use the area of the rectangle to find the work done each cycle:

$$\begin{aligned} W &= \Delta P\Delta V \\ &= (300\,\text{L} - 100\,\text{L})(3.0\,\text{atm} - 1.0\,\text{atm}) \\ &= 400\,\text{atm}\cdot\text{L} \end{aligned}$$

Apply the ideal-gas law to state 1 to find the product of n and R:

$$nR = \frac{P_1V_1}{T_1} = \frac{(1.0\,\text{atm})(100\,\text{L})}{200\,\text{K}} = 0.50\,\text{L}\cdot\text{atm/K}$$

Noting that heat enters the system between states 1 and 2 and states 2 and 3, express Q_{in}:

$$Q_{\text{in}} = Q_{12} + Q_{23} = C_V\Delta T_{12} + C_P\Delta T_{23} = \tfrac{5}{2}nR\Delta T_{12} + \tfrac{7}{2}nR\Delta T_{23} = \left(\tfrac{5}{2}\Delta T_{12} + \tfrac{7}{2}\Delta T_{23}\right)nR$$

Substitute numerical values and evaluate Q_{in}:

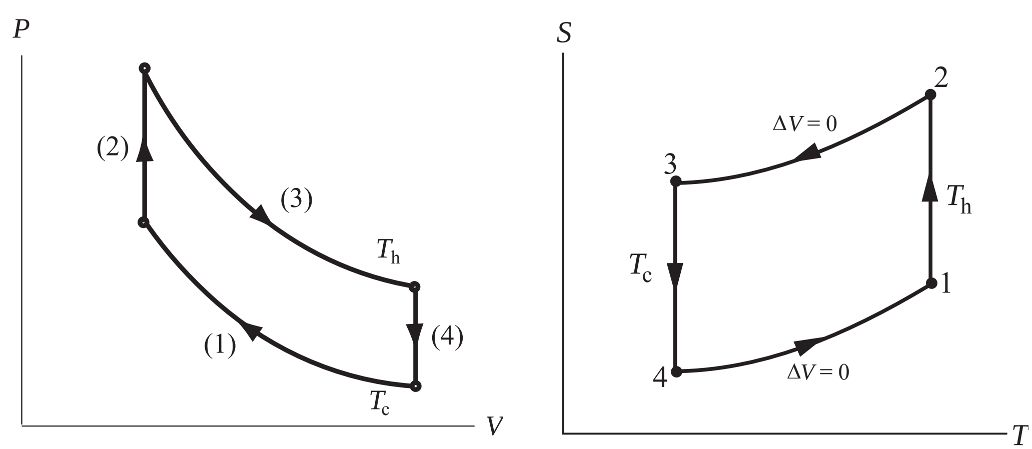
$$Q_{\text{in}} = \left[\tfrac{5}{2}(600\,\text{K} - 200\,\text{K}) + \tfrac{7}{2}(1800\,\text{K} - 600\,\text{K})\right]\left(0.50\frac{\text{L}\cdot\text{atm}}{\text{K}}\right) = 2600\,\text{atm}\cdot\text{L}$$

Substitute numerical values in equation (1) and evaluate ε:

$$\varepsilon = \frac{400\,\text{atm}\cdot\text{L}}{2600\,\text{atm}\cdot\text{L}} = \boxed{15\%}$$

36 ••• Recently, an old design for a heat engine, known as the *Stirling engine* has been promoted as a means of producing power from solar energy. The cycle of a Stirling engine is as follows: (1) isothermal compression of the working gas (2) heating of the gas at constant volume, (3) an isothermal expansion of the gas, and (4) cooling of the gas at constant volume. (*a*) Sketch *PV* and *ST* diagrams for the Stirling cycle. (*b*) Find the entropy change of the gas for each step of the cycle and show that the sum of these entropy changes is equal to zero.

Picture the Problem (*a*) The *PV* and *ST* cycles are shown below. (*b*) We can show that the entropy change during one Stirling cycle is zero by adding up the entropy changes for the four processes.



(*b*) The change in entropy for one Stirling cycle is the sum of the entropy changes during the cycle:

$$\Delta S_{\text{cycle}} = \Delta S_{12} + \Delta S_{23} + \Delta S_{34} + \Delta S_{41} \quad (1)$$

Express the entropy change for the isothermal process from state 1 to state 2:

$$\Delta S_{12} = nR\ln\left(\frac{V_2}{V_1}\right)$$

Similarly, the entropy change for the isothermal process from state 3 to state 4 is:

$$\Delta S_{34} = nR\ln\left(\frac{V_4}{V_3}\right)$$

or, because $V_2 = V_3$ and $V_1 = V_4$,

$$\Delta S_{34} = nR\ln\left(\frac{V_1}{V_2}\right) = -nR\ln\left(\frac{V_2}{V_1}\right)$$

The change in entropy for a constant-volume process is given by:

$$\Delta S_{\text{isochoric}} = \int\frac{dQ}{T} = \int_{T_\text{i}}^{T_\text{f}}\frac{nC_\text{V}dT}{T}$$

$$= nC_\text{V}\ln\left(\frac{T_\text{f}}{T_\text{i}}\right)$$

For the constant-volume process from state 2 to state 3:

$$\Delta S_{23} = C_\text{V}\ln\left(\frac{T_\text{c}}{T_\text{h}}\right)$$

For the constant-volume process from state 4 to state 1:

$$\Delta S_{41} = C_\text{V}\ln\left(\frac{T_\text{h}}{T_\text{c}}\right) = -C_\text{V}\ln\left(\frac{T_\text{c}}{T_\text{h}}\right)$$

Substituting in equation (1) yields:

$$\Delta S_{\text{cycle}} = nR\ln\left(\frac{V_2}{V_1}\right) + C_\text{V}\ln\left(\frac{T_\text{c}}{T_\text{h}}\right) - nR\ln\left(\frac{V_2}{V_1}\right) - C_\text{V}\ln\left(\frac{T_\text{c}}{T_\text{h}}\right) = \boxed{0}$$

37 •• ″As far as we know, Nature has never evolved a heat engine″—Steven Vogel, *Life's Devices*, Princeton University Press (1988). (*a*) Calculate the efficiency of a heat engine operating between body temperature (98.6ºF) and a typical outdoor temperature (70ºF), and compare this to the human body's efficiency for converting chemical energy into work (approximately 20%). Does this efficiency comparison contradict the second law of thermodynamics?
(*b*) From the result of Part (*a*), and a general knowledge of the conditions under which most warm-blooded organisms exist, give a reason why no warm-blooded organisms have evolved heat engines to increase their internal energies.

Picture the Problem We can use the efficiency of a Carnot engine operating between reservoirs at body temperature and typical outdoor temperatures to find an upper limit on the efficiency of an engine operating between these temperatures.

(*a*) Express the maximum efficiency of an engine operating between body temperature and 70°F:

$$\varepsilon_C = 1 - \frac{T_c}{T_h}$$

Use $T = \frac{5}{9}(t_F - 32) + 273$ to obtain:

$$T_{body} = 310\ \text{K} \text{ and } T_{room} = 294\ \text{K}$$

Substitute numerical values and evaluate ε_C:

$$\varepsilon_C = 1 - \frac{294\,\text{K}}{310\,\text{K}} = \boxed{5.16\%}$$

The fact that this efficiency is considerably less than the actual efficiency of a human body does not contradict the second law of thermodynamics. The application of the second law to chemical reactions such as the ones that supply the body with energy have not been discussed in the text but we can note that we don't get our energy from heat swapping between our body and the environment. Rather, we eat food to get the energy that we need.

(*b*) Most warm-blooded animals survive under roughly the same conditions as humans. To make a heat engine work with appreciable efficiency, internal body temperatures would have to be maintained at an unreasonably high level.

38 ••• The *diesel cycle* shown in Figure 19-17 approximates the behavior of a diesel engine. Process *ab* is an adiabatic compression, process *bc* is an expansion at constant pressure, process *cd* is an adiabatic expansion, and process *da* is cooling at constant volume. Find the efficiency of this cycle in terms of the volumes V_a, V_b and V_c.

Picture the Problem The working fluid will be modeled as an ideal gas and the process will be modeled as quasistatic. To find the efficiency of the diesel cycle we can find the heat that enters the system and the heat that leaves the system and use the expression that gives the efficiency in terms of these quantities. Note that no heat enters or leaves the system during the adiabatic processes *ab* and *cd.* Heat enters the system during the isobaric process *bc* and leaves the system during the isovolumetric process *da.*

Express the efficiency of the cycle in terms of Q_c and Q_h:

$$\varepsilon = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h}$$

Express Q for the isobaric warming process *bc*:

$$Q_{bc} = Q_h = C_P(T_c - T_b)$$

Because C_V is independent of T, Q_{da} (the constant-volume cooling process) is given by:

$$Q_{da} = Q_c = C_V(T_d - T_a)$$

Substitute for Q_h and Q_c and simplify using $\gamma = C_P/C_V$ to obtain:

$$\varepsilon = 1 - \frac{C_V(T_d - T_a)}{C_P(T_c - T_b)} = 1 - \frac{(T_d - T_a)}{\gamma(T_c - T_b)}$$

Using an equation for a quasistatic adiabatic process, relate the temperatures T_a and T_b to the volumes V_a and V_b:

$$T_a V_a^{\gamma-1} = T_b V_b^{\gamma-1} \Rightarrow T_a = T_b \frac{V_b^{\gamma-1}}{V_a^{\gamma-1}} \quad (1)$$

Proceeding similarly, relate the temperatures T_c and T_d to the volumes V_c and V_d:

$$T_c V_c^{\gamma-1} = T_d V_d^{\gamma-1} \Rightarrow T_d = T_c \frac{V_c^{\gamma-1}}{V_d^{\gamma-1}} \quad (2)$$

Use equations (1) and (2) to eliminate T_a and T_d:

$$\varepsilon = 1 - \frac{\left(T_c \frac{V_c^{\gamma-1}}{V_d^{\gamma-1}} - T_b \frac{V_b^{\gamma-1}}{V_a^{\gamma-1}}\right)}{\gamma(T_c - T_b)}$$

Because $V_a = V_d$:

$$\varepsilon = 1 - \frac{\left(\left(\frac{V_c}{V_a}\right)^{\gamma-1} - \frac{T_b}{T_c}\left(\frac{V_b}{V_a}\right)^{\gamma-1}\right)}{\gamma\left(1 - \frac{T_b}{T_c}\right)}$$

Noting that $P_b = P_c$, apply the ideal-gas law to relate T_b and T_c:

$$\frac{T_b}{T_c} = \frac{V_b}{V_c}$$

Substitute for the ratio of T_b to T_c and simplify to obtain:

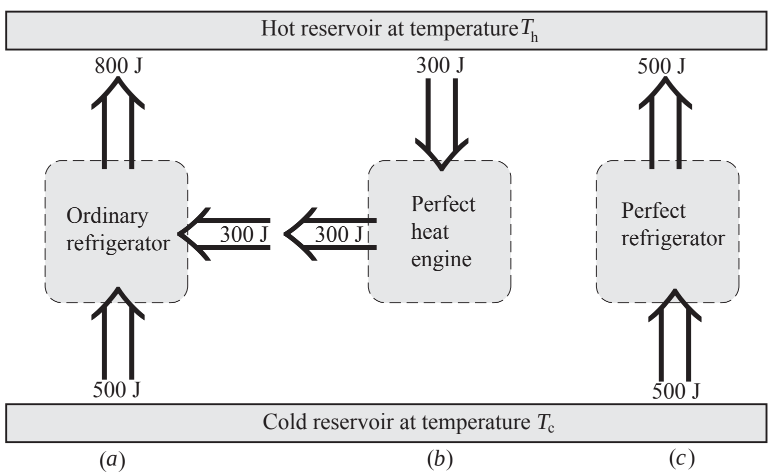
$$\varepsilon = 1 - \frac{\left(\frac{V_c}{V_a}\right)^{\gamma-1} - \frac{V_b}{V_c}\left(\frac{V_b}{V_a}\right)^{\gamma-1}}{\gamma\left(1 - \frac{V_b}{V_c}\right)} \cdot \frac{\frac{V_c}{V_a}}{\frac{V_c}{V_a}} = 1 - \frac{\left(\frac{V_c}{V_a}\right)^{\gamma-1} - \frac{V_b}{V_c}\left(\frac{V_b}{V_a}\right)^{\gamma-1}}{\gamma\left(\frac{V_c}{V_a} - \frac{V_b}{V_a}\right)}$$

$$= 1 - \frac{\left(\frac{V_c}{V_a}\right)^{\gamma} - \left(\frac{V_b}{V_a}\right)^{\gamma}}{\gamma\left(\frac{V_c}{V_a} - \frac{V_b}{V_a}\right)} = \boxed{1 - \frac{V_c^{\gamma} - V_b^{\gamma}}{\gamma V_a^{\gamma-1}(V_c - V_b)}}$$

Second Law of Thermodynamics

39 •• [SSM] A refrigerator absorbs 500 J of heat from a cold reservoir and releases 800 J to a hot reservoir. Assume that the heat-engine statement of the second law of thermodynamics is false, and show how a perfect engine working with this refrigerator can violate the refrigerator statement of the second law of thermodynamics.

Determine the Concept The following diagram shows an ordinary refrigerator that uses 300 J of work to remove 500 J of heat from a cold reservoir and releases 800 J of heat to a hot reservoir (see (*a*) in the diagram). Suppose the heat-engine statement of the second law is false. Then a ″perfect″ heat engine could remove energy from the hot reservoir and convert it completely into work with 100 percent efficiency. We could use this perfect heat engine to remove 300 J of energy from the hot reservoir and do 300 J of work on the ordinary refrigerator (see (*b*) in the diagram). Then, the combination of the perfect heat engine and the ordinary refrigerator would be a perfect refrigerator; transferring 500 J of heat from the cold reservoir to the hot reservoir without requiring any work (see (*c*) in the diagram).This violates the refrigerator statement of the second law.



40 •• If two curves that represent quasi-static adiabatic processes could intersect on a *PV* diagram, a cycle could be completed by an isothermal path between the two adiabatic curves shown in Figure 19-18. Show that such a cycle violates the second law of thermodynamics.

Determine the Concept The work done by the system is the area enclosed by the cycle, where we assume that we start with the isothermal expansion. It is only in this expansion that heat is extracted from a reservoir. There is no heat transfer in the adiabatic expansion or compression. Thus, we would completely convert heat to mechanical energy, without exhausting any heat to a cold reservoir, in violation of the second law of thermodynamics.

Carnot Cycles

41 • [SSM] A Carnot engine works between two heat reservoirs at temperatures T_h = 300 K and T_c = 200 K. (*a*) What is its efficiency? (*b*) If it absorbs 100 J of heat from the hot reservoir during each cycle, how much work does it do each cycle? (*c*) How much heat does it release during each cycle? (*d*) What is the COP of this engine when it works as a refrigerator between the same two reservoirs?

Picture the Problem We can find the efficiency of the Carnot engine using $\varepsilon = 1 - T_c / T_h$ and the work done per cycle from $\varepsilon = W / Q_h$. We can apply conservation of energy to find the heat rejected each cycle from the heat absorbed and the work done each cycle. We can find the COP of the engine working as a refrigerator from its definition.

(*a*) The efficiency of the Carnot engine depends on the temperatures of the hot and cold reservoirs:

$$\varepsilon_C = 1 - \frac{T_c}{T_h} = 1 - \frac{200\,\text{K}}{300\,\text{K}} = \boxed{33.3\%}$$

(*b*) Using the definition of efficiency, relate the work done each cycle to the heat absorbed from the hot reservoir:

$$W = \varepsilon_C Q_h = (0.333)(100\,\text{J}) = \boxed{33.3\,\text{J}}$$

(*c*) Apply conservation of energy to relate the heat given off each cycle to the heat absorbed and the work done:

$$Q_c = Q_h - W = 100\,\text{J} - 33.3\,\text{J} = 66.7\,\text{J}$$
$$= \boxed{67\,\text{J}}$$

(*d*) Using its definition, express and evaluate the refrigerator's coefficient of performance:

$$\text{COP} = \frac{Q_c}{W} = \frac{66.7\,\text{J}}{33.3\,\text{J}} = \boxed{2.0}$$

42 • An engine absorbs 250 J of heat per cycle from a reservoir at 300 K and releases 200 J of heat per cycle to a reservoir at 200 K. (*a*) What is its efficiency? (*b*) How much additional work per cycle could be done if the engine were reversible?

Picture the Problem We can find the efficiency of the engine from its definition and the additional work done if the engine were reversible from $W = \varepsilon_C Q_h$, where ε_C is the Carnot efficiency.

(*a*) Express the efficiency of the engine in terms of the heat absorbed from the high-temperature reservoir and the heat exhausted to the low-temperature reservoir:

$$\varepsilon = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h}$$
$$= 1 - \frac{200\,\text{J}}{250\,\text{J}} = \boxed{20.0\%}$$

(*b*) Express the additional work done if the engine is reversible:

$$\Delta W = W_{\text{Carnot}} - W_{\text{Part}(a)} \qquad (1)$$

Relate the work done by a reversible engine to its Carnot efficiency:

$$W = \varepsilon_C Q_h = \left(1 - \frac{T_c}{T_h}\right) Q_h$$

Substitute numerical values and evaluate *W*:

$$W = \left(1 - \frac{200\,\text{K}}{300\,\text{K}}\right)(250\,\text{J}) = 83.3\,\text{J}$$

Substitute numerical values in equation (1) and evaluate Δ*W*:

$$\Delta W = 83.3\,\text{J} - 50\,\text{J} = \boxed{33\,\text{J}}$$

43 •• A reversible engine working between two reservoirs at temperatures T_h and T_c has an efficiency of 30%. Working as a heat engine, it releases 140 J per cycle of heat to the cold reservoir. A second engine working between the same two reservoirs also releases 140 J per cycle to the cold reservoir. Show that if the second engine has an efficiency greater than 30%, the two engines working together would violate the heat-engine statement of the second law.

Determine the Concept Let the first engine be run as a refrigerator. Then it will remove 140 J from the cold reservoir, deliver 200 J to the hot reservoir, and require 60 J of energy to operate. Now take the second engine and run it between the same reservoirs, and let it eject 140 J into the cold reservoir, thus replacing the heat removed by the refrigerator. If ε_2, the efficiency of this engine, is greater than 30%, then Q_{h2}, the heat removed from the hot reservoir by this engine, is 140 J/$(1 - \varepsilon_2)$ > 200 J, and the work done by this engine is $W = \varepsilon_2 Q_{h2} > 60$ J. The end result of all this is that the second engine can run the refrigerator, replacing the heat taken from the cold reservoir, and do additional mechanical work. The two systems working together then convert heat into mechanical energy without rejecting any heat to a cold reservoir, in violation of the second law.

44 •• A reversible engine working between two reservoirs at temperatures T_h and T_c has an efficiency of 20%. Working as a heat engine, it does 100 J of work per cycle. A second engine working between the same two reservoirs also does 100 J of work per cycle. Show that if the efficiency of the second engine is greater

than 20%, the two engines working together would violate the refrigerator statement of the second law.

Determine the Concept If the reversible engine is run as a refrigerator, it will require 100 J of mechanical energy to take 400 J of heat from the cold reservoir and deliver 500 J to the hot reservoir. Now let the second engine, with $\varepsilon_2 > 0.2$, operate between the same two heat reservoirs and use it to drive the refrigerator. Because $\varepsilon_2 > 0.2$, this engine will remove less than 500 J from the hot reservoir in the process of doing 100 J of work. The net result is then that no net work is done by the two systems working together, but a finite amount of heat is transferred from the cold reservoir to the hot reservoir, in violation of the refrigerator statement of the second law.

45 •• A Carnot engine works between two heat reservoirs as a refrigerator. During each cycle, 100 J of heat are absorbed and 150 J are released to the hot reservoir. (*a*) What is the efficiency of the Carnot engine when it works as a heat engine between the same two reservoirs? (*b*) Show that no other engine working as a refrigerator between the same two reservoirs can have a COP greater than 2.00.

Picture the Problem We can use the definition of efficiency to find the efficiency of the Carnot engine operating between the two reservoirs.

(*a*) The efficiency of the Carnot engine is given by:

$$\varepsilon_C = \frac{W}{Q_h} = \frac{50\,\text{J}}{150\,\text{J}} = \boxed{33\%}$$

(*b*) If the COP > 2, then 50 J of work will remove more than 100 J of heat from the cold reservoir and put more than 150 J of heat into the hot reservoir. So running the engine described in Part (*a*) to operate the refrigerator with a COP > 2 will result in the transfer of heat from the cold to the hot reservoir without doing any net mechanical work in violation of the second law.

46 •• A Carnot engine works between two heat reservoirs at temperatures $T_h = 300$ K and $T_c = 77.0$ K. (*a*) What is its efficiency? (*b*) If it absorbs 100 J of heat from the hot reservoir during each cycle, how much work does it do? (*c*) How much heat does it release to the low-temperature reservoir during each cycle? (*d*) What is the coefficient of performance of this engine when it works as a refrigerator between these two reservoirs?

Picture the Problem We can use the definitions of the efficiency of a Carnot engine and the coefficient of performance of a refrigerator to find these quantities. The work done each cycle by the Carnot engine is given by $W = \varepsilon_C Q_h$ and we can use the conservation of energy to find the heat rejected to the low-temperature reservoir.

(*a*) The efficiency of a Carnot engine depends on the temperatures of the hot and cold reservoirs:

$$\varepsilon_C = 1 - \frac{T_c}{T_h} = 1 - \frac{77.0\,\text{K}}{300\,\text{K}} = \boxed{74.3\%}$$

(*b*) Express the work done each cycle in terms of the efficiency of the engine and the heat absorbed from the high-temperature reservoir:

$$W = \varepsilon_C Q_h = (0.743)(100\,\text{J}) = \boxed{74.3\,\text{J}}$$

(*c*) Apply conservation of energy to obtain:

$$Q_c = Q_h - W = 100\,\text{J} - 74.3\,\text{J} = \boxed{26\,\text{J}}$$

(*d*) Using its definition, express and evaluate the refrigerator's coefficient of performance:

$$\text{COP} = \frac{Q_c}{W} = \frac{26\,\text{J}}{74.3\,\text{J}} = \boxed{0.35}$$

47 •• **[SSM]** In the cycle shown in Figure 19-19, 1.00 mol of an ideal diatomic gas is initially at a pressure of 1.00 atm and a temperature of 0.0ºC. The gas is heated at constant volume to T_2 = 150ºC and is then expanded adiabatically until its pressure is again 1.00 atm. It is then compressed at constant pressure back to its original state. Find (*a*) the temperature after the adiabatic expansion, (*b*) the heat absorbed or released by the system during each step, (*c*) the efficiency of this cycle, and (*d*) the efficiency of a Carnot cycle operating between the temperature extremes of this cycle.

Picture the Problem We can use the ideal-gas law for a fixed amount of gas and the equations of state for an adiabatic process to find the temperatures, volumes, and pressures at the end points of each process in the given cycle. We can use $Q = C_V \Delta T$ and $Q = C_P \Delta T$ to find the heat entering and leaving during the constant-volume and isobaric processes and the first law of thermodynamics to find the work done each cycle. Once we've calculated these quantities, we can use its definition to find the efficiency of the cycle and the definition of the Carnot efficiency to find the efficiency of a Carnot engine operating between the extreme temperatures.

(*a*) Apply the ideal-gas law for a fixed amount of gas to relate the temperature at point 3 to the temperature at point 1:

$$\frac{P_1V_1}{T_1}=\frac{P_3V_3}{T_3}$$

or, because $P_1 = P_3$,

$$T_3=T_1\frac{V_3}{V_1} \qquad (1)$$

Apply the ideal-gas law for a fixed amount of gas to relate the pressure at point 2 to the temperatures at points 1 and 2 and the pressure at 1:

$$\frac{P_1V_1}{T_1}=\frac{P_2V_2}{T_2}\Rightarrow P_2=\frac{P_1V_1T_2}{V_2T_1}$$

Because $V_1 = V_2$:

$$P_2=P_1\frac{T_2}{T_1}=(1.00\,\text{atm})\frac{423\,\text{K}}{273\,\text{K}}=1.55\,\text{atm}$$

Apply an equation for an adiabatic process to relate the pressures and volumes at points 2 and 3:

$$P_1V_1^{\gamma}=P_3V_3^{\gamma}\Rightarrow V_3=V_1\left(\frac{P_1}{P_3}\right)^{\frac{1}{\gamma}}$$

Noting that V_1 = 22.4 L, evaluate V_3:

$$V_3=(22.4\,\text{L})\left(\frac{1.55\,\text{atm}}{1\,\text{atm}}\right)^{\frac{1}{1.4}}=30.6\,\text{L}$$

Substitute numerical values in equation (1) and evaluate T_3 and t_3:

$$T_3=(273\,\text{K})\frac{30.6\,\text{L}}{22.4\,\text{L}}=373\,\text{K}$$

and

$$t_3=T_3-273=\boxed{100°\text{C}}$$

(*b*) Process 1→2 takes place at constant volume (note that γ = 1.4 corresponds to a diatomic gas and that $C_P - C_V = R$):

$$Q_{12}=C_V\Delta T_{12}=\tfrac{5}{2}R\Delta T_{12}$$
$$=\tfrac{5}{2}\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(423\,\text{K}-273\,\text{K})$$
$$=\boxed{3.12\,\text{kJ}}$$

Process 2→3 takes place adiabatically:

$$Q_{23}=\boxed{0}$$

Process 3→1 is isobaric (note that $C_P = C_V + R$):

$$Q_{31}=C_P\Delta T_{31}=\tfrac{7}{2}R\Delta T_{12}$$
$$=\tfrac{7}{2}\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(273\,\text{K}-373\,\text{K})$$
$$=\boxed{-2.91\,\text{kJ}}$$

(*c*) The efficiency of the cycle is given by:

$$\varepsilon = \frac{W}{Q_{in}} \quad (2)$$

Apply the first law of thermodynamics to the cycle:

$\Delta E_{int} = Q_{in} + W_{on}$
or, because $\Delta E_{int,\,cycle} = 0$ (the system begins and ends in the same state) and $W_{on} = -W_{by\ the\ gas} = Q_{in}$.

Evaluating *W* yields:

$$W = \sum Q = Q_{12} + Q_{23} + Q_{31} = 3.12\,kJ + 0 - 2.91\,kJ = 0.21\,kJ$$

Substitute numerical values in equation (2) and evaluate ε:

$$\varepsilon = \frac{0.21\,kJ}{3.12\,kJ} = \boxed{6.7\%}$$

(*d*) Express and evaluate the efficiency of a Carnot cycle operating between 423 K and 273 K:

$$\varepsilon_C = 1 - \frac{T_c}{T_h} = 1 - \frac{273\,K}{423\,K} = \boxed{35.5\%}$$

48 •• You are part of a team that is completing a mechanical-engineering project. Your team built a steam engine that takes in superheated steam at 270ºC and discharges condensed steam from its cylinder at 50.0ºC. Your team has measured its efficiency to be 30.0%. (*a*) How does this efficiency compare with the maximum possible efficiency for your engine? (*b*) If the useful power output of the engine is known to be 200 kW, how much heat does the engine release to its surroundings in 1.00 h?

Picture the Problem We can find the maximum efficiency of the steam engine by calculating the Carnot efficiency of an engine operating between the given temperatures. We can apply the definition of efficiency to find the heat discharged to the engine's surroundings in 1.00 h.

(*a*) The efficiency of the steam engine as a percentage of the maximum possible efficiency is given by:

$$\frac{\varepsilon_{steam\,engine}}{\varepsilon_{max}} = \frac{0.300}{\varepsilon_{max}}$$

The efficiency of a Carnot engine operating between temperatures F_c and T_h is:

$$\varepsilon_{max} = 1 - \frac{T_c}{T_h} = 1 - \frac{323\,K}{543\,K} = 40.52\%$$

Substituting for ε_{max} yields:

$$\frac{\varepsilon_{\text{steam engine}}}{\varepsilon_{max}} = \frac{0.300}{0.4052} = 74.05\%$$

or

$$\varepsilon_{\text{steam engine}} = \boxed{0.740\varepsilon_{max}}$$

(*b*) Relate the heat Q_c discharged to the engine's surroundings to Q_h and the efficiency of the engine:

$$\varepsilon = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} \Rightarrow Q_c = (1-\varepsilon)Q_h$$

Using its definition, relate the efficiency of the engine to the heat intake of the engine and the work it does each cycle:

$$Q_h = \frac{W}{\varepsilon} = \frac{P\Delta t}{\varepsilon}$$

Substitute for Q_h in the expression for $\boldsymbol{Q}_c$ and simplify to obtain:

$$Q_c = (1-\varepsilon)\frac{P\Delta t}{\varepsilon} = \left(\frac{1}{\varepsilon} - 1\right)P\Delta t$$

Substitute numerical values and evaluate $Q_c(1.00\text{ h})$:

$$Q_c(1.00\text{ h}) = \left(\frac{1}{0.300} - 1\right)\left(200\frac{\text{kJ}}{\text{s}}\right)(3600\text{ s}) = \boxed{1.68\text{ GJ}}$$

*Heat Pumps

49 • **[SSM]** As an engineer, you are designing a heat pump that is capable of delivering heat at the rate of 20 kW to a house. The house is located where, in January, the average outside temperature is –10ºC. The temperature of the air in the air handler inside the house is to be 40ºC. (*a*) What is maximum possible COP for a heat pump operating between these temperatures? (*b*) What must the minimum power of the electric motor driving the heat pump be? (*c*) In reality, the COP of the heat pump will be only 60 percent of the ideal value. What is the minimum power of the electric motor when the COP is 60 percent of the ideal value?

Picture the Problem We can use the definition of the COP_{HP} and the Carnot efficiency of an engine to express the maximum efficiency of the refrigerator in terms of the reservoir temperatures. We can apply the definition of power to find the minimum power needed to run the heat pump.

(*a*) Express the COP_{HP} in terms of T_h and T_c:

$$COP_{HP} = \frac{Q_h}{W} = \frac{Q_h}{Q_h - Q_c}$$
$$= \frac{1}{1-\frac{Q_c}{Q_h}} = \frac{1}{1-\frac{T_c}{T_h}} = \frac{T_h}{T_h - T_c}$$

Substitute numerical values and evaluate COP_{HP}:

$$COP_{HP} = \frac{313\,\text{K}}{313\,\text{K} - 263\,\text{K}} = 6.26$$
$$= \boxed{6.3}$$

(*b*) The COP_{HP} is also given by:

$$COP_{HP} = \frac{P_{out}}{P_{motor}} \Rightarrow P_{motor} = \frac{P_{out}}{COP_{HP}}$$

Substitute numerical values and evaluate P_{motor}:

$$P_{motor} = \frac{20\,\text{kW}}{6.26} = \boxed{3.2\,\text{kW}}$$

(*c*) The minimum power of the electric motor is given by:

$$P_{min} = \frac{\frac{dQ_c}{dt}}{\varepsilon_{HP}} = \frac{\frac{dQ_c}{dt}}{\varepsilon\left(COP_{HP,max}\right)}$$

where ε_{HP} is the efficiency of the heat pump.

Substitute numerical values and evaluate P_{min}:

$$P_{min} = \frac{20\,\text{kW}}{(0.60)(6.26)} = \boxed{5.3\,\text{kW}}$$

50 • A refrigerator is rated at 370 W. (*a*) What is the maximum amount of heat it can absorb from the food compartment in 1.00 min if the food-compartment temperature of the refrigerator is 0.0ºC and it releases heat into a room at 20.0ºC? (*b*) If the COP of the refrigerator is 70% of that of a reversible refrigerator, how much heat can it absorb from the food compartment in 1.00 min under these conditions?

Picture the Problem We can use the definition of the COP to relate the heat removed from the refrigerator to its power rating and operating time. By expressing the COP in terms of T_c and T_h we can write the amount of heat removed from the refrigerator as a function of T_c, T_h, P, and Δt.

(*a*) Express the amount of heat the refrigerator can remove in a given period of time as a function of its COP:

$$Q_c = (COP)W$$
$$= (COP)P\Delta t$$

Express the COP in terms of T_h and T_c and simplify to obtain:

$$\text{COP} = \frac{Q_c}{W} = \frac{Q_c}{\varepsilon Q_h} = \frac{Q_h - W}{\varepsilon Q_h} = \frac{1-\varepsilon}{\varepsilon} = \frac{1}{\varepsilon} - 1 = \frac{1}{1-\frac{T_c}{T_h}} - 1 = \frac{T_c}{T_h - T_c}$$

Substituting for COP yields:

$$Q_c = \left(\frac{T_c}{T_h - T_c}\right)P\Delta t$$

Substitute numerical values and evaluate Q_c:

$$Q_c = \left(\frac{273\ \text{K}}{293\ \text{K} - 273\ \text{K}}\right)(370\ \text{W})\left(1.00\ \text{min} \times \frac{60\ \text{s}}{\text{min}}\right) = 303\ \text{kJ} = \boxed{0.30\ \text{MJ}}$$

(*b*) If the COP is 70% of the efficiency of an ideal pump:

$$Q_c^{'} = (0.70)(303\ \text{kJ}) = \boxed{0.21\ \text{MJ}}$$

51 • A refrigerator is rated at 370 W. (*a*) What is the maximum amount of heat it can absorb for the food compartment in 1.00 min if the temperature in the compartment is 0.0ºC and it releases heat into a room at 35ºC? (*b*) If the COP of the refrigerator is 70% of that of a reversible pump, how much heat can it absorb from the food compartment in 1.00 min? Is the COP for the refrigerator greater when the temperature of the room is 35ºC or 20ºC? Explain.

Picture the Problem We can use the definition of the COP to relate the heat removed from the refrigerator to its power rating and operating time. By expressing the COP in terms of T_c and T_h we can write the amount of heat removed from the refrigerator as a function of T_c, T_h, P, and Δt.

(*a*) Express the amount of heat the refrigerator can remove in a given period of time as a function of its COP:

$$Q_c = (\text{COP})W = (\text{COP})P\Delta t$$

Express the COP in terms of T_h and T_c and simplify to obtain:

$$\text{COP} = \frac{Q_c}{W} = \frac{Q_c}{\varepsilon Q_h} = \frac{Q_h - W}{\varepsilon Q_h} = \frac{1-\varepsilon}{\varepsilon} = \frac{1}{\varepsilon} - 1 = \frac{1}{1-\dfrac{T_c}{T_h}} - 1 = \frac{T_c}{T_h - T_c}$$

Substituting for COP yields:

$$Q_c = \left(\frac{T_c}{T_h - T_c}\right) P\Delta t$$

Substitute numerical values and evaluate Q_c:

$$Q_c = \left(\frac{273\ \text{K}}{308\ \text{K} - 273\ \text{K}}\right)(370\ \text{W})\left(1.00\ \text{min} \times \frac{60\ \text{s}}{\text{min}}\right) = 173\ \text{kJ} = \boxed{0.17\ \text{MJ}}$$

(*b*) If the COP is 70% of the efficiency of an ideal pump:

$$Q_c' = (0.70)(173\ \text{kJ}) = \boxed{0.12\ \text{MJ}}$$

Because the temperature difference increases when the room is warmer, the COP decreases.

52 ••• You are installing a heat pump, whose COP is half the COP of a reversible heat pump. You will use the pump on chilly winter nights to increase the air temperature in your bedroom. Your bedroom's dimensions are 5.00 m × 3.50 m × 2.50 m. The air temperature should increase from 63°F to 68°F. The outside temperature is 35°F, and the temperature at the air handler in the room is 112°F. If the pump's electric power consumption is 750 W, how long will you have to wait in order for the room's air to warm (take the specific heat of air to be 1.005 kJ/(kg·°C)? Assume you have good window draperies and good wall insulation so that you can neglect the release of heat through windows, walls, ceilings and floors. Also assume that the heat capacity of the floor, ceiling, walls and furniture are negligible.

Picture the Problem We can use the definition of the coefficient of performance of a heat pump and the relationship between the work done per cycle and the pump's power consumption to find your waiting time.

The coefficient of performance of the heat pump is defined as:

$$\mathrm{COP_{HP}} = \frac{Q_h}{W} = \frac{Q_h}{P\Delta t} \Rightarrow \Delta t = \frac{Q_h}{(\mathrm{COP_{HP}})P}$$

where Q_h is the heat required to raise the temperature of your bedroom, P is the power consumption of the heat pump, and Δt is the time required to warm the bedroom.

We're given that the coefficient of performance of the heat pump is half the coefficient of performance of an ideal heat pump:

$$\mathrm{COP_{HP}} = \frac{Q_h}{W} = \tfrac{1}{2}\mathrm{COP_{max}} = \tfrac{1}{2}\left(\frac{T_h}{T_h - T_c}\right)$$

Substituting for $\mathrm{COP_{HP}}$ yields:

$$\Delta t = \frac{2Q_h}{\left(\frac{T_h}{T_h - T_c}\right)P}$$

The heat required to warm the room is related to the volume of the room, the density of air, and the desired increase in temperature:

$$Q_h = mc\Delta T = \rho Vc\Delta T$$

where ρ is the density of air and c is its specific heat capacity.

Substitute for Q_h to obtain:

$$\Delta t = \frac{2\rho Vc\Delta T}{\left(\frac{T_h}{T_h - T_c}\right)P}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2\left(1.293\,\frac{\mathrm{kg}}{\mathrm{m}^3}\right)(5.00\ \mathrm{m}\times 3.50\ \mathrm{m}\times 2.50\ \mathrm{m})\left(1005\,\frac{\mathrm{J}}{\mathrm{kg\cdot C^\circ}}\right)\left(5\ \mathrm{F^\circ}\times\frac{5\ \mathrm{C^\circ}}{9\ \mathrm{F^\circ}}\right)}{\left(\frac{317\ \mathrm{K}}{317\ \mathrm{K} - 275\ \mathrm{K}}\right)(750\ \mathrm{W})} = \boxed{56\ \mathrm{s}}$$

Entropy Changes

53 • **[SSM]** You inadvertently leave a pan of water boiling away on the hot stove. You return just in time to see the last drop converted into steam. The pan originally held 1.00 L of boiling water. What is the change in entropy of the water associated with its change of state from liquid to gas?

Picture the Problem Because the water absorbed heat in the vaporization process its change in entropy is positive and given by $\Delta S_{H_2O} = \frac{Q_{\substack{\text{absorbed}\\ \text{by } H_2O}}}{T}$. See Table 18-2 for the latent heat of vaporization of water.

The change in entropy of the water is given by:

$$\Delta S_{H_2O} = \frac{Q_{\substack{\text{absorbed}\\ \text{by } H_2O}}}{T}$$

The heat absorbed by the water as it vaporizes is the product of its mass and latent heat of vaporization:

$$Q_{\substack{\text{absorbed}\\ \text{by } H_2O}} = mL_v = \rho V L_v$$

Substituting for $Q_{\substack{\text{absorbed}\\ \text{by } H_2O}}$ yields:

$$\Delta S_{H_2O} = \frac{\rho V L_v}{T}$$

Substitute numerical values and evaluate $\Delta \boldsymbol{S}_{H_2O}$:

$$\Delta S_{H_2O} = \frac{\left(1.00\,\frac{\text{kg}}{\text{L}}\right)(1.00\text{ L})\left(2257\,\frac{\text{kJ}}{\text{kg}}\right)}{373\text{ K}} = \boxed{6.05\,\frac{\text{kJ}}{\text{K}}}$$

54 • What is the change in entropy of 1.00 mol of liquid water at 0.0ºC that freezes to ice at 0.0°C?

Picture the Problem We can use the definition of entropy change to find the change in entropy of the liquid water as it freezes. Because heat is removed from liquid water when it freezes, the change in entropy of the liquid water is negative. See Appendix C for the molar mass of water and Table 18-2 for the latent heat of fusion of water.

The change in entropy of the water is given by::

$$\Delta S_{H_2O} = \frac{Q_{\substack{\text{removed}\\ \text{from } H_2O}}}{T}$$

The heat removed from the water as it freezes is the product of its mass and latent heat of fusion:

$$Q_{\substack{\text{removed}\\ \text{from } H_2O}} = -mL_f$$

or, because $m = nM_{H_2O}$,

$$Q_{\substack{\text{removed}\\ \text{from } H_2O}} = -nM_{H_2O}L_f$$

Substitute numerical values and evaluate ΔS_{H_2O}:

$$\Delta S_{H_2O} = \frac{-(1.00\,\text{mol})\left(18.015\,\frac{\text{g}}{\text{mol}}\right)\left(333.5\,\frac{\text{J}}{\text{g}}\right)}{273\,\text{K}} = \boxed{-22.0\,\frac{\text{J}}{\text{K}}}$$

55 •• Consider the freezing of 50.0 g of water once it is placed in the freezer compartment of a refrigerator. Assume the walls of the freezer are maintained at –10ºC. The water, initially liquid at 0.0ºC, is frozen into ice and cooled to –10ºC. Show that even though the entropy of the water decreases, the net entropy of the universe increases.

Picture the Problem The change in the entropy of the universe resulting from the freezing of this water and the cooling of the ice formed is the sum of the entropy changes of the water-ice and the freezer. Note that, while the entropy of the water decreases, the entropy of the freezer increases.

The change in entropy of the universe resulting from this freezing and cooling process is given by:

$$\Delta S_u = \Delta S_{\text{water}} + \Delta S_{\text{freezer}} \quad (1)$$

Express ΔS_{water}:

$$\Delta S_{\text{water}} = \Delta S_{\text{freezing}} + \Delta S_{\text{cooling}} \quad (2)$$

Express $\Delta S_{\text{freezing}}$:

$$\Delta S_{\text{freezing}} = \frac{-Q_{\text{freezing}}}{T_{\text{freezing}}} \quad (3)$$

where the minus sign is a consequence of the fact that energy is leaving the water as it freezes.

Relate Q_{freezing} to the latent heat of fusion and the mass of the water:

$$Q_{\text{freezing}} = mL_f$$

Substitute in equation (3) to obtain:

$$\Delta S_{\text{freezing}} = \frac{-mL_f}{T_{\text{freezing}}}$$

Express $\Delta S_{\text{cooling}}$:

$$\Delta S_{\text{cooling}} = mC_p \ln\left(\frac{T_f}{T_i}\right)$$

Substitute in equation (2) to obtain:

$$\Delta S_{\text{water}} = \frac{-mL_f}{T_{\text{freezing}}} + mC_p \ln\left(\frac{T_f}{T_i}\right)$$

Noting that the freezer gains heat (at 263 K) from the freezing water and cooling ice, express $\Delta S_{\text{freezer}}$:

$$\Delta S_{\text{freezer}} = \frac{\Delta Q_{\text{ice}}}{T_{\text{freezer}}} + \frac{\Delta Q_{\text{cooling ice}}}{T_{\text{freezer}}} = \frac{mL_{\text{f}}}{T_{\text{freezer}}} + \frac{mC_{\text{p}}\Delta T}{T_{\text{freezer}}}$$

Substitute for ΔS_{water} and $\Delta S_{\text{freezer}}$ in equation (1):

$$\Delta S_{\text{u}} = \frac{-mL_{\text{f}}}{T_{\text{freezing}}} + mC_{\text{p}}\ln\left(\frac{T_{\text{f}}}{T_{\text{i}}}\right) + \frac{mL_{\text{f}}}{T_{\text{freezer}}} + \frac{mC_{\text{p}}\Delta T}{T_{\text{freezer}}} = m\left[\frac{-L_{\text{f}}}{T_{\text{freezing}}} + C_{\text{p}}\ln\left(\frac{T_{\text{f}}}{T_{\text{i}}}\right) + \frac{L_{\text{f}} + C_{\text{p}}\Delta T}{T_{\text{freezer}}}\right]$$

Substitute numerical values and evaluate ΔS_{u}:

$$\Delta S_{\text{u}} = (0.0500\,\text{kg})\left[-\frac{333.5\times10^{3}\,\frac{\text{J}}{\text{kg}}}{273\,\text{K}} + \left(2100\frac{\text{J}}{\text{kg}\cdot\text{K}}\right)\ln\left(\frac{263\,\text{K}}{273\,\text{K}}\right) + \frac{333.5\times10^{3}\,\frac{\text{J}}{\text{kg}} + \left(2100\frac{\text{J}}{\text{kg}\cdot\text{K}}\right)(273\,\text{K} - 263\,\text{K})}{263\,\text{K}}\right] = \boxed{2.40\,\text{J/K}}$$

and, because $\Delta S_{\text{u}} > 0$, the entropy of the universe increases.

56 • In this problem, 2.00 mol of an ideal gas at 400 K expand quasi-statically and isothermally from an initial volume of 40.0 L to a final volume of 80.0 L. (*a*) What is the entropy change of the gas? (*b*) What is the entropy change of the universe for this process?

Picture the Problem We can use the definition of entropy change and the 1st law of thermodynamics to express ΔS for the ideal gas as a function of its initial and final volumes.

(*a*) The entropy change of the gas is given by:

$$\Delta S_{\text{gas}} = \frac{Q}{T} \qquad (1)$$

Apply the first law of thermodynamics to the isothermal process to express Q in terms of W_{on}:

$$Q = \Delta E_{int} - W_{on}$$

or, because $\Delta E_{int} = 0$ for an isothermal expansion of a gas,

$$Q = -W_{on}$$

The work done on the gas is given by:

$$W_{on} = nRT\ln\left(\frac{V_i}{V_f}\right) \Rightarrow Q = -nRT\ln\left(\frac{V_i}{V_f}\right)$$

Substitute for Q in equation (1) to obtain:

$$\Delta S_{gas} = -nR\ln\left(\frac{V_i}{V_f}\right)$$

Substitute numerical values and evaluate ΔS:

$$\Delta S_{gas} = -(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)\ln\left(\frac{40.0\,\text{L}}{80.0\,\text{L}}\right) = \boxed{11.5\frac{\text{J}}{\text{K}}}$$

(b) Because the process is reversible:

$$\Delta S_u = \boxed{0}$$

Remarks: The entropy change of the environment of the gas is −11.5 J/K.

57 •• [SSM] A system completes a cycle consisting of six quasi-static steps, during which the total work done by the system is 100 J. During step 1 the system absorbs 300 J of heat from a reservoir at 300 K, during step 3 the system absorbs 200 J of heat from a reservoir at 400 K, and during step 5 it absorbs heat from a reservoir at temperature T_3. (During steps 2, 4 and 6 the system undergoes adiabatic processes in which the temperature of the system changes from one reservoir's temperature to that of the next.) (a) What is the entropy change of the system for the complete cycle? (b) If the cycle is reversible, what is the temperature T_3?

Picture the Problem We can use the fact that the system *returns to its original state* to find the entropy change for the complete cycle. Because the entropy change for the complete cycle is the sum of the entropy changes for each process, we can find the temperature T_3 from the entropy changes during the 1st two processes and the heat released during the third.

(a) Because S is a state function of the system, and because the system's final state is identical to its initial state:

$$\Delta S_{\substack{\text{system}\\ \text{1 complete cycle}}} = \boxed{0}$$

(*b*) Relate the entropy changes for each of the three heat reservoirs and the system for one complete cycle of the system:

$$\Delta S_1 + \Delta S_2 + \Delta S_3 + \Delta S_{\text{system}} = 0$$

or

$$\frac{Q_1}{T_1} + \frac{Q_2}{T_2} + \frac{Q_3}{T_3} + 0 = 0$$

Substitute numerical values. Heat is rejected by the two high-temperature reservoirs and absorbed by the cold reservoir:

$$\frac{-300\,\text{J}}{300\,\text{K}} + \frac{-200\,\text{J}}{400\,\text{K}} + \frac{400\,\text{J}}{T_3} = 0$$

Solving for T_3 yields:

$$T_3 = \boxed{267\,\text{K}}$$

58 •• In this problem, 2.00 mol of an ideal gas initially has a temperature of 400 K and a volume of 40.0 L. The gas undergoes a free adiabatic expansion to twice its initial volume. What is (*a*) the entropy change of the gas and (*b*) the entropy change of the universe?

Picture the Problem The initial and final temperatures are the same for a free expansion of an ideal gas. Thus, the entropy change ΔS for a free expansion from V_i to V_f is the same as ΔS for an isothermal process from V_i to V_f. We can use the definition of entropy change and the 1st law of thermodynamics to express ΔS for the ideal gas as a function of its initial and final volumes.

(*a*) The entropy change of the gas is given by:

$$\Delta S_{\text{gas}} = \frac{Q}{T} \qquad (1)$$

Apply the first law of thermodynamics to the isothermal process to express Q:

$$Q = \Delta E_{\text{int}} - W_{\text{on}}$$

or, because $\Delta E_{\text{int}} = 0$ for a free expansion of a gas,

$$Q = -W_{\text{on}}$$

The work done on the gas is given by:

$$W_{\text{on}} = nRT\ln\left(\frac{V_\text{i}}{V_\text{f}}\right) \Rightarrow Q = -nRT\ln\left(\frac{V_\text{i}}{V_\text{f}}\right)$$

Substitute for Q in equation (1) to obtain:

$$\Delta S_{\text{gas}} = -nR\ln\left(\frac{V_\text{i}}{V_\text{f}}\right)$$

Substitute numerical values and evaluate ΔS:

$$\Delta S_{\text{gas}} = -(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)\ln\left(\frac{40.0\,\text{L}}{80.0\,\text{L}}\right) = \boxed{11.5\frac{\text{J}}{\text{K}}}$$

(*b*) The change in entropy of the universe is the sum of the entropy changes of the gas and the surroundings:

$$\Delta S_{\text{u}} = \Delta S_{\text{gas}} + \Delta S_{\text{surroundings}}$$

For the change in entropy of the surroundings we use the fact that, during the free expansion, the surroundings are unaffected:

$$\Delta S_{\text{surroundings}} = \frac{Q_{\text{rev}}}{T} = \frac{0}{T} = 0$$

The change in entropy of the universe is the change in entropy of the gas:

$$\Delta S_{\text{u}} = \boxed{11.5\,\frac{\text{J}}{\text{K}}}$$

59 •• A 200-kg block of ice at 0.0ºC is placed in a large lake. The temperature of the lake is just slightly higher than 0.0ºC, and the ice melts very slowly. (*a*) What is the entropy change of the ice? (*b*) What is the entropy change of the lake? (*c*) What is the entropy change of the universe (the ice plus the lake)?

Picture the Problem Because the ice gains heat as it melts, its entropy change is positive and can be calculated from its definition. Because the temperature of the lake is just slightly greater than 0°C and the mass of water is so much greater than that of the block of ice, the absolute value of the entropy change of the lake will be approximately equal to the entropy change of the ice as it melts.

(*a*) The entropy change of the ice is given by:

$$\Delta S_{\text{ice}} = \frac{mL_{\text{f}}}{T}$$

Substitute numerical values and evaluate ΔS_{ice}:

$$\Delta S_{\text{ice}} = \frac{(200\,\text{kg})\left(333.5\,\frac{\text{kJ}}{\text{kg}}\right)}{273\,\text{K}} = \boxed{244\,\frac{\text{kJ}}{\text{K}}}$$

(*b*) Relate the entropy change of the lake to the entropy change of the ice:

$$\Delta S_{\text{lake}} \approx -\Delta S_{\text{ice}} = \boxed{-244\,\frac{\text{kJ}}{\text{K}}}$$

(*c*) The entropy change of the universe due to this melting process is the sum of the entropy changes of the ice and the lake:

$$\Delta S_{\text{u}} = \Delta S_{\text{ice}} + \Delta S_{\text{lake}}$$

Because the temperature of the lake is slightly greater than that of the ice, the magnitude of the entropy change of the lake is less than 244 kJ/K and the entropy change of the universe is just slightly greater than zero. The melting of the ice is an irreversible process and $\boxed{\Delta S_u > 0}$.

60 •• A 100-g piece of ice at 0.0ºC is placed in an insulated calorimeter with negligible heat capacity containing 100 g of water at 100ºC. (*a*) What is the final temperature of the water once thermal equilibrium is established? (*b*) Find the entropy change of the universe for this process.

Picture the Problem We can use conservation of energy to find the equilibrium temperature of the water and apply the equations for the entropy change during a melting process and for constant-pressure processes to find the entropy change of the universe (the entropy change of the piece of ice plus the entropy change of the water in the insulated container).

(*a*) Apply conservation of energy to obtain:

$$\sum_i Q_i = 0$$

or

$$Q_{\substack{\text{melting}\\\text{ice}}} + Q_{\substack{\text{warming}\\\text{water}}} - Q_{\substack{\text{cooling}\\\text{water}}} = 0$$

Substitute to relate the masses of the ice and water to their temperatures, specific heats, and the final temperature of the water:

$$(100\,\text{g})\left(333.5\,\frac{\text{kJ}}{\text{kg}}\right) + (100\,\text{g})\left(4.18\,\frac{\text{kJ}}{\text{kg}\cdot\text{C}^\circ}\right)t - (100\,\text{g})\left(4.18\,\frac{\text{kJ}}{\text{kg}\cdot\text{C}^\circ}\right)(100^\circ\text{C} - t) = 0$$

Solving for t yields:

$$t = \boxed{10.1^\circ\text{C}}$$

(*b*) The entropy change of the universe is the sum of the entropy changes of the ice and the water:

$$\Delta S_u = \Delta S_{\text{ice}} + \Delta S_{\text{water}}$$

Using the expression for the entropy change for a constant-pressure process, express the entropy change of the melting ice and warming ice-water:

$$\Delta S_{\text{ice}} = \Delta S_{\text{melting ice}} + \Delta S_{\text{warming water}} = \frac{mL_f}{T_f} + mc_P \ln\left(\frac{T_f}{T_i}\right)$$

Substitute numerical values to obtain:

$$\Delta S_{\text{ice}} = \frac{(0.100\,\text{kg})\left(333.5\,\frac{\text{kJ}}{\text{kg}}\right)}{273\,\text{K}} + (0.100\,\text{kg})\left(4.18\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\ln\left(\frac{283\,\text{K}}{273\,\text{K}}\right) = 137\,\frac{\text{J}}{\text{K}}$$

Find the entropy change of the cooling water:

$$\Delta S_{\text{water}} = (0.100\,\text{kg})\left(4.18\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\ln\left(\frac{283\,\text{K}}{373\,\text{K}}\right) = -115\,\frac{\text{J}}{\text{K}}$$

Substitute for ΔS_{ice} and ΔS_{water} and evaluate the entropy change of the universe:

$$\Delta S_{\text{u}} = 137\,\frac{\text{J}}{\text{K}} - 115\,\frac{\text{J}}{\text{K}} = \boxed{22\,\frac{\text{J}}{\text{K}}}$$

Remarks: The result that $\Delta S_{\text{u}} > 0$ tells us that this process is irreversible.

61 •• [SSM] A 1.00-kg block of copper at 100ºC is placed in an insulated calorimeter of negligible heat capacity containing 4.00 L of liquid water at 0.0ºC. Find the entropy change of (*a*) the copper block, (*b*) the water, and (*c*) the universe.

Picture the Problem We can use conservation of energy to find the equilibrium temperature of the water and apply the equations for the entropy change during a constant pressure process to find the entropy changes of the copper block, the water, and the universe.

(*a*) Use the equation for the entropy change during a constant-pressure process to express the entropy change of the copper block:

$$\Delta S_{\text{Cu}} = m_{\text{Cu}} c_{\text{Cu}} \ln\left(\frac{T_{\text{f}}}{T_{\text{i}}}\right) \qquad (1)$$

Apply conservation of energy to obtain:

$$\sum_{\text{i}} Q_{\text{i}} = 0$$

or

$$Q_{\substack{\text{copper}\\\text{block}}} + Q_{\substack{\text{warming}\\\text{water}}} = 0$$

Substitute to relate the masses of the block and water to their temperatures, specific heats, and the final temperature T_f of the water:

$$(1.00\,\text{kg})\left(0.386\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(T_f - 373\,\text{K}) + (4.00\,\text{L})\left(1.00\frac{\text{kg}}{\text{L}}\right)\left(4.18\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(T_f - 273\,\text{K}) = 0$$

Solve for T_f to obtain: $T_f = 275.26\,\text{K}$

Substitute numerical values in equation (1) and evaluate ΔS_{Cu}:

$$\Delta S_{\text{Cu}} = (1.00\,\text{kg})\left(0.386\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\ln\left(\frac{275.26\,\text{K}}{373\,\text{K}}\right) = \boxed{-117\frac{\text{J}}{\text{K}}}$$

(*b*) The entropy change of the water is given by:

$$\Delta S_{\text{water}} = m_{\text{water}}c_{\text{water}}\ln\left(\frac{T_f}{T_i}\right)$$

Substitute numerical values and evaluate ΔS_{water}:

$$\Delta S_{\text{water}} = (4.00\,\text{kg})\left(4.18\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\ln\left(\frac{275.26\,\text{K}}{273\,\text{K}}\right) = \boxed{138\frac{\text{J}}{\text{K}}}$$

(*c*) Substitute for ΔS_{Cu} and ΔS_{water} and evaluate the entropy change of the universe:

$$\Delta S_u = \Delta S_{\text{Cu}} + \Delta S_{\text{water}} = -117\frac{\text{J}}{\text{K}} + 138\frac{\text{J}}{\text{K}} = \boxed{21\frac{\text{J}}{\text{K}}}$$

Remarks: The result that $\Delta S_u > 0$ tells us that this process is irreversible.

62 •• If a 2.00-kg piece of lead at 100ºC is dropped into a lake at 10ºC, find the entropy change of the universe.

Picture the Problem Because the mass of the water in the lake is so much greater than the mass of the piece of lead, the temperature of the lake will increase only slightly and we can reasonably assume that its final temperature is 10°C. We can apply the equation for the entropy change during a constant pressure process to find the entropy changes of the piece of lead, the water in the lake, and the universe.

Express the entropy change of the universe in terms of the entropy changes of the lead and the water in the lake:

$$\Delta S_u = \Delta S_{Pb} + \Delta S_w \quad (1)$$

Using the equation for the entropy change during a constant-pressure process, express and evaluate the entropy change of the lead:

$$\Delta S_{Pb} = m_{Pb}c_{Pb}\ln\left(\frac{T_f}{T_i}\right) = (2.00\,\text{kg})\left(0.128\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)\ln\left(\frac{283\,\text{K}}{373\,\text{K}}\right) = -70.69\frac{\text{J}}{\text{K}}$$

The entropy change of the water in the lake is given by:

$$\Delta S_w = \frac{Q_w}{T_w} = \frac{Q_{Pb}}{T_w} = \frac{m_{Pb}c_{Pb}\Delta T_{Pb}}{T_w}$$

Substitute numerical values and evaluate ΔS_w:

$$\Delta S_w = \frac{(2.00\,\text{kg})\left(0.128\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(90\,\text{K})}{283\,\text{K}} = 81.41\,\text{J/K}$$

Substitute numerical values in equation (1) and evaluate ΔS_u:

$$\Delta S_u = -70.69\frac{\text{J}}{\text{K}} + 81.41\frac{\text{J}}{\text{K}} = \boxed{11\frac{\text{J}}{\text{K}}}$$

Entropy and ″Lost″ Work

63 •• **[SSM]** A a reservoir at 300 K absorbs 500 J of heat from a second reservoir at 400 K. (*a*) What is the change in entropy of the universe, and (*b*) how much work is lost during the process?

Picture the Problem We can find the entropy change of the universe from the entropy changes of the high- and low-temperature reservoirs. The maximum amount of the 500 J of heat that could be converted into work can be found from the maximum efficiency of an engine operating between the two reservoirs.

(*a*) The entropy change of the universe is the sum of the entropy changes of the two reservoirs:

$$\Delta S_u = \Delta S_h + \Delta S_c = -\frac{Q}{T_h} + \frac{Q}{T_c} = -Q\left(\frac{1}{T_h} - \frac{1}{T_c}\right)$$

Substitute numerical values and evaluate ΔS_u:

$$\Delta S_u = (-500\,\text{J})\left(\frac{1}{400\,\text{K}} - \frac{1}{300\,\text{K}}\right) = \boxed{0.42\,\text{J/K}}$$

(*b*) Relate the heat that could have been converted into work to the maximum efficiency of an engine operating between the two reservoirs:

$$W = \varepsilon_{\text{max}} Q_h$$

The maximum efficiency of an engine operating between the two reservoir temperatures is the efficiency of a Carnot device operating between the reservoir temperatures:

$$\varepsilon_{\text{max}} = \varepsilon_C = 1 - \frac{T_c}{T_h}$$

Substitute for ε_{max} to obtain:

$$W = \left(1 - \frac{T_c}{T_h}\right) Q_h$$

Substitute numerical values and evaluate W:

$$W = \left(1 - \frac{300\,\text{K}}{400\,\text{K}}\right)(500\,\text{J}) = \boxed{125\,\text{J}}$$

64 •• In this problem, 1.00 mol of an ideal gas at 300 K undergoes a free adiabatic expansion from $V_1 = 12.3$ L to $V_2 = 24.6$ L. It is then compressed isothermally and reversibly back to its original state. (*a*) What is the entropy change of the universe for the complete cycle? (*b*) How much work is lost in this cycle? (*c*) Show that the work lost is $T\Delta S_u$.

Picture the Problem Although no energy is lost by the gas in the adiabatic free expansion, the process is irreversible and the entropy of the gas (and the universe) increases. In the isothermal reversible process that returns the gas to its original state, the gas releases energy to the surroundings. However, because the process is reversible, the entropy change of the universe is zero. Consequently, the net entropy change is the negative of that of the gas in the isothermal compression.

(*a*) Relate the entropy change of the universe to the entropy changes of the gas during 1 complete cycle:

$$\Delta S_{\mathrm{u}} = \Delta S_{\substack{\text{gas during}\\ \text{free expansion}}} + \Delta S_{\substack{\text{gas during}\\ \text{isothermal compresion}}}$$

or, because $\Delta S_{\substack{\text{gas during}\\ \text{isothermal compression}}} = 0$,

$$\Delta S_{\mathrm{u}} = \Delta S_{\substack{\text{gas during}\\ \text{free expansion}}} = \frac{Q}{T}$$

The work done by the gas during its isothermal compression is given by:

$$W_{\text{by}} = -W_{\text{on}} = -Q = -nRT\ln\left(\frac{V_{\mathrm{f}}}{V_{\mathrm{i}}}\right)$$

Substituting for Q in the expression for ΔS_{u} and simplifying yields:

$$\Delta S_{\mathrm{u}} = -nR\ln\left(\frac{V_{\mathrm{f}}}{V_{\mathrm{i}}}\right) \qquad (1)$$

Substitute numerical values and evaluate ΔS_{u}:

$$\Delta S_{\mathrm{u}} = -(1.00\,\mathrm{mol})\left(8.314\frac{\mathrm{J}}{\mathrm{mol\cdot K}}\right)\ln\left(\frac{12.3\,\mathrm{L}}{24.6\,\mathrm{L}}\right) = 5.763\frac{\mathrm{J}}{\mathrm{K}} = \boxed{5.76\frac{\mathrm{J}}{\mathrm{K}}}$$

(*b*) Use Equation 19-22 to find the amount of energy that becomes unavailable for doing work during this process:

$$W_{\text{lost}} = T\Delta S_{\mathrm{u}} = (300\,\mathrm{K})\left(5.763\frac{\mathrm{J}}{\mathrm{K}}\right) = \boxed{1.73\,\mathrm{kJ}}$$

(*c*) No work is done in the free expansion. In the adiabatic compression, the work done on the gas is:

$$W_{\text{by gas, f}\to\text{i}} = -W_{\text{on gas, f}\to\text{i}} = -nRT\ln\left(\frac{V_{\mathrm{i}}}{V_{\mathrm{f}}}\right)$$

$$= nRT\ln\left(\frac{V_{\mathrm{f}}}{V_{\mathrm{i}}}\right) = T\left(nR\ln\left(\frac{V_{\mathrm{f}}}{V_{\mathrm{i}}}\right)\right)$$

$$= \boxed{T\Delta S_{\mathrm{u}}}$$

General Problems

65 • A heat engine with an output of 200 W has an efficiency of 30%. It operates at 10.0 cycles/s. (*a*) How much work is done by the engine during each cycle? (*b*) How much heat is absorbed from the hot reservoir and how much is released to the cold reservoir during each cycle?

Picture the Problem We can use the definition of power to find the work done each cycle and the definition of efficiency to find the heat that is absorbed each cycle. Application of the first law of thermodynamics will yield the heat given off each cycle.

(*a*) Use the definition of power to relate the work done in each cycle to the frequency of each cycle:

$$W_{\text{cycle}} = P\Delta t = \frac{P}{f}$$

where f is the frequency of the engine.

Substitute numerical values and evaluate W_{cycle}:

$$W_{\text{cycle}} = \frac{200\text{ W}}{10.0\text{ s}^{-1}} = \boxed{20.0\text{ J}}$$

(*b*) Express the heat absorbed in each cycle in terms of the work done and the efficiency of the engine:

$$Q_{\text{h,cycle}} = \frac{W_{\text{cycle}}}{\varepsilon} = \frac{20.0\text{ J}}{0.30} = \boxed{67\text{ J}}$$

Apply the 1st law of thermodynamics to find the heat given off in each cycle:

$$Q_{\text{c,cycle}} = Q_{\text{h,cycle}} - W = 67\text{ J} - 20\text{ J} = \boxed{47\text{ J}}$$

66 • During each cycle, a heat engine operating between two heat reservoirs absorbs 150 J from the reservoir at 100ºC and releases 125 J to the reservoir at 20ºC. (*a*) What is the efficiency of this engine? (*b*) What is the ratio of its efficiency to that of a Carnot engine working between the same reservoirs? (This ratio is called the *second law efficiency*.)

Picture the Problem We can use their definitions to find the efficiency of the engine and that of a Carnot engine operating between the same reservoirs.

(*a*) The efficiency of the engine is given by:

$$\varepsilon = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h}$$

Substitute numerical values and evaluate ε:

$$\varepsilon = 1 - \frac{125\text{ J}}{150\text{ J}} = 16.67\% = \boxed{16.7\%}$$

(*b*) Find the efficiency of a Carnot engine operating between the same reservoirs:

$$\varepsilon_C = 1 - \frac{T_c}{T_h} = 1 - \frac{293\text{ K}}{373\text{ K}} = 21.45\%$$

Express the ratio of the two efficiencies:

$$\frac{\varepsilon}{\varepsilon_C} = \frac{16.67\%}{21.45\%} = \boxed{0.777}$$

67 • **[SSM]** An engine absorbs 200 kJ of heat per cycle from a reservoir at 500 K and releases heat to a reservoir at 200 K. Its efficiency is 85 percent of that of a Carnot engine working between the same reservoirs. (*a*) What is the

efficiency of this engine? (*b*) How much work is done in each cycle? (*c*) How much heat is released to the low-temperature reservoir during each cycle?

Picture the Problem We can use the definition of efficiency to find the work done by the engine during each cycle and the first law of thermodynamics to find the heat released to the low-temperature reservoir during each cycle.

(*a*) Express the efficiency of the engine in terms of the efficiency of a Carnot engine working between the same reservoirs:

$$\varepsilon = 0.85\varepsilon_C = 0.85\left(1-\frac{T_c}{T_h}\right)$$

Substitute numerical values and evaluate ε:

$$\varepsilon = 0.85\left(1-\frac{200\,\text{K}}{500\,\text{K}}\right) = 0.510 = \boxed{51\%}$$

(*b*) Use the definition of efficiency to find the work done in each cycle:

$$W = \varepsilon Q_h = (0.510)(200\,\text{kJ}) = 102\text{ kJ} = \boxed{0.10\,\text{MJ}}$$

(*c*) Apply the first law of thermodynamics to the cycle to obtain:

$$Q_{c,\text{cycle}} = Q_{h,\text{cycle}} - W = 200\,\text{kJ} - 102\,\text{kJ} = \boxed{98\,\text{kJ}}$$

68 • Estimate the change in entropy of the universe associated with an Olympic diver diving into the water from the 10-m platform.

Picture the Problem Assume that the mass of the diver is 75 kg and that the temperature of the water in the pool is 25°C. The energy added to the water in the pool is the change in the gravitational potential energy of the diver during the dive.

The change in entropy of the universe associated with a dive is given by:

$$\Delta S_u = \Delta S_{\text{water}} = \frac{Q_{\text{added to water}}}{T_{\text{water}}}$$

where $Q_{\text{added to water}}$ is the energy entering the water as a result of the kinetic energy of the diver as he enters the water.

The energy added to the water is the change in the gravitational potential energy of the diver:

$$\Delta S_u = \frac{mgh}{T_{\text{water}}}$$

Substitute numerical values and evaluate ΔS_u:

$$\Delta S_u = \frac{(75\text{ kg})(9.81\text{ m/s}^2)(10\text{ m})}{(25+273)\text{K}} \approx \boxed{25\frac{\text{J}}{\text{K}}}$$

69 • To maintain the temperature inside a house at 20ºC, the electric power consumption of the electric baseboard heaters is 30.0 kW on a day when the outside temperature is –7ºC. At what rate does this house contribute to the increase in the entropy of the universe?

Picture the Problem The change in entropy of the universe is the change in entropy of the house plus the change in entropy of the environment. We can find the change in entropy of the house by exploiting the given information that the temperature inside the house is maintained at a constant temperature. We can find the change in entropy of the surrounding by dividing the heat added by the temperature.

Entropy is a state function, and the state of the house does not change. Therefore the entropy of the house does not change:

$$\Delta S_u = \Delta S_{\text{house}} + \Delta S_{\text{surroundings}}$$

or, because $\Delta S_{\text{house}} = 0$,

$$\Delta S_u = \Delta S_{\text{surroundings}}$$

Heat is absorbed by the surroundings at the same rate R that energy is delivered to the house:

$$\Delta S_{\text{surroundings}} = \frac{Q}{T_{\text{surroundings}}} = \frac{R\Delta t}{T_{\text{surroundings}}}$$

Substitute for $\Delta S_{\text{surroundings}}$ yields:

$$\Delta S_u = \frac{R\Delta t}{T_{\text{surroundings}}} \Rightarrow \frac{\Delta S_u}{\Delta t} = \frac{R}{T_{\text{surroundings}}}$$

Substitute numerical values and evaluate $\Delta S_u/\Delta t$:

$$\frac{\Delta S_u}{\Delta t} = \frac{30.0\text{ kW}}{266\text{ K}} = \boxed{113\frac{\text{W}}{\text{K}}}$$

70 •• Calvin Cliffs Nuclear Power Plant, located on the Hobbes River, generates 1.00 GW of power. In this plant, liquid sodium circulates between the reactor core and a heat exchanger located in the superheated steam that drives the turbine. Heat is absorbed by the liquid sodium in the core, and released by the liquid sodium (and into the superheated steam) in the heat exchanger. The temperature of the superheated steam is 500 K. Heat is released into the river, and the water in the river flows by at a temperature of 25ºC. (*a*) What is the highest efficiency that this plant can have? (*b*) How much heat is released into the river every second? (*c*) How much heat must be released by the core to supply

1.00 GW of electrical power? (*d*) Assume that new environmental laws have been passed to preserve the unique wildlife of the river. Because of these laws, the plant is not allowed to heat the river by more than 0.50ºC. What is the minimum flow rate that the water in the Hobbes River must have?

Picture the Problem We can use the expression for the Carnot efficiency of the plant to find the highest efficiency this plant can have. We can then use this efficiency to find the power that must be supplied to the plant to generate 1.00 GW of power and, from this value, the power that is wasted. The rate at which heat is being released to the river is related to the requisite flow rate of the river by $dQ/dt = c\Delta T\rho\, dV/dt$.

(*a*) The Carnot efficiency of a plant operating between temperatures T_c and T_h is given by:

$$\varepsilon_{max} = \varepsilon_C = 1 - \frac{T_c}{T_h}$$

Substitute numerical values and evaluate ε_C:

$$\varepsilon_{max} = 1 - \frac{298\,\text{K}}{500\,\text{K}} = \boxed{0.404}$$

(*c*) The power that must be supplied, at 40.4% efficiency, to produce an output of 1.00 GW is given by:

$$P_{supplied} = \frac{P_{output}}{\varepsilon_{max}} = \frac{1.00\,\text{GW}}{0.404} = \boxed{2.48\,\text{GW}}$$

(*b*) Relate the wasted power to the power generated and the power supplied:

$$P_{wasted} = P_{supplied} - P_{generated}$$

Substitute numerical values and evaluate P_{wasted}:

$$P_{wasted} = 2.48\,\text{GW} - 1.00\,\text{GW} = \boxed{1.48\,\text{GW}}$$

(*d*) Express the rate at which heat is being dumped into the river:

$$\frac{dQ}{dt} = c\Delta T\frac{dm}{dt} = c\Delta T\frac{d}{dt}(\rho V) = c\Delta T\rho\frac{dV}{dt}$$

Solve for the flow rate dV/dt of the river:

$$\frac{dV}{dt} = \frac{dQ/dt}{c\Delta T\rho}$$

Substitute numerical values (see Table 19-1 for the specific heat of water) and evaluate dV/dt:

$$\frac{dV}{dt} = \frac{1.48\times10^{9}\ \frac{\text{J}}{\text{s}}}{\left(4180\ \frac{\text{J}}{\text{kg}}\right)(0.50\ \text{K})\left(10^{3}\ \frac{\text{kg}}{\text{m}^{3}}\right)} = \boxed{7.1\times10^{5}\ \text{L/s}}$$

71 •• An inventor comes to you to explain his new invention. It is a novel heat engine using water vapor as the working substance. He claims that the water vapor absorbs heat at 100°C, does work at the rate of 125 W, and releases heat to the air at the rate of only 25.0 W, when the air temperature is 25°C. (*a*) Explain to him why he cannot be correct. (*b*) After careful analysis of the data in his prospectus folder, you decide he has made an error in the measurement of his exhausted-heat value. What is the minimum rate of exhausting heat that would make you consider believing him?

Picture the Problem We can use the inventor's data to calculate the thermal efficiency of his steam engine and then compare this value to the efficiency of a Carnot engine operating between the same temperatures.

(*a*) The Carnot efficiency of an engine operating between these temperatures is:

$$\varepsilon_{\text{C}} = 1 - \frac{T_{\text{c}}}{T_{\text{h}}} = 1 - \frac{298\ \text{K}}{373\ \text{K}} = 20.1\%$$

The thermal efficiency of the inventor's device, in terms of the rate at which it expels heat to the air and does work is:

$$\varepsilon = \frac{\frac{dW}{dt}}{\frac{dQ_{\text{h}}}{dt}} = \frac{\frac{dW}{dt}}{\frac{dW}{dt} + \frac{dQ_{\text{c}}}{dt}} = \frac{125\ \text{W}}{125\ \text{W} + 25.0\ \text{W}} = 83.3\%$$

You should explain to him that, because the efficiency he claims for his invention is greater than the efficiency of a Carnot engine operating between the same two temperatures, his data is not consistent with what is known about the thermodynamics of engines. He must have made a mistake in his analysis of his data–or he is a con man looking for suckers to swindle.

(*b*) The maximum efficiency of a steam engine that has ever been achieved is about 50% of the Carnot efficiency of an engine operating between the same temperatures.

Setting the efficiency of his steam engine equal to half the Carnot efficiency of the engine yields:

$$\tfrac{1}{2}\varepsilon_{\text{C}} = \frac{\frac{dW}{dt}}{\frac{dQ_{\text{h}}}{dt}} = \frac{\frac{dW}{dt}}{\frac{dW}{dt} + \frac{dQ_{\text{c}}}{dt}}$$

Solve for dQ_c/dt to obtain:

$$\frac{dQ_c}{dt} = \left(\frac{2}{\varepsilon_C} - 1\right)\frac{dW}{dt}$$

Assuming that the inventor has measured the work done per cycle by his invention correctly:

$$\frac{dQ_c}{dt} = \left(\frac{2}{0.201} - 1\right)(125\text{ W}) \approx 1100\text{ W}$$

a value totally inconsistent with the inventor's claims for his engine.

Ignoring his claim that 125.0 W of work are done per cycle, let's assume that his device does take in energy at the rate of 150 W each cycle and find how much work it would do with an efficiency half that of a Carnot engine:

$$\tfrac{1}{2}\varepsilon_C = \frac{\frac{dW}{dt}}{\frac{dQ_h}{dt}} \Rightarrow \frac{dW}{dt} = \tfrac{1}{2}\varepsilon_C \frac{dQ_h}{dt}$$

Substituting numerical values yields:

$$\frac{dW}{dt} = \tfrac{1}{2}(0.201)(150\text{ W}) \approx 15\text{ W}$$

Because $\frac{dQ_c}{dt} = \frac{dQ_h}{dt} - \frac{dW}{dt}$, a reasonable value for dQ_c/dt is:

$$\frac{dQ_c}{dt} = 150\text{ W} - 15\text{ W} = \boxed{135\text{ W}}$$

72 •• The cycle represented in Figure 19-12 (next to Problem 19-14) is for 1.00 mol of an ideal monatomic gas. The temperatures at points A and B are 300 and 750 K, respectively. What is the efficiency of the cyclic process ABCDA?

Picture the Problem Because the cycle represented in Figure 19-12 is a Carnot cycle, its efficiency is that of a Carnot engine operating between the temperatures of its isotherms.

The Carnot efficiency of the cycle is given by:

$$\varepsilon_C = 1 - \frac{T_c}{T_h}$$

Substitute numerical values and evaluate ε_C:

$$\varepsilon_C = 1 - \frac{300\text{ K}}{750\text{ K}} = \boxed{60.0\%}$$

73 •• **[SSM]** (*a*) Which of these two processes is more wasteful? (1) A block moving with 500 J of kinetic energy being slowed to rest by sliding (kinetic) friction when the temperature of the environment is 300 K, or (2) A reservoir at 400 K releasing 1.00 kJ of heat to a reservoir at 300 K? Explain your choice. *Hint: How much of the 1.00 kJ of heat could be converted into work by an ideal cyclic process?* (*b*) What is the change in entropy of the universe for each process?

Picture the Problem All 500 J of mechanical energy are lost, i.e., transformed into heat in process (1). For process (2), we can find the heat that would be converted to work by a Carnot engine operating between the given temperatures and subtract that amount of work from 1.00 kJ to find the energy that is lost. In Part (*b*) we can use its definition to find the change in entropy for each process.

(*a*) For process (2):

$$W_{2,\max} = W_{\text{recovered}} = \varepsilon_{\text{C}} Q_{\text{in}}$$

The efficiency of a Carnot engine operating between temperatures T_{h} and T_{c} is given by:

$$\varepsilon_{\text{C}} = 1 - \frac{T_{\text{c}}}{T_{\text{h}}}$$

and hence

$$W_{\text{recovered}} = \left(1 - \frac{T_{\text{c}}}{T_{\text{h}}}\right) Q_{\text{in}}$$

Substitute for ε_{C} to obtain:

$$W_{\text{recovered}} = \left(1 - \frac{300\text{ K}}{400\text{ K}}\right)(1.00\text{ kJ}) = 250\text{ J}$$

or

750 J are lost.

Process (1) produces more waste heat. Process (2) is more wasteful of ***available*** work.

(*b*) Find the change in entropy of the universe for process (1):

$$\Delta S_1 = \frac{\Delta Q}{T} = \frac{500\text{ J}}{300\text{ K}} = \boxed{1.67\text{ J/K}}$$

Express the change in entropy of the universe for process (2):

$$\Delta S_2 = \Delta S_{\text{h}} + \Delta S_{\text{c}} = -\frac{\Delta Q}{T_{\text{h}}} + \frac{\Delta Q}{T_{\text{c}}}$$

$$= \Delta Q\left(\frac{1}{T_{\text{c}}} - \frac{1}{T_{\text{h}}}\right)$$

Substitute numerical values and evaluate ΔS_2:

$$\Delta S_2 = (1.00\text{ kJ})\left(\frac{1}{300\text{ K}} - \frac{1}{400\text{ K}}\right)$$

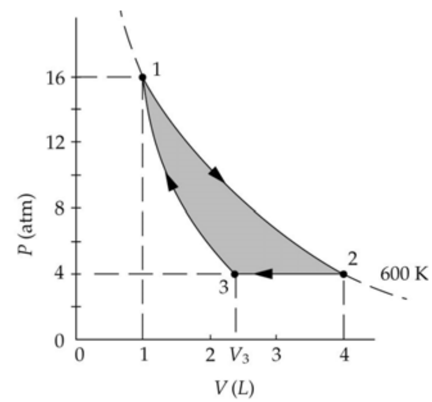
$$= \boxed{0.833\text{ J/K}}$$

74 •• Helium, a monatomic gas, is initially at a pressure of 16 atm, a volume of 1.0 L, and a temperature of 600 K. It is quasi-statically expanded at constant temperature until its volume is 4.0 L and is then quasi-statically compressed at constant pressure until its volume and temperature are such that a quasi-static adiabatic compression will return the gas to its original state. (*a*) Sketch this

cycle on a *PV* diagram. (*b*) Find the volume and temperature after the compression at constant pressure. (*c*) Find the work done during each step of the cycle. (*d*) Find the efficiency of the cycle.

Picture the Problem Denote the three states of the gas as 1, 2, and 3 with 1 being the initial state. We can use the ideal-gas law and the equation of state for an adiabatic process to find the temperatures, volumes, and pressures at points 1, 2, and 3. To find the work done during each cycle, we can use the equations for the work done during isothermal, isobaric, and adiabatic processes. Finally, we find the efficiency of the cycle from the work done each cycle and the heat that enters the system during the isothermal expansion.

(*a*) The *PV* diagram of the cycle is shown to the right.



(*b*) Apply the ideal-gas law to the isothermal expansion 1→2 to find P_2:

$$P_2 = P_1\frac{V_1}{V_2} = (16\,\text{atm})\left(\frac{1.0\,\text{L}}{4.0\,\text{L}}\right) = 4.0\,\text{atm}$$

Apply an equation for an adiabatic process to relate the pressures and volumes at 1 and 3:

$$P_1V_1^\gamma = P_3V_3^\gamma \Rightarrow V_3 = V_1\left(\frac{P_1}{P_3}\right)^{1/\gamma}$$

Substitute numerical values and evaluate V_3:

$$V_3 = (1.0\,\text{L})\left(\frac{16\,\text{atm}}{4.0\,\text{atm}}\right)^{1/1.67} = 2.294\,\text{L}$$

$$= \boxed{2.3\,\text{L}}$$

Apply an equation for an adiabatic process (γ=1.67) to relate the temperatures and volumes at 1 and 3:

$$T_3V_3^{\gamma-1} = T_1V_1^{\gamma-1} \Rightarrow T_3 = T_1\left(\frac{V_1}{V_3}\right)^{\gamma-1}$$

Substitute numerical values and evaluate T_3:

$$T_3 = (600\,\text{K})\left(\frac{1.0\,\text{L}}{2.294\,\text{L}}\right)^{1.67-1} = 344\,\text{K}$$
$$= \boxed{3.4\times10^2\ \text{K}}$$

(*c*) Express the work done each cycle:

$$W = W_{12} + W_{23} + W_{31} \qquad (1)$$

For the process 1→2:

$$W_{12} = nRT_1 \ln\left(\frac{V_2}{V_1}\right) = P_1V_1 \ln\left(\frac{V_2}{V_1}\right)$$
$$= (16\,\text{atm})(1.0\,\text{L})\ln\left(\frac{4.0\,\text{L}}{1.0\,\text{L}}\right)$$
$$= 22.18\,\text{atm}\cdot\text{L}$$

For the process 2→3:

$$W_{23} = P_2\Delta V_{23}$$
$$= (4.0\,\text{atm})(2.294\,\text{L} - 4.00\,\text{L})$$
$$= -6.824\,\text{atm}\cdot\text{L}$$

For the process 3→1:

$$W_{31} = -C_\text{V}\Delta T_{31} = -\tfrac{3}{2}nR(T_1 - T_3) = -\tfrac{3}{2}(P_1V_1 - P_3V_3)$$
$$= -\tfrac{3}{2}\left[(16\,\text{atm})(1.0\,\text{L}) - (4.0\,\text{atm})(2.294\,\text{L})\right]$$
$$= -10.24\,\text{atm}\cdot\text{L}$$

Substitute numerical values in equation (1) and evaluate W:

$$W = 22.18\,\text{atm}\cdot\text{L} - 6.824\,\text{atm}\cdot\text{L} - 10.24\,\text{atm}\cdot\text{L}$$
$$= 5.116\,\text{atm}\cdot\text{L} = \boxed{5\ \text{atm}\cdot\text{L}}$$

(*d*) Use its definition to express the efficiency of the cycle:

$$\varepsilon = \frac{W}{Q_\text{in}} = \frac{W}{Q_{12}} = \frac{W}{W_{12}}$$

Substitute numerical values and evaluate ε:

$$\varepsilon = \frac{5.116\,\text{atm}\cdot\text{L}}{22.18\,\text{atm}\cdot\text{L}} \approx \boxed{20\%}$$

75 •• **[SSM]** A heat engine that does the work of blowing up a balloon at a pressure of 1.00 atm absorbs 4.00 kJ from a reservoir at 120ºC. The volume of the balloon increases by 4.00 L, and heat is released to a reservoir at a temperature T_c, where $T_\text{c} < 120$ºC. If the efficiency of the heat engine is 50% of the efficiency of a Carnot engine working between the same two reservoirs, find the temperature T_c.

Picture the Problem We can express the temperature of the cold reservoir as a function of the Carnot efficiency of an ideal engine and, given that the efficiency of the heat engine is half that of a Carnot engine, relate T_c to the work done by and the heat input to the real heat engine.

Using its definition, relate the efficiency of a Carnot engine working between the same reservoirs to the temperature of the cold reservoir:

$$\varepsilon_C = 1 - \frac{T_c}{T_h} \Rightarrow T_c = T_h\left(1 - \varepsilon_C\right)$$

Relate the efficiency of the heat engine to that of a Carnot engine working between the same temperatures:

$$\varepsilon = \frac{W}{Q_{in}} = \tfrac{1}{2}\varepsilon_C \Rightarrow \varepsilon_C = \frac{2W}{Q_{in}}$$

Substitute for ε_C to obtain:

$$T_c = T_h\left(1 - \frac{2W}{Q_{in}}\right)$$

The work done by the gas in expanding the balloon is:

$$W = P\Delta V = (1.00\,\text{atm})(4.00\,\text{L})$$
$$= 4.00\,\text{atm}\cdot\text{L}$$

Substitute numerical values and evaluate T_c:

$$T_c = (393\,\text{K})\left(1 - \frac{2\left(4.00\,\text{atm}\cdot\text{L}\times\dfrac{101.325\,\text{J}}{\text{atm}\cdot\text{L}}\right)}{4.00\,\text{kJ}}\right) = \boxed{313\,\text{K}}$$

76 •• Show that the coefficient of performance of a Carnot engine run as a refrigerator is related to the efficiency of a Carnot engine operating between the same two temperatures by $\varepsilon_C \times \text{COP}_C = T_c/T_h$.

Picture the Problem We can use the definitions of the COP and ε_C to show that their relationship is $\varepsilon_C \times \text{COP}_C = T_C/T_h$.

Using the definition of the COP, relate the heat removed from the cold reservoir to the work done each cycle:

$$\text{COP} = \frac{Q_c}{W}$$

Apply energy conservation to relate Q_c, Q_h, and W:

$$Q_c = Q_h - W$$

Substitute for Q_c to obtain:

$$\text{COP} = \frac{Q_h - W}{W}$$

Divide the numerator and denominator by Q_h and simplify to obtain:

$$\text{COP} = \frac{Q_h - W}{W} = \frac{1 - \dfrac{W}{Q_h}}{\dfrac{W}{Q_h}}$$

Because $\varepsilon_C = \dfrac{W}{Q_h} = 1 - \dfrac{T_c}{T_h}$:

$$\text{COP}_c = \frac{1 - \varepsilon_C}{\varepsilon_C} = \frac{1 - \left(1 - \dfrac{T_c}{T_h}\right)}{\varepsilon_C} = \frac{\dfrac{T_c}{T_h}}{\varepsilon_C}$$

and

$$\boxed{\varepsilon_C \times \text{COP}_c = \frac{T_c}{T_h}}$$

77 •• A freezer has a temperature $T_c = -23$ºC. The air in the kitchen has a temperature $T_h = 27$ºC. The freezer is not perfectly insulated and some heat leaks through the walls of the freezer at a rate of 50 W. Find the power of the motor that is needed to maintain the temperature in the freezer.

Picture the Problem We can use the definition of the COP to express the work the motor must do to maintain the temperature of the freezer in terms of the rate at which heat flows into the freezer. Differentiation of this expression with respect to time will yield an expression for the power of the motor that is needed to maintain the temperature in the freezer.

Using the definition of the COP, relate the heat that must be removed from the freezer to the work done by the motor:

$$\text{COP} = \frac{Q_c}{W} \Rightarrow W = \frac{Q_c}{\text{COP}}$$

Differentiate this expression with respect to time to express the power of the motor:

$$P = \frac{dW}{dt} = \frac{dQ_c/dt}{\text{COP}}$$

Express the maximum COP of the motor:

$$\text{COP}_{\max} = \frac{T_c}{\Delta T}$$

Substitute for COP_{max} to obtain:

$$P=\frac{dQ_{\text{c}}}{dt}\frac{\Delta T}{T_{\text{c}}}$$

Substitute numerical values and evaluate P:

$$P=(50\,\text{W})\left(\frac{50\,\text{K}}{250\,\text{K}}\right)=\boxed{10\,\text{W}}$$

78 •• In a heat engine, 2.00 mol of a diatomic gas are taken through the cycle ABCA as shown in Figure 19-20. (The *PV* diagram is not drawn to scale.) At A the pressure and temperature are 5.00 atm and 600 K. The volume at B is twice the volume at A. The segment BC is an adiabatic expansion and the segment CA is an isothermal compression. (*a*) What is the volume of the gas at A? (*b*) What are the volume and temperature of the gas at B? (*c*) What is the temperature of the gas at C? (*d*) What is the volume of the gas at C? (*e*) How much work is done by the gas in each of the three segments of the cycle? (*f*) How much heat is absorbed or released by the gas in each segment of this cycle?

Picture the Problem We can use the ideal-gas law to find the unknown temperatures, pressures, and volumes at points A, B, and C and then find the work done by the gas and the efficiency of the cycle by using the expressions for the work done on or by the gas and the heat that enters the system for the constant-pressure, adiabatic, and isothermal processes of the cycle.

(*a*) Apply the ideal-gas law to find the volume of the gas at A:

$$V_{\text{A}}=\frac{nRT_{\text{A}}}{P_{\text{A}}}$$

$$=\frac{(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K})}{5.00\,\text{atm}\times\frac{101.325\,\text{kPa}}{\text{atm}}}$$

$$=1.969\times10^{-2}\ \text{m}^3\times\frac{1\,\text{L}}{10^{-3}\ \text{m}^3}=19.69\,\text{L}$$

$$=\boxed{19.7\,\text{L}}$$

(*b*) We're given that $V_{\text{B}}=2V_{\text{A}}$. Hence:

$$V_{\text{B}}=2(19.69\,\text{L})=39.38\,\text{L}=\boxed{39.4\,\text{L}}$$

Apply the ideal-gas law to this constant-pressure process to obtain:

$$T_{\text{B}}=T_{\text{A}}\frac{V_{\text{B}}}{V_{\text{A}}}=(600\,\text{K})\frac{2V_{\text{A}}}{V_{\text{A}}}$$

$$=\boxed{1200\,\text{K}}$$

(*c*) Because the process C→A is isothermal:

$$T_C = T_A = \boxed{600\,\text{K}}$$

(*d*) Apply an equation for an adiabatic process (γ= 1.4) to find the volume of the gas at C:

$$T_B V_B^{\gamma-1} = T_C V_C^{\gamma-1} \Rightarrow V_C = V_B \left(\frac{T_B}{T_C}\right)^{\frac{1}{\gamma-1}}$$

Substitute numerical values and evaluate V_C:

$$V_C = (39.38\,\text{L})\left(\frac{1200\,\text{K}}{600\,\text{K}}\right)^{\frac{1}{1.4-1}} = 222.77\,\text{L}$$
$$= \boxed{223\,\text{L}}$$

(*e*) The work done by the gas during the constant-pressure process AB is given by:

$$W_{AB} = P_A(V_B - V_A) = P_A(2V_A - V_A)$$
$$= P_A V_A$$

Substitute numerical values and evaluate W_{AB}:

$$W_{AB} = (5.00\,\text{atm})(19.69\,\text{L})$$
$$= 98.45\,\text{atm}\cdot\text{L} \times \frac{101.325\,\text{J}}{\text{atm}\cdot\text{L}}$$
$$= 9.9754 \times 10^3\ \text{J} = \boxed{9.98\,\text{kJ}}$$

Apply the first law of thermodynamics to express the work done on the gas during the adiabatic expansion BC:

$$W_{BC} = \Delta E_{\text{int,BC}} - Q_{\text{in, BC}} = \Delta E_{\text{int, BC}} - 0$$
$$= \Delta E_{\text{int, BC}} = -nc_V \Delta T_{BC}$$
$$= -\tfrac{5}{2} nR\Delta T_{BC}$$

Substitute numerical values and evaluate W_{BC}:

$$W_{BC} = -\tfrac{5}{2}(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K} - 1200\,\text{K}) = 2.494 \times 10^4\ \text{J}$$
$$= \boxed{24.9\,\text{kJ}}$$

The work done by the gas during the isothermal compression CA is:

$$W_{CA} = nRT_C \ln\left(\frac{V_A}{V_C}\right) = (2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K})\ln\left(\frac{19.69\,\text{L}}{222.77\,\text{L}}\right)$$
$$= -24.20\,\text{kJ} = \boxed{-24.2\,\text{kJ}}$$

(*f*) The heat absorbed during the constant-pressure expansion AB is:

$$Q_{\mathrm{AB}} = nc_{\mathrm{P}}\Delta T_{\mathrm{A-B}} = \tfrac{7}{2}nR\Delta T_{\mathrm{A-B}} = \tfrac{7}{2}(2.00\,\mathrm{mol})\left(8.314\frac{\mathrm{J}}{\mathrm{mol\cdot K}}\right)(1200\,\mathrm{K}-600\,\mathrm{K})$$
$$= 34.92\,\mathrm{kJ} = \boxed{34.9\,\mathrm{kJ}}$$

The heat absorbed during the adiabatic expansion BC is:

$$Q_{\mathrm{BC}} = \boxed{0}$$

Use the first law of thermodynamics to find the heat absorbed during the isothermal compression CA:

$$Q_{\mathrm{CA}} = W_{\mathrm{CA}} + \Delta E_{\mathrm{int,\,CA}} = W_{\mathrm{CA}}$$
$$= \boxed{-24.2\,\mathrm{kJ}}$$

because $\Delta E_{\mathrm{int,\,CA}} = 0$ for an isothermal process.

79 •• [SSM] In a heat engine, 2.00 mol of a diatomic gas are carried through the cycle ABCDA shown in Figure 19-21. (The *PV* diagram is not drawn to scale.) The segment AB represents an isothermal expansion, the segment BC an adiabatic expansion. The pressure and temperature at A are 5.00 atm and 600 K. The volume at B is twice the volume at A. The pressure at D is 1.00 atm. (*a*) What is the pressure at B? (*b*) What is the temperature at C? (*c*) Find the total work done by the gas in one cycle.

Picture the Problem We can use the ideal-gas law to find the unknown temperatures, pressures, and volumes at points B, C, and D. We can then find the work done by the gas and the efficiency of the cycle by using the expressions for the work done on or by the gas and the heat that enters the system for the various thermodynamic processes of the cycle.

(*a*) Apply the ideal-gas law for a fixed amount of gas to the isothermal process AB to find the pressure at B:

$$P_{\mathrm{B}} = P_{\mathrm{A}}\frac{V_{\mathrm{A}}}{V_{\mathrm{B}}} = (5.00\,\mathrm{atm})\frac{V_{\mathrm{A}}}{2V_{\mathrm{A}}}$$
$$= 2.50\,\mathrm{atm}\times\frac{101.325\,\mathrm{kPa}}{1\,\mathrm{atm}} = 253.3\,\mathrm{kPa}$$
$$= \boxed{253\,\mathrm{kPa}}$$

(*b*) Apply the ideal-gas law for a fixed amount of gas to the adiabatic process BC to express the temperature at C:

$$T_{\mathrm{C}} = T_{\mathrm{B}}\frac{P_{\mathrm{C}}V_{\mathrm{C}}}{P_{\mathrm{B}}V_{\mathrm{B}}} \qquad (1)$$

Use the ideal-gas law to find the volume of the gas at B:

$$V_B = \frac{nRT_B}{P_B} = \frac{(2.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K})}{253.3\,\text{kPa}} = 39.39\,\text{L}$$

Use the equation of state for an adiabatic process and $\gamma = 1.4$ to find the volume occupied by the gas at C:

$$V_C = V_B\left(\frac{P_B}{P_C}\right)^{1/\gamma} = (39.39\,\text{L})\left(\frac{2.50\,\text{atm}}{1.00\,\text{atm}}\right)^{1/1.4} = 75.78\,\text{L}$$

Substitute numerical values in equation (1) and evaluate T_C:

$$T_C = (600\,\text{K})\frac{(1.00\,\text{atm})(75.78\,\text{L})}{(2.50\,\text{atm})(39.39\,\text{L})} = \boxed{462\,\text{K}}$$

(*c*) The work done by the gas in one cycle is given by:

$$W = W_{AB} + W_{BC} + W_{CD} + W_{DA}$$

The work done during the isothermal expansion AB is:

$$W_{AB} = nRT_A \ln\left(\frac{V_B}{V_A}\right) = (2.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K})\ln\left(\frac{2\text{V}_A}{\text{V}_A}\right) = 6.915\,\text{kJ}$$

The work done during the adiabatic expansion BC is:

$$W_{BC} = -C_V\Delta T_{BC} = -\tfrac{5}{2}nR\Delta T_{BC} = -\tfrac{5}{2}(2.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(462\,\text{K} - 600\,\text{K}) = 5.737\,\text{kJ}$$

The work done during the isobaric compression CD is:

$$W_{CD} = P_C(V_D - V_C) = (1.00\,\text{atm})(19.7\,\text{L} - 75.78\,\text{L}) = -56.09\,\text{atm}\cdot\text{L}\times\frac{101.325\,\text{J}}{\text{atm}\cdot\text{L}} = -5.680\,\text{kJ}$$

Express and evaluate the work done during the constant-volume process DA:

$$W_{DA} = 0$$

Substitute numerical values and evaluate W:

$$W = 6.915\,\text{kJ} + 5.737\,\text{kJ} - 5.680\,\text{kJ} + 0$$
$$= 6.972\,\text{kJ} = \boxed{6.97\,\text{kJ}}$$

80 •• In a heat engine, 2.00 mol of a monatomic gas are taken through the cycle ABCA as shown in Figure 19-20. (The *PV* diagram is not drawn to scale.) At A the pressure and temperature are 5.00 atm and 600 K. The volume at B is twice the volume at A. The segment BC is an adiabatic expansion and the segment CA is an isothermal compression. (*a*) What is the volume of the gas at A? (*b*) What are the volume and temperature of the gas at B? (*c*) What is the temperature of the gas at C? (*d*) What is the volume of the gas at C? (*e*) How much work is done by the gas in each of the three segments of the cycle? (*f*) How much heat is absorbed by the gas in each segment of the cycle?

Picture the Problem We can use the ideal-gas law to find the unknown temperatures, pressures, and volumes at points A, B, and C and then find the work done by the gas and the efficiency of the cycle by using the expressions for the work done on or by the gas and the heat that enters the system for the isobaric, adiabatic, and isothermal processes of the cycle.

(*a*) Apply the ideal-gas law to find the volume of the gas at A:

$$V_{\text{A}} = \frac{nRT_{\text{A}}}{P_{\text{A}}}$$
$$= \frac{(2.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K})}{5.00\,\text{atm}\times\frac{101.325\,\text{kPa}}{\text{atm}}}$$
$$= 19.69\,\text{L} = \boxed{19.7\,\text{L}}$$

(*b*) We're given that:

$$V_{\text{B}} = 2V_{\text{A}} = 2(19.69\,\text{L}) = 39.39\,\text{L}$$
$$= \boxed{39.4\,\text{L}}$$

Apply the ideal-gas law to this isobaric process to find the temperature at B:

$$T_{\text{B}} = T_{\text{A}}\frac{V_{\text{B}}}{V_{\text{A}}} = (600\,\text{K})\frac{2V_{\text{A}}}{V_{\text{A}}}$$
$$= \boxed{1200\,\text{K}}$$

(*c*) Because the process CA is isothermal:

$$T_{\text{C}} = T_{\text{A}} = \boxed{600\,\text{K}}$$

(*d*) Apply an equation for an adiabatic process ($\gamma = 5/3$) to express the volume of the gas at C:

$$T_{\text{B}}V_{\text{B}}^{\gamma-1} = T_{\text{C}}V_{\text{C}}^{\gamma-1} \Rightarrow V_{\text{C}} = V_{\text{B}}\left(\frac{T_{\text{B}}}{T_{\text{C}}}\right)^{\frac{1}{\gamma-1}}$$

Substitute numerical values and evaluate V_C:

$$V_C = (39.39\,\text{L})\left(\frac{1200\,\text{K}}{600\,\text{K}}\right)^{\frac{3}{2}} = 111.4\,\text{L} = \boxed{111\,\text{L}}$$

(*e*) The work done by the gas during the isobaric process AB is given by:

$$W_{AB} = P_A(V_B - V_A) = P_A(2V_A - V_A) = P_A V_A$$

Substitute numerical values and evaluate W_{AB}:

$$W_{AB} = (5.00\,\text{atm})(19.69\,\text{L}) = 98.45\,\text{atm}\cdot\text{L}\times\frac{101.325\,\text{J}}{\text{atm}\cdot\text{L}} = 9.975\,\text{kJ} = \boxed{9.98\,\text{kJ}}$$

Apply the first law of thermodynamics to express the work done by the gas during the adiabatic expansion BC:

$$W_{BC} = \Delta E_{\text{int, BC}} - Q_{\text{in, BC}} = \Delta E_{\text{int, BC}} - 0 = \Delta E_{\text{int, BC}} = -(nc_V\Delta T_{BC}) = -\tfrac{3}{2}nR\Delta T_{BC}$$

Substitute numerical values and evaluate W_{BC}:

$$W_{BC} = -\tfrac{3}{2}(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K} - 1200\,\text{K}) = 14.97\,\text{kJ} = \boxed{15.0\,\text{kJ}}$$

The work done by the gas during the isothermal compression CA is:

$$W_{CA} = nRT_C\ln\left(\frac{V_A}{V_C}\right) = (2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K})\ln\left(\frac{19.69\,\text{L}}{111.4\,\text{L}}\right) = -17.29\,\text{kJ}\ \boxed{-17.3\,\text{kJ}}$$

(*f*) The heat absorbed during the isobaric expansion AB is:

$$Q_{\text{in, AB}} = nc_P\Delta T_{AB} = \tfrac{5}{2}nR\Delta T_{AB} = \tfrac{5}{2}(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(1200\,\text{K} - 600\,\text{K}) = \boxed{24.9\,\text{kJ}}$$

Express and evaluate the heat absorbed during the adiabatic expansion BC:

$$Q_{BC} = \boxed{0}$$

Use the first law of thermodynamics to express and evaluate the heat absorbed during the isothermal compression CA:

$$Q_{CA} = W_{CA} + \Delta E_{int,\,CA} = W_{CA}$$
$$= \boxed{-17.3\,\text{kJ}}$$

because $\Delta E_{int} = 0$ for an isothermal process.

81 •• In a heat engine, 2.00 mol of a monatomic gas are carried through the cycle ABCDA shown in Figure 19-21. (The *PV* diagram is not drawn to scale.) The segment AB represents an isothermal expansion, the segment BC an adiabatic expansion. The pressure and temperature at A are 5.00 atm and 600 K. The volume at B is twice the volume at A. The pressure at D is 1.00 atm. (*a*) What is the pressure at B? (*b*) What is the temperature at C? (*c*) Find the total work done by the gas in one cycle.

Picture the Problem We can use the ideal-gas law to find the unknown temperatures, pressures, and volumes at points B, C, and D and then find the work done by the gas and the efficiency of the cycle by using the expressions for the work done on or by the gas and the heat that enters the system for the various thermodynamic processes of the cycle.

(*a*) Apply the ideal-gas law for a fixed amount of gas to the isothermal process AB:

$$P_B = P_A \frac{V_A}{V_B} = (5.00\,\text{atm})\frac{V_A}{2V_A}$$
$$= 2.50\,\text{atm} \times \frac{101.325\,\text{kPa}}{1\,\text{atm}}$$
$$= 253.3\,\text{kPa} = \boxed{253\,\text{kPa}}$$

(*b*) Apply the ideal-gas law for a fixed amount of gas to the adiabatic process BC:

$$T_C = T_B \frac{P_C V_C}{P_B V_B} \qquad (1)$$

Use the ideal-gas law to find the volume at B:

$$V_B = \frac{nRT_B}{P_B}$$
$$= \frac{(2.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K})}{253.3\,\text{kPa}}$$
$$= 39.39\,\text{L}$$

Use the equation of state for an adiabatic process and $\gamma = 5/3$ to find the volume occupied by the gas at C:

$$V_C = V_B\left(\frac{P_B}{P_C}\right)^{1/\gamma} = (39.39\,\text{L})\left(\frac{2.50\,\text{atm}}{1.00\,\text{atm}}\right)^{3/5}$$
$$= 68.26\,\text{L}$$

Substitute numerical values in equation (1) and evaluate T_C:

$$T_C = (600\,\text{K})\frac{(1.00\,\text{atm})(68.26\,\text{L})}{(2.50\,\text{atm})(39.39\,\text{L})}$$
$$= 415.9\,\text{K} = \boxed{416\,\text{K}}$$

(*c*) The work done by the gas in one cycle is given by:

$$W = W_{AB} + W_{BC} + W_{CD} + W_{DA} \quad (2)$$

The work done during the isothermal expansion AB is:

$$W_{AB} = nRT_A \ln\left(\frac{V_B}{V_A}\right) = (2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(600\,\text{K})\ln\left(\frac{2V_A}{V_A}\right) = 6.915\,\text{kJ}$$

The work done during the adiabatic expansion BC is:

$$W_{BC} = -C_V\Delta T_{BC} = -\tfrac{3}{2}nR\Delta T_{BC}$$
$$= -\tfrac{3}{2}(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(415.9\,\text{K} - 600\,\text{K})$$
$$= 4.592\,\text{kJ}$$

The work done during the isobaric compression CD is:

$$W_{CD} = P_C(V_D - V_C) = (1.00\,\text{atm})(19.7\,\text{L} - 68.26\,\text{L}) = -48.56\,\text{atm}\cdot\text{L} \times \frac{101.325\,\text{J}}{\text{atm}\cdot\text{L}}$$
$$= -4.920\,\text{kJ}$$

The work done during the constant-volume process DA is:

$$W_{DA} = 0$$

Substitute numerical values in equation (2) to obtain:

$$W = 6.915\,\text{kJ} + 4.592\,\text{kJ} - 4.920\,\text{kJ} + 0$$
$$= \boxed{6.59\,\text{kJ}}$$

82 •• Compare the efficiency of the Otto cycle to the efficiency of the Carnot cycle operating between the same maximum and minimum temperatures. (The Otto cycle is discussed in Section 19-1.)

Picture the Problem We can express the efficiency of the Otto cycle using the result from Example 19-2. We can apply the relation $TV^{\gamma-1} = \text{constant}$ to the adiabatic processes of the Otto cycle to relate the end-point temperatures to the volumes occupied by the gas at these points and eliminate the temperatures at *c* and *d*. We can use the ideal-gas law to find the highest temperature of the gas during its cycle and use this temperature to express the efficiency of a Carnot engine. Finally, we can compare the efficiencies by examining their ratio.

The efficiency of the Otto engine is given in Example 19-2:

$$\varepsilon_{\text{Otto}} = 1 - \frac{T_d - T_a}{T_c - T_b} \qquad (1)$$

where the subscripts refer to the various points of the cycle as shown in Figure 19-3.

Apply the relation $TV^{\gamma-1}$ = constant to the adiabatic process $a \to b$ to obtain:

$$T_b = T_a\left(\frac{V_a}{V_b}\right)^{\gamma-1}$$

Apply the relation $TV^{\gamma-1}$ = constant to the adiabatic process $c \to d$ to obtain:

$$T_c = T_d\left(\frac{V_d}{V_c}\right)^{\gamma-1}$$

Subtract the first of these equations from the second to obtain:

$$T_c - T_b = T_d\left(\frac{V_d}{V_c}\right)^{\gamma-1} - T_a\left(\frac{V_a}{V_b}\right)^{\gamma-1}$$

In the Otto cycle, $V_a = V_d$ and $V_c = V_b$. Substitute to obtain:

$$T_c - T_b = T_d\left(\frac{V_a}{V_b}\right)^{\gamma-1} - T_a\left(\frac{V_a}{V_b}\right)^{\gamma-1} = (T_d - T_a)\left(\frac{V_a}{V_b}\right)^{\gamma-1}$$

Substitute in equation (1) and simplify to obtain:

$$\varepsilon_{\text{Otto}} = 1 - \frac{T_d - T_a}{(T_d - T_a)\left(\frac{V_a}{V_b}\right)^{\gamma-1}} = 1 - \left(\frac{V_b}{V_a}\right)^{\gamma-1} = 1 - \frac{T_a}{T_b}$$

Note that, while T_a is the lowest temperature of the cycle, T_b is not the highest temperature.

Apply the ideal-gas law to c and b to obtain an expression for the cycle's highest temperature T_c:

$$\frac{P_c}{T_c}=\frac{P_b}{T_b}\Rightarrow T_c=T_b\frac{P_c}{P_b}>T_b$$

The efficiency of a Carnot engine operating between the maximum and minimum temperatures of the Otto cycle is given by:

$$\varepsilon_{\text{Carnot}}=1-\frac{T_a}{T_c}$$

Express the ratio of the efficiency of a Carnot engine to the efficiency of an Otto engine operating between the same temperatures:

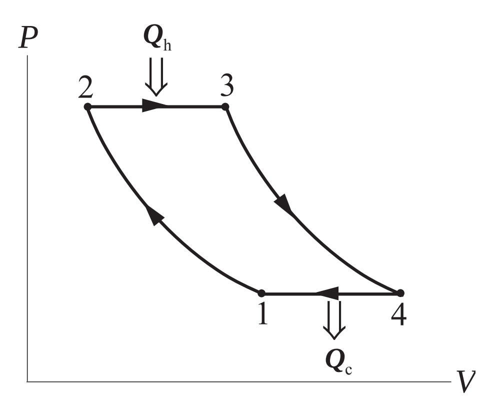
$$\frac{\varepsilon_{\text{Carnot}}}{\varepsilon_{\text{Otto}}}=\frac{1-\dfrac{T_a}{T_c}}{1-\dfrac{T_a}{T_b}}>1 \text{ because } T_c>T_b.$$

Hence, $\boxed{\varepsilon_{\text{Carnot}}>\varepsilon_{\text{Otto}}}$

83 ••• [SSM] A common practical cycle, often used in refrigeration, is the *Brayton cycle*, which involves (1) an adiabatic compression, (2) an isobaric (constant pressure) expansion,(3) an adiabatic expansion, and (4) an isobaric compression back to the original state. Assume the system begins the adiabatic compression at temperature T_1, and transitions to temperatures T_2, T_3 and T_4 after each leg of the cycle. (*a*) Sketch this cycle on a *PV* diagram. (*b*) Show that the efficiency of the overall cycle is given by $\varepsilon=1-\frac{(T_4-T_1)}{(T_3-T_2)}$. (*c*) Show that this efficiency, can be written as $\varepsilon=1-r^{(1-\gamma)/\gamma}$, where r is the pressure ratio $P_{\text{high}}/P_{\text{low}}$ of the maximum and minimum pressures in the cycle.

Picture the Problem The efficiency of the cycle is the ratio of the work done to the heat that flows into the engine. Because the adiabatic transitions in the cycle do not have heat flow associated with them, all we must do is consider the heat flow in and out of the engine during the isobaric transitions.

(*a*) The *Brayton heat engine cycle* is shown to the right. The paths 1→2 and 3→4 are adiabatic. Heat Q_h enters the gas during the isobaric transition from state 2 to state 3 and heat Q_c leaves the gas during the isobaric transition from state 4 to state 1.



(*b*) The efficiency of a heat engine is given by:

$$\varepsilon=\frac{W}{Q_{\text{in}}}=\frac{Q_{\text{h}}-Q_{\text{c}}}{Q_{\text{in}}} \qquad (1)$$

During the constant-pressure expansion from state 1 to state 2 heat enters the system:

$$Q_{23}=Q_{\text{h}}=nC_{\text{P}}\Delta T=nC_{\text{P}}\left(T_3-T_2\right)$$

During the constant-pressure compression from state 3 to state 4 heat enters the system:

$$Q_{41}=-Q_{\text{c}}=-nC_{\text{P}}\Delta T=-nC_{\text{P}}\left(T_1-T_4\right)$$

Substituting in equation (1) and simplifying yields:

$$\begin{aligned}\varepsilon&=\frac{nC_{\text{P}}\left(T_3-T_2\right)-\left(-nC_{\text{P}}\left(T_1-T_4\right)\right)}{nC_{\text{P}}\left(T_3-T_2\right)}\\&=\frac{\left(T_3-T_2\right)+\left(T_1-T_4\right)}{\left(T_3-T_2\right)}\\&=\boxed{1-\frac{\left(T_4-T_1\right)}{\left(T_3-T_2\right)}}\end{aligned}$$

(*c*) Given that, for an adiabatic transition, $TV^{\gamma-1}=\text{constant}$, use the ideal-gas law to eliminate V and obtain:

$$\frac{T^{\gamma}}{P^{\gamma-1}}=\text{constant}$$

Let the pressure for the transition from state 1 to state 2 be P_{low} and the pressure for the transition from state 3 to state 4 be P_{high}. Then for the adiabatic transition from state 1 to state 2:

$$\frac{T_1^{\gamma}}{P_{\text{low}}^{\gamma-1}}=\frac{T_2^{\gamma}}{P_{\text{high}}^{\gamma-1}}\Rightarrow T_1=\left(\frac{P_{\text{low}}}{P_{\text{high}}}\right)^{\frac{\gamma-1}{\gamma}}T_2$$

Similarly, for the adiabatic transition from state 3 to state 4:

$$T_4=\left(\frac{P_{\text{low}}}{P_{\text{high}}}\right)^{\frac{\gamma-1}{\gamma}}T_3$$

Subtract T_1 from T_4 and simplify to obtain:

$$\begin{aligned}T_4-T_1&=\left(\frac{P_{\text{low}}}{P_{\text{high}}}\right)^{\frac{\gamma-1}{\gamma}}T_3-\left(\frac{P_{\text{low}}}{P_{\text{high}}}\right)^{\frac{\gamma-1}{\gamma}}T_2\\&=\left(\frac{P_{\text{low}}}{P_{\text{high}}}\right)^{\frac{\gamma-1}{\gamma}}\left(T_3-T_2\right)\end{aligned}$$

Dividing both sides of the equation by $T_3 - T_2$ yields:

$$\frac{T_4 - T_1}{T_3 - T_2} = \left(\frac{P_{\text{low}}}{P_{\text{high}}}\right)^{\frac{\gamma-1}{\gamma}}$$

Substitute in the result of Part (*b*) and simplify to obtain:

$$\varepsilon = 1 - \left(\frac{P_{\text{low}}}{P_{\text{high}}}\right)^{\frac{\gamma-1}{\gamma}} = 1 - \left(\frac{P_{\text{high}}}{P_{\text{low}}}\right)^{\frac{1-\gamma}{\gamma}}$$

$$= \boxed{1 - (r)^{\frac{1-\gamma}{\gamma}}}$$

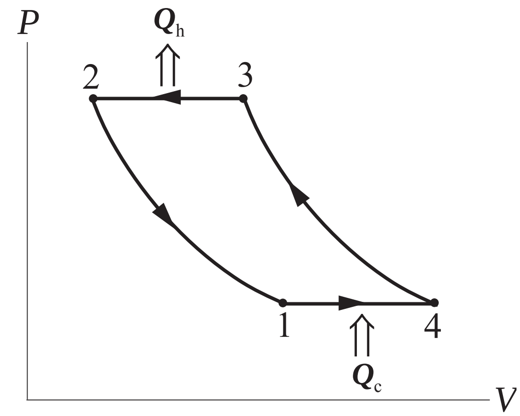
where $r = \dfrac{P_{\text{high}}}{P_{\text{low}}}$

84 ••• Suppose the Brayton cycle engine (see Problem 83) is run in reverse as a refrigerator in your kitchen. In this case, the cycle begins at temperature T_1 and expands at constant pressure until its temperature T_4. Then the gas is adiabatically compressed, until its temperature is T_3. And then it is compressed at constant pressure until its temperature T_2. Finally, it adiabatically expands until it returns to its initial state at temperature T_1. (*a*) Sketch this cycle on a *PV* diagram. (*b*) Show that the coefficient of performance is $\text{COP}_\text{B} = \dfrac{(T_4 - T_1)}{(T_3 - T_2 - T_4 + T_1)}$.

(*c*) Suppose your "Brayton cycle refrigerator" is run as follows. The cylinder containing the refrigerant (a monatomic gas) has an initial volume and pressure of 60 mL and 1.0 atm. After the expansion at constant pressure, the volume and temperature are 75 mL and –25°C. The pressure ratio $r = P_{\text{high}}/P_{\text{low}}$ for the cycle is 5.0. What is the coefficient of performance for your refrigerator? (*d*) To absorb heat from the food compartment at the rate of 120 W, what is the rate at which electrical energy must be supplied to the motor of this refrigerator? (*e*) Assuming the refrigerator motor is actually running for only 4.0 h each day, how much does it add to your monthly electric bill. Assume 15 cents per kWh of electric energy and thirty days in a month.

Picture the Problem The efficiency of the Brayton refrigerator cycle is the ratio of the heat that enters the system to the work done to operate the refrigerator. Because the adiabatic transitions in the cycle do not have heat flow associated with them, all we must do is consider the heat flow in and out of the refrigerator during the isobaric transitions.

(*a*) The *Brayton refrigerator cycle* is shown to the right. The paths 1→2 and 3→4 are adiabatic. Heat Q_c enters the gas during the constant-pressure transition from state 1 to state 4 and heat Q_h leaves the gas during the constant-pressure transition from state 3 to state 2.



(*b*) The coefficient of performance of the Brayton cycle refrigerator is given by:

$$\mathrm{COP_B} = \frac{Q_c}{W} \qquad (1)$$

where $W = Q_{32} - Q_{14}$

During the constant-pressure compression from state 3 to state 2 heat leaves the system:

$$Q_{32} = -Q_h = -nC_P\Delta T = -nC_P(T_2 - T_3)$$

During the constant-pressure expansion from state 1 to state 4 heat enters the system:

$$Q_{14} = Q_c = nC_P\Delta T = nC_P(T_4 - T_1)$$

Substituting in equation (1) and simplifying yields:

$$\begin{aligned}\mathrm{COP_B} &= \frac{nC_P(T_4 - T_1)}{-nC_P(T_2 - T_3) - nC_P(T_4 - T_1)} \\ &= \frac{(T_4 - T_1)}{-(T_4 - T_1) - (T_2 - T_3)} \\ &= \boxed{\frac{T_4 - T_1}{T_3 - T_2 - T_4 + T_1}}\end{aligned}$$

(*c*) The $\mathrm{COP_B}$ requires the temperatures corresponding to states 1, 2, 3, and 4. We're given that the temperature in state 4 is:

$$T_4 = -25°\mathrm{C} + 273\ \mathrm{K} = 248\ \mathrm{K}$$

For the constant-pressure transition from state 1 to state 4, the quotient T/V is constant:

$$\frac{T_1}{V_1} = \frac{T_4}{V_4} \Rightarrow T_1 = \left(\frac{V_1}{V_4}\right)T_4$$

Substitute numerical values and evaluate T_1:

$$T_1 = \left(\frac{60\ \mathrm{mL}}{75\ \mathrm{mL}}\right)(248\ \mathrm{K}) = 198\ \mathrm{K}$$

Given that, for an adiabatic transition, $TV^{\gamma-1} = \text{constant}$, use the ideal-gas law to eliminate V and obtain:

$$\frac{T^{\gamma}}{P^{\gamma-1}} = \text{constant}$$

For the adiabatic transition from state 4 to state 3:

$$\frac{T_3^{\gamma}}{P_3^{\gamma-1}} = \frac{T_4^{\gamma}}{P_4^{\gamma-1}} \Rightarrow T_3 = \left(\frac{P_3}{P_4}\right)^{\frac{\gamma-1}{\gamma}} T_4$$

Substitute numerical values and evaluate T_3:

$$T_3 = (5)^{\frac{1.67-1}{1.67}}(248\text{ K}) = 473\text{ K}$$

Similarly, for the adiabatic transition from state 2 to state 1:

$$T_2 = \left(\frac{P_2}{P_1}\right)^{\frac{\gamma-1}{\gamma}} T_1 = (5)^{\frac{1.67-1}{1.67}}(198\text{ K})$$
$$= 378\text{ K}$$

Substitute numerical values in the expression derived in Part (a) and evaluate COP_B:

$$\text{COP}_\text{B} = \frac{248\text{ K} - 198\text{ K}}{473\text{ K} - 378\text{ K} - 248\text{ K} + 198\text{ K}}$$
$$= \boxed{1.1}$$

(d) From the definition of COP_B:

$$W = \frac{Q_c}{\text{COP}_\text{B}}$$

The rate at which energy must be supplied to this refrigerator is given by:

$$\frac{dW}{dt} = \frac{1}{\text{COP}_\text{B}}\frac{dQ_\text{c}}{dt}$$

or, if the frequency of the AC power input is f,

$$\frac{dW}{dt} = \frac{fQ_\text{c}}{\text{COP}_\text{B}}$$

Express the heat Q_c that is drawn from the cold reservoir:

$$Q_\text{c} = nC_\text{P}\Delta T = nC_\text{P}(T_4 - T_1)$$

Substituting for Q_c yields:

$$\frac{dW}{dt} = \frac{fnC_\text{P}(T_4 - T_1)}{\text{COP}_\text{B}}$$

Use the ideal-gas law to express the number of moles of the gas:

$$n = \frac{P_4V_4}{RT_4}$$

Because the gas is monatomic, $C_P = \frac{5}{2}R$. Substitute for n and C_P to obtain:

$$\frac{dW}{dt} = \frac{\frac{5}{2} f \frac{P_4V_4}{RT_4} R(T_4 - T_1)}{\text{COP}_\text{B}} = \frac{\frac{5}{2} fP_4V_4(T_4 - T_1)}{(\text{COP}_\text{B})T_4}$$

Substitute numerical values and evaluate dW/dt:

$$\frac{dW}{dt} = \frac{\frac{5}{2}(60\ \text{s}^{-1})(101.325\ \text{kPa})\left(75\ \text{mL} \times \frac{10^{-3}\ \text{m}^3}{\text{L}}\right)(248\ \text{K} - 198\ \text{K})}{(1.11)(248\ \text{K})} = 207\ \text{W}$$
$$= \boxed{0.21\ \text{kW}}$$

(*e*) The monthly cost of operation is given by

$$\text{Monthly Cost} = \text{Cost Per Unit of Power} \times \text{Power Consumption}$$
$$= \text{rate} \times \text{daily consumption} \times \text{number of days per month}$$

Substitute numerical values and evaluate the monthly cost of operation:

$$\text{Monthly Cost} = \frac{\$0.15}{\text{kWh}} \times 0.207\ \text{kW} \times \frac{4.0\ \text{h}}{\text{d}} \times 30\ \text{d} \approx \boxed{\$4}$$

85 ••• Using $\Delta S = C_V \ln(T_2/T_1) + nR\ln(V_2/V_1)$ (Equation 19-16) for the entropy change of an ideal gas, show explicitly that the entropy change is zero for a quasi-static adiabatic expansion from state (V_1, T_1) to state (V_2, T_2).

Picture the Problem We can use $nR = C_P - C_V$, $\gamma = C_P/C_V$, and $TV^{\gamma-1}$ = a constant to show that the entropy change for a quasi-static adiabatic expansion that proceeds from state (V_1,T_1) to state (V_2,T_2) is zero.

Express the entropy change for a general process that proceeds from state 1 to state 2:

$$\Delta S = C_V \ln\left(\frac{T_2}{T_1}\right) + nR\ln\left(\frac{V_2}{V_1}\right)$$

For an adiabatic process:

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{\gamma-1}$$

Substitute for $\frac{T_2}{T_1}$ and simplify to obtain:

$$\Delta S = C_V \ln\left(\frac{V_1}{V_2}\right)^{\gamma-1} + nR\ln\left(\frac{V_2}{V_1}\right) = \ln\left(\frac{V_2}{V_1}\right)\left[nR + \frac{C_V \ln\left(\frac{V_1}{V_2}\right)^{\gamma-1}}{\ln\frac{V_2}{V_1}}\right]$$

$$= \ln\left(\frac{V_2}{V_1}\right)\left[nR + \frac{(\gamma-1)C_V \ln\left(\frac{V_1}{V_2}\right)}{-\ln\frac{V_1}{V_2}}\right] = \ln\left(\frac{V_2}{V_1}\right)\left[nR - (\gamma-1)C_V\right]$$

Use the relationship between C_P and C_V to obtain:

$$nR = C_P - C_V$$

Substituting for nR and γ and simplifying yields:

$$\Delta S = \ln\left(\frac{V_2}{V_1}\right)\left[C_P - C_V - \left(\frac{C_p}{C_V} - 1\right)C_V\right]$$
$$= \boxed{0}$$

86 ••• (a) Show that if the refrigerator statement of the second law of thermodynamics were not true, then the entropy of the universe could decrease. (b) Show that if the heat-engine statement of the second law were not true, then the entropy of the universe could decrease. (c) A third statement of the second law is that the entropy of the universe cannot decrease. Have you just proved that this statement is equivalent to the refrigerator and heat-engine statements?

Picture the Problem

(a) Suppose the refrigerator statement of the second law is violated in the sense that heat Q_c is taken from the cold reservoir and an equal amount of heat is transferred to the hot reservoir and $W = 0$. The entropy change of the universe is then $\Delta S_u = Q_c/T_h - Q_c/T_c$. Because $T_h > T_c$, $S_u < 0$, i.e., the entropy of the universe would decrease.

(b) In this case, heat Q_h is taken from the hot reservoir and no heat is rejected to the cold reservoir; that is, $Q_c = 0$, then the entropy change of the universe is $\Delta S_u = -Q_h/T_h + 0$, which is negative. Again, the entropy of the universe would decrease.

(*c*) The heat-engine and refrigerator statements of the second law only state that *some* heat must be rejected to a cold reservoir and *some* work must be done to transfer heat from the cold to the hot reservoir, but these statements do not specify the minimum amount of heat rejected or work that must be done. The statement $\Delta S_u \geq 0$ is more restrictive. The heat-engine and refrigerator statements in conjunction with the Carnot efficiency are equivalent to $\Delta S_u \geq 0$.

87 ••• Suppose that two heat engines are connected in series, such that the heat released by the first engine is used as the heat absorbed by the second engine as shown in Figure 19-22. The efficiencies of the engines are ε_1 and ε_2, respectively. Show that the net efficiency of the combination is given by $\varepsilon_{\text{net}} = \varepsilon_1 + \varepsilon_2 - \varepsilon_1\varepsilon_2$.

Picture the Problem We can express the net efficiency of the two engines in terms of W_1, W_2, and Q_h and then use $\varepsilon_1 = W_1/Q_h$ and $\varepsilon_2 = W_2/Q_m$ to eliminate W_1, W_2, Q_h, and Q_m.

Express the net efficiency of the two heat engines connected in series:

$$\varepsilon_{\text{net}} = \frac{W_1 + W_2}{Q_h}$$

Express the efficiencies of engines 1 and 2:

$$\varepsilon_1 = \frac{W_1}{Q_h} \text{ and } \varepsilon_2 = \frac{W_2}{Q_m}$$

Solve for W_1 and W_2 and substitute to obtain:

$$\varepsilon_{\text{net}} = \frac{\varepsilon_1 Q_h + \varepsilon_2 Q_m}{Q_h} = \varepsilon_1 + \frac{Q_m}{Q_h}\varepsilon_2$$

Express the efficiency of engine 1 in terms of Q_m and Q_h:

$$\varepsilon_1 = 1 - \frac{Q_m}{Q_h} \Rightarrow \frac{Q_m}{Q_h} = 1 - \varepsilon_1$$

Substitute for Q_m/Q_h and simplify to obtain:

$$\varepsilon_{\text{net}} = \varepsilon_1 + (1 - \varepsilon_1)\varepsilon_2 = \boxed{\varepsilon_1 + \varepsilon_2 - \varepsilon_1\varepsilon_2}$$

88 ••• Suppose that two heat engines are connected in series, such that the heat released by the first engine is used as the heat absorbed by the second engine, as shown in Figure 19-22. Suppose that each engine is an ideal reversible heat engine. Engine 1 operates between temperatures T_h and T_m and Engine 2 operates between T_m and T_c, where $T_h > T_m > T_c$. Show that the net efficiency of the combination is given by $\varepsilon_{\text{net}} = 1 - \frac{T_c}{T_h}$. (Note that this result means that two

reversible heat engines operating ″in series″ are equivalent to one reversible heat engine operating between the hottest and coldest reservoirs.)

Picture the Problem We can express the net efficiency of the two engines in terms of W_1, W_2, and Q_h and then use $\varepsilon_1 = W_1/Q_h$ and $\varepsilon_2 = W_2/Q_m$ to eliminate W_1, W_2, Q_h, and Q_m. Finally, we can substitute the expressions for the efficiencies of the ideal reversible engines to obtain $\varepsilon_{net} = 1 - T_c/T_h$.

Express the efficiencies of ideal reversible engines 1 and 2:

$$\varepsilon_1 = 1 - \frac{T_m}{T_h} \quad (1)$$

and

$$\varepsilon_2 = 1 - \frac{T_c}{T_m} \quad (2)$$

The net efficiency of the two engines connected in series is given by:

$$\varepsilon_{net} = \frac{W_1 + W_2}{Q_h} \quad (3)$$

Express the efficiencies of engines 1 and 2:

$$\varepsilon_1 = \frac{W_1}{Q_h} \text{ and } \varepsilon_2 = \frac{W_2}{Q_m}$$

Solve for W_1 and W_2 and substitute in equation (3) to obtain:

$$\varepsilon_{net} = \frac{\varepsilon_1 Q_h + \varepsilon_2 Q_m}{Q_h} = \varepsilon_1 + \frac{Q_m}{Q_h}\varepsilon_2$$

Express the efficiency of engine 1 in terms of Q_m and Q_h:

$$\varepsilon_1 = 1 - \frac{Q_m}{Q_h} \Rightarrow \frac{Q_m}{Q_h} = 1 - \varepsilon_1$$

Substitute for $\frac{Q_m}{Q_h}$ to obtain:

$$\varepsilon_{net} = \varepsilon_1 + (1 - \varepsilon_1)\varepsilon_2$$

Substitute for ε_1 and ε_2 and simplify to obtain:

$$\varepsilon_{net} = 1 - \frac{T_m}{T_h} + \left(\frac{T_m}{T_h}\right)\left(1 - \frac{T_c}{T_m}\right)$$

$$= 1 - \frac{T_m}{T_h} + \frac{T_m}{T_h} - \frac{T_c}{T_h} = \boxed{1 - \frac{T_c}{T_h}}$$

89 ••• [SSM] The English mathematician and philosopher Bertrand Russell (1872-1970) once said that if a million monkeys were given a million typewriters and typed away at random for a million years, they would produce all of Shakespeare’s works. Let us limit ourselves to the following fragment of Shakespeare (*Julius Caesar* III:ii):

Friends, Romans, countrymen! Lend me your ears.
I come to bury Caesar, not to praise him.
The evil that men do lives on after them,
The good is oft interred with the bones.
So let it be with Caesar.
The noble Brutus hath told you that Caesar was ambitious,
And, if so, it were a grievous fault,
And grievously hath Caesar answered it . . .

Even with this small fragment, it will take a lot longer than a million years! By what factor (roughly speaking) was Russell in error? Make any reasonable assumptions you want. (You can even assume that the monkeys are immortal.)

Picture the Problem There are 26 letters and four punctuation marks (space, comma, period, and exclamation point) used in the English language, disregarding capitalization, so we have a grand total of 30 characters to choose from. This fragment is 330 characters (including spaces) long; there are then 30^{330} different possible arrangements of the character set to form a fragment this long. We can use this number of possible arrangements to express the probability that one monkey will write out this passage and then an estimate of a monkey's typing speed to approximate the time required for one million monkeys to type the passage from Shakespeare.

Assuming the monkeys type at random, express the probability P that one monkey will write out this passage:

$$P = \frac{1}{30^{330}}$$

Use the approximation $30 \approx \sqrt{1000} = 10^{1.5}$ to obtain:

$$P = \frac{1}{10^{(1.5)(330)}} = \frac{1}{10^{495}} = 10^{-495}$$

Assuming the monkeys can type at a rate of 1 character per second, it would take about 330 s to write a passage of length equal to the quotation from Shakespeare. Find the time T required for a million monkeys to type this particular passage by accident:

$$T = \frac{(330\,\text{s})(10^{495})}{10^6} = (3.30\times10^{491}\,\text{s})\left(\frac{1\,\text{y}}{3.16\times10^{7}\,\text{s}}\right) \approx \boxed{10^{484}\,\text{y}}$$

Express the ratio of T to Russell's estimate:

$$\frac{T}{T_{\text{Russell}}} = \frac{10^{484}\,\text{y}}{10^{6}\,\text{y}} = 10^{478}$$

or

$$T \approx \boxed{10^{478}T_{\text{Russell}}}$$

Thermal Properties and Processes

Conceptual Problems

1 • Why does the mercury level of a thermometer first decrease slightly when the thermometer is first placed in warm water?

Determine the Concept The glass bulb warms and expands first, before the mercury warms and expands.

2 • A large sheet of metal has a hole cut in the middle of it. When the sheet is heated, the area of the hole will (*a*) not change, (*b*) always increase, (*c*) always decrease, (*d*) increase if the hole is not in the exact center of the sheet, (*e*) decrease only if the hole is in the exact center of the sheet.

Determine the Concept The heating of the sheet causes the average separation of its molecules to increase. The consequence of this increased separation is that the area of the hole always increases. $\boxed{(b)}$ is correct.

3 • **[SSM]** Why is it a bad idea to place a tightly sealed glass bottle that is completely full of water, into your kitchen freezer in order to make ice?

Determine the Concept Water expands greatly as it freezes. If a sealed glass bottle full of water is placed in a freezer, as the water freezes there will be no room for the expansion to take place. The bottle will be broken.

4 • The windows of your physics laboratory are left open on a night when the temperature of the outside dropped well below freezing. A steel ruler and a wooden ruler were left on the window sill, and when you arrive in the morning they are both very cold. The coefficient of linear expansion of wood is about $5 \times 10^{-6}\ \text{K}^{-1}$. Which ruler should you use to make the most accurate length measurements? Explain your answer.

Determine the Concept You should use the wooden ruler. Because the coefficient of expansion for wood is about half that for metal, the metal ruler will have shrunk considerably more than will have the wooden ruler.

5 • Bimetallic strips are used both for thermostats and for electrical circuit breakers. A bimetallic strip consists of a pair of thin strips of metal that have different coefficients of linear expansion and are bonded together to form one doubly thick strip. Suppose a bimetallic strip is constructed out of one steel strip and one copper strip, and suppose the bimetallic strip is curled in the shape of a circular arc with the steel strip on the outside. If the temperature of the strip is decreased, will the strip straighten out or curl more tightly?

Determine the Concept The strip will curl more tightly. Because the coefficient of linear expansion for copper (17×10^{-6} K^{-1}) is greater than the coefficient of linear expansion for steel (11×10^{-6} K^{-1}), the length of the copper strip will decrease more than the length of the steel strip–resulting in a tighter curl.

6 • Metal A has a coefficient of linear expansion that is three times the coefficient of linear expansion of metal B. How do their coefficients of volume expansion β compare? (*a*) $\beta_A = \beta_B$, (*b*) $\beta_A = 3\beta_B$, (*c*) $\beta_A = 6\beta_B$, (*d*) $\beta_A = 9\beta_B$, (*e*) You cannot tell from the data given.

Determine the Concept We know that the coefficient of volume expansion is three times the coefficient of linear expansion and so can use this fact to express the ratio of β_A to β_B.

Express the coefficient of volume expansion of metal A in terms of its coefficient of linear expansion:

$$\beta_A = 3\alpha_A$$

Express the coefficient of volume expansion of metal B in terms of its coefficient of linear expansion:

$$\beta_B = 3\alpha_B$$

Dividing the first of these equations by the second yields:

$$\frac{\beta_A}{\beta_B} = \frac{3\alpha_A}{3\alpha_B} = \frac{\alpha_A}{\alpha_B}$$

Because $\boldsymbol{\alpha}_A = 3\boldsymbol{\alpha}_B$:

$$\frac{\beta_A}{\beta_B} = \frac{3\alpha_B}{\alpha_B} = 3 \Rightarrow \boxed{(b)} \text{ is correct.}$$

7 • The summit of Mount Rainier is 14 410 ft above sea level. Mountaineers say that you cannot hard boil an egg at the summit. This statement is true because at the summit of Mount Rainier (*a*) the air temperature is too low to boil water, (*b*) the air pressure is too low for alcohol fuel to burn, (*c*) the temperature of boiling water is not hot enough to hard boil the egg, (*d*) the oxygen content of the air is too low to support combustion, (*e*) eggs always break in climbers′ backpacks.

Determine the Concept Actually, an egg can be hard boiled, but it takes quite a bit longer than at sea level. $\boxed{(c)}$ is the best response.

8 • Which gases in Table 20-3 cannot be condensed by applying pressure at 20ºC? Explain your answer.

Determine the Concept Gases that cannot be liquefied by applying pressure at 20°C are those for which $T_c < 293$ K. These are He, Ar, Ne, H_2, O_2, NO.

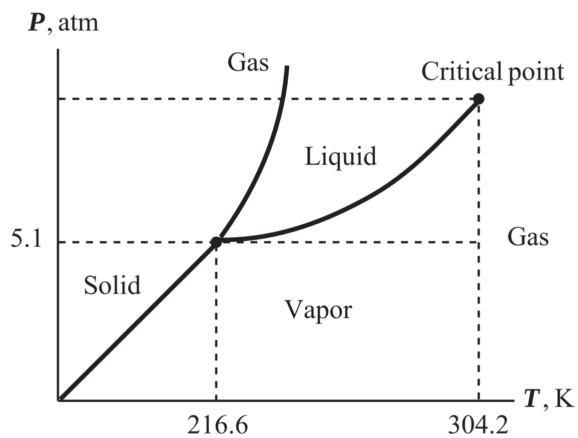
9 •• **[SSM]** The phase diagram in Figure 20-15 can be interpreted to yield information on how the boiling and melting points of water change with altitude. (*a*) Explain how this information can be obtained. (*b*) How might this information affect cooking procedures in the mountains?

Determine the Concept
(*a*) With increasing altitude, decreases; from curve OC, the temperature of the liquid-gas interface decreases as the pressure decreases, so the boiling temperature decreases. Likewise, from curve OB, the melting temperature increases with increasing altitude.

(*b*) Boiling at a lower temperature means that the cooking time will have to be increased.

10 •• Sketch a phase diagram for carbon dioxide using information from Section 20-3.

Determine the Concept The following phase diagram for carbon dioxide was constructed using information in Section 20-3.



11 •• Explain why the carbon dioxide on Mars is found in the solid state in the polar regions even though the atmospheric pressure at the surface of Mars is only about 1 percent of the atmospheric pressure at the surface of Earth.

Determine the Concept At very low pressures and temperatures, carbon dioxide can exist only as a solid or gas (or vapor above the gas). The atmosphere of Mars is 95 percent carbon dioxide. Mars, on average, is warm enough so that the atmosphere is mostly gaseous carbon dioxide. The polar regions are cold enough to enable solid carbon dioxide (dry ice) to exist, even at the low pressure.

12 •• Explain why decreasing the temperature of your house at night in winter can save money on heating costs. Why doesn't the cost of the fuel consumed to heat the house back to the daytime temperature in the morning equal

the savings realized by cooling it down in the evening and keeping it cool throughout the night?

Determine the Concept The amount of heat lost by the house is proportional to the difference between the temperature inside the house and that of the outside air. Hence, the rate at which the house loses heat (that must be replaced by the furnace) is greater at night when the temperature of the house is kept high than when it is allowed to cool down.

13 •• [SSM] Two solid cylinders made of materials A and B have the same lengths; their diameters are related by $d_A = 2d_B$. When the same temperature difference is maintained between the ends of the cylinders, they conduct heat at the same rate. Their thermal conductivities are therefore related by which of the following equations? (*a*) $k_A = k_B/4$, (*b*) $k_A = k_B/2$, (*c*) $k_A = k_B$, (*d*) $k_A = 2k_B$, (*e*) $k_A = 4k_B$

Picture the Problem The rate at which heat is conducted through a cylinder is given by $I = dQ/dt = kA\Delta T/\Delta x$ (see Equation 20-7) where A is the cross-sectional area of the cylinder.

The heat current in cylinder A is the same as the heat current in cylinder B:

$$I_A = I_B$$

Substituting for the heat currents yields:

$$k_A A_A \frac{\Delta T}{L} = k_B A_B \frac{\Delta T}{L} \Rightarrow k_A = k_B \frac{A_B}{A_A}$$

Because $d_A = 2d_B$:

$$k_A = k_B\left(\frac{A_B}{4A_B}\right) \Rightarrow k_A = \tfrac{1}{4}k_B$$

$\boxed{(a)}$ is correct.

14 •• Two solid cylinders made of materials A and B have the same diameter; their lengths are related by $L_A = 2L_B$. When the same temperature difference is maintained between the ends of the cylinders, they conduct heat at the same rate. Their thermal conductivities are therefore related by which of the following equations? (*a*) $k_A = k_B/4$, (*b*) $k_A = k_B/2$, (*c*) $k_A = k_B$, (*d*) $k_A = 2k_B$, (*e*) $k_A = 4k_B$.

Determine the Concept We can use the expression for the heat current in a conductor, Equation 20-7, to relate the heat current in each cylinder to its thermal conductivity, cross-sectional area, temperature difference, and length.

The heat current in cylinder A is the same as the heat current in cylinder B:

$$I_A = I_B$$

Substituting for the heat currents yields:

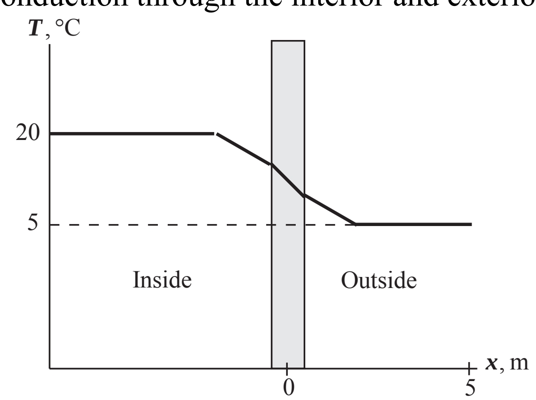
$$k_A A \frac{\Delta T}{L_A} = k_B A \frac{\Delta T}{L_B} \Rightarrow k_A = k_B \frac{L_A}{L_B}$$

Because $L_A = 2L_B$:

$$k_A = k_B \frac{2L_B}{L_B} = 2k_B \Rightarrow \boxed{(d)} \text{ is correct.}$$

15 •• If you feel the inside of a single pane window during a very cold day, it is cold, even though the room temperature can be quite comfortable. Assuming the room temperature is 20.0°C and the outside temperature is 5.0°C, Construct a plot of temperature versus position starting from a point 5.0 m in behind the window (inside the room) and ending at a point 5.0 m in front of the window. Explain the heat transfer mechanisms that occur along this path.

Determine the Concept The temperatures on both sides of the glass are almost the same. Because glass is an excellent conductor of heat, there need not be a huge temperature difference. Thus the temperature must drop quickly as you near the pane on the warm side and the same on the outside. This is sketched qualitatively in the following diagram. Convection and radiation are primarily responsible for heat transfer on the inside and outside, and it is mainly conduction through the glass. Conduction through the interior and exterior air is minimal.



16 •• During the thermal retrofitting of many older homes in California, it was found that the 3.5-in-deep spaces between the wallboards and the outer sheathing were filled with just air (no insulation). Filling the space with insulating material certainly reduces heating and cooling costs; although, the insulating material is a better conductor of heat than air is. Explain why adding the insulation is a good idea.

Determine the Concept The tradeoff is the reduction of convection cells between the walls by putting in the insulating material, versus a slight increase in conductivity. The net reduction in convection results in a higher R value.

Estimation and Approximation

17 •• [SSM] You are using a cooking pot to boil water for a pasta dish. The recipe calls for at least 4.0 L of water to be used. You fill the pot with 4.0 L of room temperature water and note that this amount of water filled the pot to the brim. Knowing some physics, you are counting on the volume expansion of the steel pot to keep all of the water in the pot while the water is heated to a boil. Is your assumption correct? Explain. If your assumption is not correct, how much water runs over the sides of the pot due to the thermal expansion of the water?

Determine the Concept The volume of water overflowing is the difference between the change in volume of the water and the change in volume of the pot. See Table 20-1 for the coefficient of volume expansion of water and the coefficient of linear expansion of steel.

Express the volume of water that overflows when the pot and the water are heated:

$$\begin{aligned} V_{\text{ovefrlow}} &= \Delta V_{H_2O} - \Delta V_{\text{pot}} \\ &= \beta_{H_2O} V_0 \Delta T - \beta_{\text{steel}} V_0 \Delta T \\ &= \left(\beta_{H_2O} - \beta_{\text{steel}}\right) V_0 \Delta T \end{aligned}$$

Because the coefficient of volume expansion of steel is three times its coefficient of linear expansion:

$$\beta_{\text{steel}} = 3\alpha_{\text{steel}}$$

Substituting for β_{H_2O} and β_{steel} yields:

$$V_{\text{overflow}} = \left(\alpha_{H_2O} - 3\alpha_{\text{steel}}\right) V_0 \Delta T$$

Substitute numerical values and evaluate V_{overflow} :

$$V_{\text{overflow}} = \left(0.207\times10^{-3}\ \text{K}^{-1} - 3\left(11\times10^{-6}\ \text{K}^{-1}\right)\right)(4.0\ \text{L})(100^\circ\text{C} - 20^\circ\text{C}) = \boxed{56\ \text{mL}}$$

Your assumption was not correct and 56 mL of water overflowed.

18 •• Liquid helium is stored in containers fitted with 7.00-cm-thick ″superinsulation″ consisting of numerous layers of very thin aluminized Mylar sheets. The rate of evaporation of liquid helium in a 200-L container is about 0.700 L per day when the container is stored at room temperature (20ºC). The density of liquid helium is 0.125 kg/L and the latent heat of vaporization is 21.0 kJ/kg. Estimate the thermal conductivity of the superinsulation.

Picture the Problem We can express the heat current through the insulation in terms of the rate of evaporation of the liquid helium and in terms of the temperature gradient across the superinsulation. Equating these equations will lead to an expression for the thermal conductivity *k* of the superinsulation. Note that the boiling temperature of liquid helium is 4.2 K.

Express the heat current in terms of the rate of evaporation of the liquid helium:

$$I = L_\text{v}\frac{dm}{dt}$$

Express the heat current in terms of the temperature gradient across the superinsulation and the conductivity of the superinsulation:

$$I = kA\frac{\Delta T}{\Delta x}$$

Equate these expressions and solve for k to obtain:

$$k = \frac{L_\text{v}\Delta x\dfrac{dm}{dt}}{A\Delta T}$$

Using the definition of density, express the rate of loss of liquid helium:

$$\frac{dm}{dt} = \rho\frac{dV}{dt}$$

Substitute for $\frac{dm}{dt}$ to obtain:

$$k = \frac{L_\text{v}\Delta x\rho\dfrac{dV}{dt}}{A\Delta T}$$

Express the ratio of the area of the spherical container to its volume:

$$\frac{A}{V} = \frac{4\pi r^2}{\frac{4}{3}\pi r^3} \Rightarrow A = \sqrt[3]{36\pi V^2}$$

Substituting for A yields:

$$k = \frac{L_\text{v}\Delta x\rho\dfrac{dV}{dt}}{\sqrt[3]{36\pi V^2}\,\Delta T}$$

Substitute numerical values and evaluate k:

$$k = \frac{\left(21.0\dfrac{\text{kJ}}{\text{kg}}\right)\left(7.00\times10^{-2}\text{ m}\right)\left(125\dfrac{\text{kg}}{\text{m}^3}\right)\left(\dfrac{0.700\times10^{-3}\text{ m}^3}{86400\text{s}}\right)}{\sqrt[3]{36\pi\left(200\times10^{-3}\text{ m}^3\right)^2}\left(289\text{K}\right)} = \boxed{3.12\times10^{-6}\ \frac{\text{W}}{\text{m}\cdot\text{K}}}$$

19 •• [SSM] Estimate the thermal conductivity of human skin.

Picture the Problem We can use the thermal current equation for the thermal conductivity of the skin. If we model a human body as a rectangular parallelepiped that is 1.5 m high × 7 cm thick × 50 cm wide, then its surface area is about 1.8 m^2. We'll also assume that a typical human, while resting, produces energy at the rate of 120 W, that normal internal and external temperatures are 33°C and 37°C, respectively, and that an average skin thickness is 1.0 mm.

Use the thermal current equation to express the rate of conduction of thermal energy:

$$I = kA\frac{\Delta T}{\Delta x} \Rightarrow k = \frac{I}{A\frac{\Delta T}{\Delta x}}$$

Substitute numerical values and evaluate *k*:

$$k = \frac{120\,\text{W}}{\left(1.8\,\text{m}^2\right)\frac{37°\text{C} - 33°\text{C}}{1.0\times10^{-3}\,\text{m}}} = \boxed{17\frac{\text{mW}}{\text{m}\cdot\text{K}}}$$

20 •• You are visiting Finland with a college friend and have met some Finnish friends. They talk you into taking part in a traditional Finnish after-sauna exercise which consists of leaving the sauna, wearing only a bathing suit, and running out into the mid-winter Finnish air. Estimate the rate at which you initially lose energy to the cold air. Compare this rate of initial energy loss to the resting metabolic rate of a typical human under normal temperature conditions. Explain the difference.

Picture the Problem We can use the Stefan-Boltzmann law to estimate the rate at which you lose energy when you first step out of the sauna. If we model a human body as a rectangular parallelepiped that is 1.5 m high × 7 cm thick × 50 cm wide, then its surface area is about 1.8 m^2. Assume that your skin temperature is initially 37°C (310 K), that the mid-winter outside temperature is −10°C (263 K), and that the emissivity of your skin is 1.

Use the Stefan-Boltzmann law to express the net rate at which you radiate energy to the cold air:

$$P_{\text{net}} = \varepsilon\sigma A\left(T_{\text{skin}}^4 - T_{\text{air}}^4\right)$$

Substitute numerical values and evaluate P_{net}:

$$P_{\text{net}} = (1)\left(5.670\times10^{-8}\,\frac{\text{W}}{\text{m}^2\cdot\text{K}^4}\right)\left(1.8\,\text{m}^2\right)\left((310\,\text{K})^4 - (263\,\text{K})^4\right) = \boxed{450\,\text{W}}$$

This result is almost four times greater than the basal metabolic rate of 120 W. We can understand the difference in terms of the temperature of your skin when you first step out of the sauna and the fact that radiation loses are dependent on the fourth power of the absolute temperature.

Remarks: The emissivity of your skin is, in fact, very close to 1.

21 •• Estimate the rate of heat conduction through a 2.0-in-thick wooden door during a cold winter day in Minnesota. Include the brass doorknob. What is the ratio of the heat that escapes through the doorknob to the heat that escapes through the whole door? What is the total overall *R*-factor for the door, including the knob? The thermal conductivity of brass is $85\,\text{W}/(\text{m}\cdot\text{K})$.

Picture the Problem We can use the thermal current equation (Equation 20-7) to estimate the rate of heat loss through the door and its knob. We'll assume that the door is made of oak with an area of 2.0 m^2, that the knob is made of brass, that the conducting path has a diameter of 3.0 cm, and that the inside temperature is 20°C. Take the outside temperature to be −20°C. The reciprocal of the equivalent R-factor is the sum of the reciprocals of the R-values of the door and the knob.

The total thermal current through the door is the sum of the thermal currents through the door and the knob:

$$I_{\text{tot}} = I_{\text{door}} + I_{\text{knob}} = \frac{k_{\text{door}}A_{\text{door}}\Delta T}{\Delta x_{\text{door}}} + \frac{k_{\text{knob}}A_{\text{knob}}\Delta T}{\Delta x_{\text{knob}}}$$

Assume that $\Delta \boldsymbol{x}_{\text{door}} = \Delta \boldsymbol{x}_{\text{knob}} = \Delta \boldsymbol{x}$ to obtain:

$$I_{\text{tot}} = \left(k_{\text{door}}A_{\text{door}} + k_{\text{knob}}A_{\text{knob}}\right)\frac{\Delta T}{\Delta x}$$

Substitute numerical values and evaluate I_{tot}:

$$I_{\text{tot}} = \left[\left(0.15\frac{\text{W}}{\text{m}\cdot\text{K}}\right)\left(2.0\ \text{m}^2\right) + \left(85\frac{\text{W}}{\text{m}\cdot\text{K}}\right)\frac{\pi}{4}\left(3.0\times10^{-2}\ \text{m}\right)^2\right]\frac{20°\text{C} - (-20°\text{C})}{(2.0\ \text{in})\left(\dfrac{1\ \text{m}}{39.37\ \text{in}}\right)}$$

$$= \boxed{0.28\ \text{kW}}$$

Express the ratio of the thermal currents through the knob and the door:

$$\frac{I_{\text{knob}}}{I_{\text{door}}} = \frac{k_{\text{door}}A_{\text{door}}\left(\dfrac{\Delta T}{\Delta x}\right)_{\text{door}}}{k_{\text{knob}}A_{\text{knob}}\left(\dfrac{\Delta T}{\Delta x}\right)_{\text{knob}}}$$

Because the temperature difference across the door and the knob are the same and we've assumed that the thickness of the door and length of the knob are the same:

$$\frac{I_{\text{knob}}}{I_{\text{door}}} = \frac{k_{\text{door}}A_{\text{door}}}{k_{\text{knob}}A_{\text{knob}}}$$

Substitute numerical values to obtain:

$$\frac{I_{\text{knob}}}{I_{\text{door}}} = \frac{\left(0.15\dfrac{\text{W}}{\text{m}\cdot\text{K}}\right)\left(2.0\ \text{m}^2\right)}{\left(85\dfrac{\text{W}}{\text{m}\cdot\text{K}}\right)\dfrac{\pi}{4}\left(3.0\times10^{-2}\ \text{m}\right)^2} = \boxed{5.0}$$

Relate the equivalent R-factor to the R-factors of the door and knob;

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R_{\text{door}}} + \frac{1}{R_{\text{knob}}}$$

Substitute for R_{door} and R_{knob} to obtain:

$$\frac{1}{R_{eq}} = \frac{1}{\dfrac{\Delta x}{k_{door}A_{door}}} + \frac{1}{\dfrac{\Delta x}{k_{knob}A_{knob}}} = \frac{k_{door}A_{door} + k_{knob}A_{knob}}{\Delta x}$$

Solving for R_{eq} yields:

$$R_{eq} = \frac{\Delta x}{k_{door}A_{door} + k_{knob}A_{knob}}$$

Substitute numerical values and evaluate R_{eq}:

$$R_{eq} = \frac{(2.0\text{ in})\left(\dfrac{1\text{ m}}{39.37\text{ in}}\right)}{\left(0.15\dfrac{\text{W}}{\text{m}\cdot\text{K}}\right)(2.0\text{ m}^2) + \left(85\dfrac{\text{W}}{\text{m}\cdot\text{K}}\right)\dfrac{\pi}{4}\left(3.0\times10^{-2}\text{ m}\right)^2} = \boxed{0.14\frac{\text{K}}{\text{W}}}$$

22 •• Estimate the effective emissivity of Earth, given the following information. The solar constant, which is the intensity of radiation incident on Earth from the Sun, is about 1.37 kW/m^2. Seventy percent of this energy is absorbed by Earth, and Earth's average surface temperature is 288 K. (Assume that the effective area that is absorbing the light is πR^2, where R is Earth's radius, while the blackbody-emission area is $4\pi R^2$.)

Picture the Problem The amount of heat radiated by Earth must equal the solar flux from the Sun, or else the temperature on Earth would continually increase. The emissivity of Earth is related to the rate at which it radiates energy into space by the Stefan-Boltzmann law $P_r = e\sigma AT^4$.

Using the Stefan-Boltzmann law, express the rate at which Earth radiates energy as a function of its emissivity e and temperature T:

$$P_r = e\sigma A'T^4 \Rightarrow e = \frac{P_r}{\sigma A'T^4}$$

where A' is the surface area of Earth.

Use its definition to express the intensity of the radiation received by Earth:

$$I = \frac{P_{absorbed}}{A}$$

where A is the cross-sectional area of Earth.

For 70% absorption of the Sun's radiation incident on Earth:

$$I = \frac{(0.70)P_r}{A}$$

Substitute for P_r and A in the expression for e and simplify to

$$e = \frac{(0.70)AI}{\sigma A'T^4} = \frac{(0.70)\pi R^2 I}{4\pi R^2\sigma T^4} = \frac{(0.70)I}{4\sigma T^4}$$

obtain:

Substitute numerical values and evaluate e:

$$e = \frac{(0.70)(1.37\,\text{kW/m}^2)}{4(5.670\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(288\,\text{K})^4} = \boxed{0.61}$$

23 •• Black holes are highly condensed remnants of stars. Some black holes, together with a normal star, form binary systems. In such systems the black hole and the normal star orbit about the center of mass of the system. One way black holes can be detected from Earth is by observing the frictional heating of the atmospheric gases from the normal star that fall into the black hole. These gases can reach temperatures greater than 1.0×10^6 K. Assuming that the falling gas can be modeled as a blackbody radiator, estimate λ_{max} for use in an astronomical detection of a black hole. (Remark: This is in the X-ray region of the electromagnetic spectrum.)

Picture the Problem The wavelength at which maximum power is radiated by the gas falling into a black hole is related to its temperature by Wien's displacement law.

Wien's displacement law relates the wavelength at which maximum power is radiated by the gas to its temperature:

$$\lambda_{\text{max}} = \frac{2.898\,\text{mm}\cdot\text{K}}{T}$$

Substitute for T and evaluate λ_{max}:

$$\lambda_{\text{max}} = \frac{2.898\,\text{mm}\cdot\text{K}}{1.0\times10^6\ \text{K}} = \boxed{2.9\,\text{nm}}$$

24 ••• Your cabin in northern Michigan has walls that consist of pine logs that have average thicknesses of about 20 cm. You decide to finish the interior of the cabin to improve the look and to increase the insulation of the exterior walls. You choose to buy insulation with an R-factor of 31 to cover the walls. In addition, you cover the insulation with 1.0-in-thick gypsum wallboard. Assuming heat transfer is only due to conduction, estimate the ratio of thermal current through the walls during a cold winter night before the renovation to the thermal current through the walls following the renovation.

Picture the Problem We can use the thermal current equation to find the thermal current per square meter through the walls of the cabin both before and after the walls have been insulated. See Table 20-5 for the R-factor of gypsum wallboard and Table 20-4 for the thermal conductivity of white pine.

The rate at which heat is conducted through the walls is given by the thermal current equation:

$$I_{\text{before}} = k_{\text{before}} A \frac{\Delta T}{\Delta x} = \frac{\Delta T}{R_{\text{before}}}$$

With the insulation in place:

$$I_{\text{after}} = k_{\text{after}} A \frac{\Delta T}{\Delta x} = \frac{\Delta T}{R_{\text{after}}}$$

Divide the second of these equations by the first to obtain:

$$\frac{I_{\text{after}}}{I_{\text{before}}} = \frac{\dfrac{\Delta T}{R_{\text{after}}}}{\dfrac{\Delta T}{R_{\text{before}}}} = \frac{R_{\text{before}}}{R_{\text{after}}}$$

R_{before} is the R-factor for pine and R_{after} is the sum of the R-factors for pine, the insulating material, and the gypsum board:

$$R_{\text{before}} = R_{\text{pine}}$$

and

$$R_{\text{after}} = R_{\text{eq}} = R_{\text{pine}} + R_{31} + R_{\text{gypsum}}$$

Substitute for R_{before} and R_{after} to obtain:

$$\frac{I_{\text{after}}}{I_{\text{before}}} = \frac{R_{\text{pine}}}{R_{\text{pine}} + R_{31} + R_{\text{gypsum}}}$$

Because $R_{\text{pine}} = \dfrac{\Delta x}{k_{\text{pine}}}$:

$$\frac{I_{\text{after}}}{I_{\text{before}}} = \frac{\dfrac{\Delta x}{k_{\text{pine}}}}{\dfrac{\Delta x}{k_{\text{pine}}} + R_{31} + R_{\text{gypsum}}}$$

Substitute numerical values and evaluate the ratio $I_{\text{after}} / I_{\text{before}}$:

$$\frac{I_{\text{after}}}{I_{\text{before}}} = \frac{\dfrac{20\,\text{cm} \times \dfrac{1\,\text{in}}{2.54\,\text{cm}}}{0.78\,\dfrac{\text{Btu}\cdot\text{in}}{\text{h}\cdot\text{ft}^2\cdot\text{F}^\circ}}}{\dfrac{20\,\text{cm} \times \dfrac{1\,\text{in}}{2.54\,\text{cm}}}{0.78\,\dfrac{\text{Btu}\cdot\text{in}}{\text{h}\cdot\text{ft}^2\cdot\text{F}^\circ}} + 31\,\dfrac{\text{h}\cdot\text{ft}^2\cdot\text{F}^\circ}{\text{Btu}} + \dfrac{1\,\text{in}}{0.375\,\text{in}} \times 0.32\,\dfrac{\text{h}\cdot\text{ft}^2\cdot\text{F}^\circ}{\text{Btu}}} = \boxed{24\%}$$

25 ••• [SSM] You are in charge of transporting a liver from New York, New York to Los Angeles, California for a transplant surgery. The liver is kept cold in a Styrofoam ice chest initially filled with 1.0 kg of ice. It is crucial that the liver temperature is never warmer than 5.0°C. Assuming the trip from the hospital in New York to the hospital in Los Angeles takes 7.0 h, estimate the R-value the Styrofoam walls of the ice chest must have.

Picture the Problem The R factor is the thermal resistance per unit area of a slab of material. We can use the thermal current equation to express the thermal resistance of the styrofoam in terms of the maximum amount of heat that can enter the chest in 7.0 h without raising the temperature above 5.0°C. We'll

assume that the surface area of the ice chest is 1.0 m^2 and that the ambient temperature is 25°C

The R-factor needed for the styrofoam walls of the ice chest is the product of their thermal resistance and area:

$$R_f = RA \qquad (1)$$

Use the thermal current equation to express R:

$$R = \frac{\Delta T}{I} = \frac{\Delta T}{\frac{Q_{tot}}{\Delta t}} = \frac{\Delta T \Delta t}{Q_{tot}}$$

Substitute for R in equation (1) to obtain:

$$R_f = \frac{A\Delta T\Delta t}{Q_{tot}}$$

The total heat entering the chest in 7 h is given by:

$$Q_{tot} = Q_{\underset{\text{ice}}{\text{melt}}} + Q_{\underset{\text{ice water}}{\text{warm}}}$$
$$= m_{ice}L_f + m_{ice}c_{H_2O}\Delta T_{H_2O}$$

Substitute for Q_{tot} and simplify to obtain:

$$R_f = \frac{A\Delta T\Delta t}{m_{ice}\left(L_f + c_{H_2O}\Delta T_{H_2O}\right)}$$

Substitute numerical values and evaluate R_f:

$$R_f = \frac{\left(1.0\,\text{m}^2 \times \frac{1\,\text{ft}^2}{9.29\times10^{-2}\,\text{m}^2}\right)\left(20\,\text{C}^\circ \times \frac{9\,\text{F}^\circ}{5\,\text{C}^\circ}\right)(7\,\text{h})\left(\frac{1054.35\,\text{J}}{\text{Btu}}\right)}{(1\,\text{kg})\left(333.5\frac{\text{kJ}}{\text{kg}} + \left(4.18\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(5\,\text{C}^\circ)\right)} \approx \boxed{8\frac{\text{F}^\circ\cdot\text{h}\cdot\text{ft}^2}{\text{Btu}}}$$

Thermal Expansion

26 •• You have inherited your grandfather's grandfather clock that was calibrated when the temperature of the room was 20ºC. Assume that the pendulum consists of a thin brass rod of negligible mass with a compact heavy bob at its end. (*a*) During a hot day, the temperature is 30ºC, does the clock run fast or slow? Explain. (*b*) How much time does it gain or lose during this day?

Picture the Problem We can determine whether the clock runs fast or slow from the expression for the period of a simple pendulum and the dependence of its length on the temperature. We can use the expression for the period of a simple pendulum and the equation describing its length as a function of temperature to find the time gained or lost in a 24-h period.

(*a*) Express the period of the pendulum in terms of its length:

$$T_P = 2\pi\sqrt{\frac{L}{g}}$$

Because $T_P \propto \sqrt{L}$ and L is temperature dependent, the clock runs slow.

(*b*) The period of the pendulum when the temperature is 20°C is given by:

$$T_{20} = 2\pi\sqrt{\frac{L_{20}}{g}} \qquad (1)$$

When the temperature increases to 30°C, the period of the pendulum increases due to the increase in its length:

$$T = 2\pi\sqrt{\frac{L}{g}} = 2\pi\sqrt{\frac{L_{20}(1+\alpha\Delta t_C)}{g}}$$
$$= T_{20}\sqrt{1+\alpha\Delta t_C}$$

The daily fractional gain or loss is given by :

$$\frac{\Delta\tau}{\tau} = \frac{\Delta T}{T_{20}} = \frac{T - T_{20}}{T_{20}}$$

Substituting for T and simplifying yields:

$$\frac{\Delta\tau}{\tau} = \frac{T_{20}\sqrt{1+\alpha\Delta t_C} - T_{20}}{T_{20}}$$
$$= \sqrt{1+\alpha\Delta t_C} - 1$$

Solve for $\Delta\tau$ to obtain:

$$\Delta\tau = \left(\sqrt{1+\alpha\Delta t_C} - 1\right)\tau$$

Substitute numerical values and $\Delta\tau$:

$$\Delta\tau = \left(\sqrt{1+\left(19\times10^{-6}\,\text{K}^{-1}\right)\left(30°\text{C} - 20°\text{C}\right)} - 1\right)\left(24\,\text{h}\times\frac{3600\,\text{s}}{\text{h}}\right) = \boxed{8.2\,\text{s}}$$

27 •• [SSM] You need to fit a copper collar tightly around a steel shaft that has a diameter of 6.0000 cm at 20ºC. The inside diameter of the collar at that temperature is 5.9800 cm. What temperature must the copper collar have so that it will just slip on the shaft, assuming the shaft itself remains at 20ºC?

Picture the Problem Because the temperature of the steel shaft does not change, we need consider just the expansion of the copper collar. We can express the required temperature in terms of the initial temperature and the change in temperature that will produce the necessary increase in the diameter D of the copper collar. This increase in the diameter is related to the diameter at 20°C and the increase in temperature through the definition of the coefficient of linear expansion.

Express the temperature to which the

$$T = T_i + \Delta T$$

copper collar must be raised in terms of its initial temperature and the increase in its temperature:

Apply the definition of the coefficient of linear expansion to express the change in temperature required for the collar to fit on the shaft:

$$\Delta T = \frac{\left(\dfrac{\Delta D}{D}\right)}{\alpha} = \frac{\Delta D}{\alpha D}$$

Substitute for ΔT to obtain:

$$T = T_{\text{i}} + \frac{\Delta D}{\alpha D}$$

Substitute numerical values and evaluate T:

$$T = 20°\text{C} + \frac{6.0000\,\text{cm} - 5.9800\,\text{cm}}{\left(17\times10^{-6}\,\text{K}^{-1}\right)\left(5.9800\,\text{cm}\right)}$$
$$= \boxed{220°\text{C}}$$

28 •• You have a copper collar and a steel shaft. At 20°C, the collar has an inside diameter of 5.9800 cm and the steel shaft has diameter of 6.0000 cm. The copper collar was heated. When its inside diameter exceeded 6.0000 cm is was slipped on the shaft. The collar fitted tightly on the shaft after they cooled to room temperature. Now, several years later, you need to remove the collar from the shaft. To do this you heat them both until you can just slip the collar off the shaft. What temperature must the collar have so that the collar will just slip off the shaft?

Picture the Problem Because the temperatures of both the steel shaft and the copper collar change together, we can find the temperature change required for the collar to fit the shaft by equating their diameters for a temperature increase ΔT. These diameters are related to their diameters at 20°C and the increase in temperature through the definition of the coefficient of linear expansion.

Express the temperature to which the collar and the shaft must be raised in terms of their initial temperature and the increase in their temperature:

$$T = T_{\text{i}} + \Delta T \qquad (1)$$

Express the diameter of the steel shaft when its temperature has been increased by ΔT:

$$D_{\text{steel}} = D_{\text{steel,20°C}}\left(1 + \alpha_{\text{steel}}\Delta T\right)$$

Express the diameter of the copper collar when its temperature has been

$$D_{\text{Cu}} = D_{\text{Cu,20°C}}\left(1 + \alpha_{\text{Cu}}\Delta T\right)$$

increased by ΔT:

If the collar is to fit over the shaft when the temperature of both has been increased by ΔT:

$$D_{\text{Cu,20°C}}(1+\alpha_{\text{Cu}}\Delta T) = D_{\text{steel,20°C}}(1+\alpha_{\text{steel}}\Delta T)$$

Solving for ΔT yields:

$$\Delta T = \frac{D_{\text{steel,20°C}} - D_{\text{Cu,20°C}}}{D_{\text{Cu,20°C}}\alpha_{\text{Cu}} - D_{\text{steel,20°C}}\alpha_{\text{steel}}}$$

Substitute in equation (1) to obtain:

$$T = T_{\text{i}} + \frac{D_{\text{steel,20°C}} - D_{\text{Cu,20°C}}}{D_{\text{Cu,20°C}}\alpha_{\text{Cu}} - D_{\text{steel,20°C}}\alpha_{\text{steel}}}$$

Substitute numerical values and evaluate T:

$$T = 20°\text{C} + \frac{6.0000\,\text{cm} - 5.9800\,\text{cm}}{(5.9800\,\text{cm})(17\times10^{-6}\,/\text{K}) - (6.0000\,\text{cm})(11\times10^{-6}\,/\text{K})} = \boxed{580°\text{C}}$$

29 •• A container is filled to the brim with 1.4 L of mercury at 20ºC. As the temperature of container and mercury is increased to 60ºC, a total of 7.5 mL of mercury spill over the brim of the container. Determine the linear expansion coefficient of the material that makes up the container.

Picture the Problem The linear expansion coefficient of the container is one-third its coefficient of volume expansion. We can relate the changes in volume of the mercury and the container to their initial volumes, temperature change, and coefficients of volume expansion, and, because we know the amount of spillage, obtain an equation that we can solve for β_{c}.

Relate the linear expansion coefficient of the container to its coefficient of volume expansion:

$$\alpha_{\text{c}} = \tfrac{1}{3}\beta_{\text{c}} \qquad (1)$$

Express the difference in the change in the volume of the mercury and the container in terms of the spillage:

$$\Delta V_{\text{Hg}} - \Delta V_{\text{c}} = 7.5\,\text{mL} \qquad (2)$$

Express ΔV_{Hg} using the definition of the coefficient of volume expansion:

$$\Delta V_{\text{Hg}} = \beta_{\text{Hg}} V_{\text{Hg}} \Delta T$$

Express ΔV_{c} using the definition of the coefficient of volume expansion:

$$\Delta V_{\text{c}} = \beta_{\text{c}} V_{\text{c}} \Delta T$$

Substitute for ΔV_{Hg} and ΔV_c in equation (2) to obtain:

$$\beta_{Hg}V_{Hg}\Delta T - \beta_c V_c \Delta T = 7.5\,\text{mL}$$

Solving for β_c yields:

$$\beta_c = \frac{\beta_{Hg}V_{Hg}\Delta T - 7.5\,\text{mL}}{V_c\Delta T}$$

or, because $V = V_{Hg} = V_c$,

$$\beta_c = \frac{\beta_{Hg}V\Delta T - 7.5\,\text{mL}}{V\Delta T} = \beta_{Hg} - \frac{7.5\,\text{mL}}{V\Delta T}$$

Substitute for β_c in equation (1) to obtain:

$$\alpha_c = \tfrac{1}{3}\beta_{Hg} - \frac{7.5\,\text{mL}}{3V\Delta T} = \alpha_{Hg} - \frac{7.5\,\text{mL}}{3V\Delta T}$$

Substitute numerical values and evaluate α_c:

$$\alpha_c = \tfrac{1}{3}\left(0.18\times10^{-3}\,\text{K}^{-1}\right) - \frac{7.5\,\text{mL}}{3(1.4\,\text{L})(40\,\text{K})} = \boxed{15\times10^{-6}\,\text{K}^{-1}}$$

30 •• A car has a 60.0-L steel gas tank filled to the brim with 60.0-L of gasoline when the temperature of the outside is 10ºC. The coefficient of volume expansion for gasoline at 20°C is 0.950 × 10^{-3} K⁻1. How much gasoline spills out of the tank when the outside temperature increases to 25ºC? Take the expansion of the steel tank into account.

Picture the Problem The amount of gas that spills is the difference between the change in the volume of the gasoline and the change in volume of the tank. We can find this difference by expressing the changes in volume of the gasoline and the tank in terms of their common volume at 10°C, their coefficients of volume expansion, and the change in the temperature.

Express the spill in terms of the change in volume of the gasoline and the change in volume of the tank:

$$V_{spill} = \Delta V_{gasoline} - \Delta V_{tank}$$

Relate $\Delta V_{gasoline}$ to the coefficient of volume expansion for gasoline:

$$\Delta V_{gas} = \beta_{gasoline}V\Delta T$$

Relate ΔV_{tank} to the coefficient of linear expansion for steel:

$$\Delta V_{\text{tank}} = \beta_{\text{tank}} V \Delta T$$

or, because $\beta_{\text{steel}} = 3\alpha_{\text{steel}}$,

$$\Delta V_{\text{tank}} = 3\alpha_{\text{steel}} V \Delta T$$

Substitute for $\Delta V_{\text{gasoline}}$ and ΔV_{tank} and simplify to obtain:

$$\begin{aligned} V_{\text{spill}} &= \beta_{\text{gas}} V \Delta T - 3\alpha_{\text{steel}} V \Delta T \\ &= V \Delta T \left(\beta_{\text{gasoline}} - 3\alpha_{\text{steel}}\right) \end{aligned}$$

Substitute numerical values and evaluate V_{spill}:

$$V_{\text{spill}} = (60.0\,\text{L})(25°\text{C} - 10°\text{C})\left[0.950\times10^{-3}\,\text{K}^{-1} - 3\left(11\times10^{-6}\,\text{K}^{-1}\right)\right] \approx \boxed{0.8\,\text{L}}$$

31 ••• What is the tensile stress in the copper collar of Problem 27 when its temperature returns to 20ºC?

Picture the Problem We can use the definition of Young's modulus to express the tensile stress in the copper in terms of the strain it undergoes as its temperature returns to 20°C. We can show that $\Delta L/L$ for the circumference of the collar is the same as $\Delta d/d$ for its diameter.

Using Young's modulus, relate the stress in the collar to its strain:

$$\text{Stress} = Y \times \text{Strain} = Y \frac{\Delta L}{L_{20°\text{C}}}$$

where $L_{20°\text{C}}$ is the circumference of the collar at 20°C.

Express the circumference of the collar at the temperature at which it fits over the shaft:

$$L_T = \pi d_T$$

Express the circumference of the collar at 20 °C:

$$L_{20°\text{C}} = \pi d_{20°\text{C}}$$

Substitute for L_T and $L_{20°\text{C}}$ and simplify to obtain:

$$\begin{aligned} \text{Stress} &= Y \frac{\pi d_T - \pi d_{20°\text{C}}}{\pi d_{20°\text{C}}} \\ &= Y \frac{d_T - d_{20°\text{C}}}{d_{20°\text{C}}} \end{aligned}$$

Substitute numerical values and evaluate the stress:

$$\text{Stress} = \left(11\times10^{-10}\ \text{N/m}^2\right)\frac{6.0000\,\text{cm} - 5.9800\,\text{cm}}{5.9800\,\text{cm}} = \boxed{3.7\times10^{-12}\ \text{N/m}^2}$$

The van der Waals Equation, Liquid-Vapor Isotherms, and Phase Diagrams

32 • (*a*) Calculate the volume of 1.00 mol of an ideal gas at a temperature of 100ºC and a pressure of 1.00 atm. (*b*) Calculate the temperature at which 1.00 mol of steam at a pressure of 1.00 atm has the volume calculated in Part (*a*). Use $a = 0.550\ \text{Pa}\cdot\text{m}^6/\text{mol}^2$ and $b = 30.0\ \text{cm}^3/\text{mol}$.

Picture the Problem We can apply the ideal-gas law to find the volume of 1.00 mol of steam at 100°C and a pressure of 1.00 atm and then use the van der Waals equation to find the temperature at which the steam will this volume.

(*a*) Solving the ideal-gas law for the volume gives:

$$V = \frac{nRT}{P}$$

Substitute numerical values and evaluate V:

$$V = \frac{(1.00\text{mol})(8.314\,\text{J/mol}\cdot\text{K})(373\,\text{K})}{1.00\,\text{atm}\times\dfrac{101.325\,\text{kPa}}{\text{atm}}} = 3.06\times10^{-2}\ \text{m}^3\times\frac{1\,\text{L}}{10^{-3}\ \text{m}^3} = \boxed{30.6\,\text{L}}$$

(*b*) Solve van der Waals equation for T to obtain:

$$T = \frac{\left(P + \dfrac{an^2}{V^2}\right)(V - bn)}{nR}$$

Substitute numerical values and evaluate T:

$$T = \left(101.325\,\text{kPa} + \frac{\left(0.550\,\text{Pa}\cdot\text{m}^6/\text{mol}^2\right)(1.00\,\text{mol})^2}{\left(3.06\times10^{-2}\ \text{m}^3\right)^2}\right) \times\frac{3.06\times10^{-2}\ \text{m}^3 - \left(30.0\times10^{-6}\ \text{m}^3/\text{mol}\right)(1.00\,\text{mol})}{(1.00\,\text{mol})\,(8.314\,\text{J/mol}\cdot\text{K})} = \boxed{375\,\text{K}}$$

33 •• **[SSM]** Using Figure 20-16, find the following quantities. (*a*) The temperature at which water boils on a mountain where the atmospheric pressure is 70.0 kPa, (*b*) the temperature at which water boils in a container where the pressure inside the container is 0.500 atm, and (*c*) the pressure at which water boils at 115ºC.

Picture the Problem Consulting Figure 20-16, we see that:

(*a*) At 70.0 kPa, water boils at approximately $\boxed{90°\text{C}}$.

(*b*) At 0.500 atm (about 51 kPa), water boils at approximately $\boxed{78°\text{C}}$.

(*c*) The pressure at which water boils at 115°C is approximately $\boxed{127\,\text{kPa}}$.

34 •• The van der Waals constants for helium are $a = 0.03412\ \text{L}^2\cdot\text{atm/mol}^2$ and $b = 0.0237$ L/mol. Use these data to find the volume in cubic centimeters occupied by one helium atom. Then, estimate the radius of the helium atom.

Picture the Problem Assume that a helium atom is spherical. Then we can find its volume from the van der Waals equation and its radius from $V = \frac{4}{3}\pi r^3$.

In the van der Waals equation, b is the volume of 1 mol of molecules. For He, 1 molecule = 1 atom. Use Avogadro's number to express b in cm^3/atom:

$$b = \frac{\left(0.0237\,\frac{\text{L}}{\text{mol}}\right)\left(10^3\,\frac{\text{cm}^3}{\text{L}}\right)}{6.022\times10^{23}\,\frac{\text{atoms}}{\text{mol}}} = \boxed{3.94\times10^{-23}\,\frac{\text{cm}^3}{\text{atom}}}$$

The volume of a spherical helium atom is given by:

$$V = \tfrac{4}{3}\pi r^3 \Rightarrow r = \sqrt[3]{\frac{3V}{4\pi}} = \sqrt[3]{\frac{3b}{4\pi}}$$

Substitute numerical values and evaluate r:

$$r = \sqrt[3]{\frac{3\left(3.94\times10^{-23}\ \text{cm}^3\right)}{4\pi}} = \boxed{0.211\text{nm}}$$

Conduction

35 • **[SSM]** A 20-ft × 30-ft slab of insulation has an R factor of 11. At what rate is heat conducted through the slab if the temperature on one side is a constant 68ºF and the temperature of the other side is a constant 30ºF?

Picture the Problem We can use its definition to express the thermal current in the slab in terms of the temperature differential across it and its thermal resistance and use the definition of the R factor to express I as a function of ΔT, the cross-sectional area of the slab, and R_f.

Express the thermal current through the slab in terms of the temperature difference across it and its thermal resistance:

$$I = \frac{\Delta T}{R}$$

Substitute to express R in terms of the insulation's R factor:

$$I = \frac{\Delta T}{R_f / A} = \frac{A\Delta T}{R_f}$$

Substitute numerical values and evaluate I:

$$I = \frac{(20\,\text{ft})(30\,\text{ft})(68°\text{F} - 30°\text{F})}{11\dfrac{\text{h}\cdot\text{ft}^2\cdot\text{F}°}{\text{Btu}}} = \boxed{2.1\frac{\text{kBtu}}{\text{h}}}$$

36 •• A copper cube and an aluminum, cube each with 3.00-cm-long edges, are arranged as shown in Figure 20-17. Find (*a*) the thermal resistance of each cube, (*b*) the thermal resistance of the two-cube combination, (*c*) the thermal current I, and (*d*) the temperature at the interface of the two cubes.

Picture the Problem We can use $R = \Delta x/kA$ to find the thermal resistance of each cube and the fact that they are in series to find the thermal resistance of the two-cube system. We can use $I = \Delta T/R$ to find the thermal current through the cubes and the temperature at their interface. See Table 20-4 for the thermal conductivities of copper and aluminum.

(*a*) Using its definition, express the thermal resistance of each cube:

$$R = \frac{\Delta x}{kA}$$

Substitute numerical values and evaluate the thermal resistance of the copper cube:

$$R_{Cu} = \frac{3.00\,\text{cm}}{\left(401\dfrac{\text{W}}{\text{m}\cdot\text{K}}\right)(3.00\,\text{cm})^2} = 0.08313\,\text{K/W} = \boxed{0.0831\,\text{K/W}}$$

Substitute numerical values and evaluate the thermal resistance of the aluminum cube:

$$R_{\text{Al}} = \frac{3.00\,\text{cm}}{\left(237\,\dfrac{\text{W}}{\text{m}\cdot\text{K}}\right)(3.00\,\text{cm})^2} = 0.1406\,\text{K/W} = \boxed{0.141\,\text{K/W}}$$

(*b*) Because the cubes are in series, their thermal resistances are additive:

$$R = R_{\text{Cu}} + R_{\text{Al}} = 0.08313\,\text{K/W} + 0.1406\,\text{K/W} = 0.2237\,\text{K/W} = \boxed{0.224\,\text{K/W}}$$

(*c*) Using its definition, find the thermal current:

$$I = \frac{\Delta T}{R} = \frac{100°\text{C} - 20°\text{C}}{0.2237\,\text{K/W}} = 357.6\text{ W} = \boxed{0.36\,\text{kW}}$$

(*d*) Express the temperature at the interface between the two cubes:

$$T_{\text{interface}} = 100°\text{C} - \Delta T_{\text{Cu}}$$

Express the temperature differential across the copper cube:

$$\Delta T_{\text{Cu}} = I_{\text{Cu}} R_{\text{Cu}} = I R_{\text{Cu}}$$

Substitute for ΔT_{Cu} to obtain:

$$T_{\text{interface}} = 100°\text{C} - I R_{\text{Cu}}$$

Substitute numerical values and evaluate $T_{\text{interface}}$:

$$T_{\text{interface}} = 100°\text{C} - (357.6\,\text{W})(0.08313\,\text{K/W}) \approx \boxed{70°\text{C}}$$

37 •• Two metal cubes, one copper and one aluminum, with 3.00-cm-long edges, are arranged in parallel, as shown in Figure 20-18. Find (*a*) the thermal current in each cube, (*b*) the total thermal current, and (*c*) the thermal resistance of the two-cube combination.

Picture the Problem We can use Equation 20-9 to find the thermal current in each cube. Because the currents are additive, we can find the equivalent resistance of the two-cube system from $R_{\text{eq}} = \Delta T / I_{\text{total}}$.

(*a*) The thermal current in each cube is given by Equation 20-9:

$$I = \frac{\Delta T}{R} = kA\frac{\Delta T}{\Delta x}$$

Substitute numerical values and evaluate the thermal current in the copper cube:

$$I_{\text{Cu}} = \left(401\frac{\text{W}}{\text{m}\cdot\text{K}}\right)(3.00\,\text{cm})^2\left(\frac{100°\text{C}-20°\text{C}}{3.00\,\text{cm}}\right) = 962.4\text{ W} = \boxed{0.96\,\text{kW}}$$

Substitute numerical values and evaluate the thermal current in the aluminum cube:

$$I_{\text{Al}} = \left(237\frac{\text{W}}{\text{m}\cdot\text{K}}\right)(3.00\,\text{cm})^2\left(\frac{100°\text{C}-20°\text{C}}{3.00\,\text{cm}}\right) = 568.8\text{ W} = \boxed{0.57\,\text{kW}}$$

(*b*) Because the cubes are in parallel, their total thermal currents are additive:

$$I = I_{\text{Cu}} + I_{\text{Al}} = 962.4\,\text{W} + 568.8\,\text{W}$$
$$= 1.531\,\text{kW} = \boxed{1.5\,\text{kW}}$$

(*c*) Use the relationship between the total thermal current, temperature differential and thermal resistance to find R_{eq}:

$$R_{\text{eq}} = \frac{\Delta T}{I_{\text{total}}} = \frac{100°\text{C}-20°\text{C}}{1.531\,\text{kW}}$$
$$= \boxed{0.052\,\text{K/W}}$$

38 •• The cost of air conditioning a house is approximately proportional to the rate at which heat is absorbed by the house from its surroundings divided by the coefficient of performance (COP) of the air conditioner. Let us denote the temperature difference between the inside temperature and the outside temperature as ΔT. Assuming that the rate at which heat is absorbed by a house is proportional to ΔT and that the air conditioner is operating ideally, show that the cost of air conditioning is proportional to $(\Delta T)^2$ divided by the temperature inside the house.

Picture the Problem The cost of operating the air conditioner is proportional to the energy used in its operation. We can use the definition of the COP to relate the rate at which the air conditioner removes heat from the house to rate at which it must do work to maintain a constant temperature differential between the interior and the exterior of the house. To obtain an expression for the minimum rate at which the air conditioner must do work, we'll assume that it is operating with the maximum efficiency possible. Doing so will allow us to derive an expression for the rate at which energy is used by the air conditioner that we can integrate to obtain the energy (and hence the cost of operation) required.

Relate the cost C of air conditioning the energy W required to operate the air conditioner:

$$C = uW \qquad (1)$$

where u is the unit cost of the energy.

Express the rate dQ/dt at which heat flows into a house provided the house is maintained at a constant temperature:

$$P = \frac{dQ}{dt} = k\Delta T$$

where ΔT is the temperature difference between the interior and exterior of the house.

Use the definition of the COP to relate the rate at which the air conditioner must remove heat dW/dt to maintain a constant temperature:

$$\text{COP} = \frac{dQ/dt}{dW/dt} \Rightarrow \frac{dW}{dt} = \frac{1}{\text{COP}}\frac{dQ}{dt}$$

Express the maximum value of the COP:

$$\text{COP}_{\text{max}} = \frac{T_c}{\Delta T}$$

where $T_c = T_{\substack{\text{inside the}\\ \text{house}}}$ is the temperature of the cold reservoir.

Letting COP = COP_{max}, substitute to obtain an expression for the minimum rate at which the air conditioner must do work in order to maintain a constant temperature:

$$\frac{dW}{dt} = \frac{\frac{dQ}{dt}}{T_c}\Delta T$$

Substituting for dQ/dt gives:

$$\frac{dW}{dt} = \frac{k\Delta T}{T_c}\Delta T = \frac{k}{T_c}(\Delta T)^2$$

Separate variables and integrate this equation to obtain:

$$W = \frac{k}{T_c}(\Delta T)^2\int_0^{\Delta t} dt' = \frac{k}{T_c}(\Delta T)^2\Delta t$$

Substitute in equation (1) to obtain:

$$C = u\frac{k}{T_c}(\Delta T)^2\Delta t \Rightarrow C \propto \boxed{\frac{(\Delta T)^2}{T_c}}$$

39 •• A spherical shell of thermal conductivity k has inside radius r_1 and outside radius r_2 (Figure 20-19). The inside of the shell is held at a temperature T_1, and the outside of the shell is held at temperature T_2, with $T_1 < T_2$. In this problem, you are to show that the thermal current through the shell is given by

$$I = -\frac{4\pi k r_1 r_2}{r_2 - r_1}(T_2 - T_1)$$

where I is positive if heat is transferred in the $+r$ direction. Here is a suggested procedure for obtaining this result: (1) obtain an expression for the thermal current I through a thin spherical shell of radius r and thickness dr when there is a temperature difference dT across the thickness of the shell; (2) explain why the thermal current is the same through each such thin shell; (3) express the thermal current I through such a shell element in terms of the area $A = 4\pi r^2$, the thickness

dr, and the temperature difference *dT* across the element; and (4) separate variables (solve for *dT* in terms of *r* and *dr*) and integrate.

Picture the Problem We can follow the step-by-step instructions given in the problem statement to obtain the differential equation describing the variation of *T* with *r*. Integrating this equation will yield an equation that we can solve for the current *I*.

(1) The thermal current through a thin spherical shell surface of area *A* and thickness *dr* due to a temperature gradient $\frac{dT}{dr}$ is given by:

$$I = kA\frac{dT}{dr}$$

(2) Conservation of energy requires that the thermal current through each shell be the same.

(3) For a shell of area $A = 4\pi r^2$:

$$I = 4\pi kr^2 \frac{dT}{dr}$$

(4) Separating the variables yields:

$$dT = \frac{I}{4\pi k}\frac{dr}{r^2}$$

Integrate from $r = r_1$ to $r = r_2$ and simplify to obtain:

$$\int_{T_1}^{T_2} dT = \frac{I}{4\pi k}\int_{r_1}^{r_2}\frac{dr}{r^2}$$

and

$$T_2 - T_1 = -\frac{I}{4\pi k}\left[\frac{1}{r}\right]_{r_1}^{r_2} = -\frac{I}{4\pi k}\left(\frac{1}{r_1} - \frac{1}{r_2}\right)$$

Solving for *I* gives:

$$I = \boxed{-\frac{4\pi kr_1r_2}{r_2 - r_1}\left(T_2 - T_1\right)}$$

Radiation

40 • Calculate λ_{max} (the wavelength at which the emitted power is maximum) for a human skin. Assume the human skin is a blackbody emitter with a temperature of 33°C.

Picture the Problem We can apply Wein's displacement law to find the wavelength at which the power is a maximum.

Wein's law relates the maximum wavelength of the radiation to the temperature of its source:

$$\lambda_{max} = \frac{2.898\,\text{mm}\cdot\text{K}}{T}$$

Substitute numerical values and evaluate λ_{max}:

$$\lambda_{max} = \frac{2.898\,\text{mm}\cdot\text{K}}{273\,\text{K} + 33\,\text{K}} = \boxed{9.47\,\mu\text{m}}$$

41 • [SSM] The universe is filled with radiation that is believed to be remaining from the Big Bang. If the entire universe is considered to be a blackbody with a temperature equal to 2.3 K, what is the λ_{max} (the wavelength at which the power of the radiation is maximum) of this radiation?

Picture the Problem We can use Wein's law to find the peak wavelength of this radiation.

Wein's law relates the maximum wavelength of the background radiation to the temperature of the universe:

$$\lambda_{max} = \frac{2.898\,\text{mm}\cdot\text{K}}{T}$$

Substituting for T gives:

$$\lambda_{max} = \frac{2.898\,\text{mm}\cdot\text{K}}{2.3\,\text{K}} = \boxed{1.3\,\text{mm}}$$

42 • What is the range of temperatures for star surfaces for which λ_{max} (the wavelength at which the power of the emitted radiation is maximum) is in the visible range?

Picture the Problem The visible portion of the electromagnetic spectrum extends from approximately 400 nm to 700 nm. We can use Wein's law to find the range of temperatures corresponding to these wavelengths.

Wein's law relates the maximum wavelength of the radiation to the temperature of its source:

$$\lambda_{max} = \frac{2.898\,\text{mm}\cdot\text{K}}{T}$$

Solving for T yields:

$$T = \frac{2.898\,\text{mm}\cdot\text{K}}{\lambda_{max}}$$

For λ_{max} = 400 nm:

$$T = \frac{2.898\,\text{mm}\cdot\text{K}}{400\,\text{nm}} = 7250\,\text{K}$$

For λ_{max} = 700 nm:

$$T = \frac{2.898\,\text{mm}\cdot\text{K}}{700\,\text{nm}} = 4140\,\text{K}$$

The range of temperatures is $\boxed{4140\,\text{K} \le \boldsymbol{T} \le 7250\,\text{K}}$.

43 • The heating wires of a 1.00-kW electric heater are red hot at a temperature of 900ºC. Assuming that 100 percent of the heat released is due to radiation and that the wires act as blackbody emitters, what is the effective area of the radiating surface? (Assume a room temperature of 20ºC.)

Picture the Problem We can apply the Stefan-Boltzmann law to find the net power radiated by the wires of its heater to the room.

Relate the net power radiated to the surface area of the heating wires, their temperature, and the room temperature:

$$P_{\text{net}} = e\sigma A\left(T^4 - T_0^4\right) \Rightarrow A = \frac{P_{\text{net}}}{e\sigma\left(T^4 - T_0^4\right)}$$

Substitute numerical values and evaluate A:

$$A = \frac{1.00\,\text{kW}}{(1)\left(5.6703\times10^{-8}\,\dfrac{\text{W}}{\text{m}^2\cdot\text{K}^4}\right)\left[(1173\,\text{K})^4 - (293\,\text{K})^4\right]} = \boxed{93.5\,\text{cm}^2}$$

44 •• A blackened, solid copper sphere that has a radius equal to 4.0 cm hangs in an evacuated enclosure whose walls have a temperature of 20ºC. If the sphere is initially at 0ºC, find the initial rate at which its temperature changes, assuming that heat is transferred by radiation only. (Assume the sphere is a blackbody emitter.)

Picture the Problem The rate at which the copper sphere absorbs radiant energy is given by $dQ/dt = mc\,dT/dt$ and, from the Stephan-Boltzmann law, $P_{\text{net}} = e\sigma A\left(T^4 - T_0^4\right)$ where A is the surface area of the sphere, T_0 is its temperature, and T is the temperature of the walls. We can solve the first equation for dT/dt and substitute P_{net} for dQ/dt in order to find the initial rate at which the temperature of the sphere changes.

Relate the rate at which the sphere absorbs radiant energy to the rate at which its temperature changes:

$$P_{\text{net}} = \frac{dQ}{dt} = mc\frac{dT}{dt}$$

Solving for $\dfrac{dT}{dt}$ and substituting for mc gives:

$$\frac{dT}{dt} = \frac{P_{\text{net}}}{mc} = \frac{P_{\text{net}}}{\rho Vc} = \frac{P_{\text{net}}}{\frac{4}{3}\pi r^3\rho c}$$

Apply the Stefan-Boltzmann law to relate the net power radiated to the sphere to the difference in temperature of the walls and the blackened copper sphere:

$$P_{net} = e\sigma A\left(T^4 - T_0^4\right) = 4\pi r^2 e\sigma\left(T^4 - T_0^4\right)$$

Substitute for P_{net} to obtain:

$$\frac{dT}{dt} = \frac{4\pi r^2 e\sigma\left(T^4 - T_0^4\right)}{\frac{4}{3}\pi r^3 \rho c} = \frac{3e\sigma\left(T^4 - T_0^4\right)}{r\rho c}$$

Substitute numerical values and evaluate dT/dt:

$$\frac{dT}{dt} = -\frac{3(1)\left(5.6703\times10^{-8}\,\frac{\text{W}}{\text{m}^2\cdot\text{K}^4}\right)\left[(293\,\text{K})^4 - (273\,\text{K})^4\right]}{\left(4.0\times10^{-2}\,\text{m}\right)\left(8.93\times10^3\,\frac{\text{kg}}{\text{m}^3}\right)\left(0.386\,\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)} = \boxed{2.2\times10^{-3}\,\text{K/s}}$$

45 •• The surface temperature of the filament of an incandescent lamp is 1300ºC. If the electric power input is doubled, what will the new temperature be? *Hint: Show that you can neglect the temperature of the surroundings.*

Picture the Problem We can apply the Stephan-Boltzmann law to express the net power radiated by the incandescent lamp to its surroundings.

Express the rate at which energy is radiated to the surroundings:

$$P_{net} = e\sigma A\left(T^4 - T_0^4\right) = e\sigma A T^4\left(1 - \left(\frac{T_0}{T}\right)^4\right)$$

Evaluate $\left(\frac{T_0}{T}\right)^4$:

$$\left(\frac{T_0}{T}\right)^4 = \left(\frac{293\,\text{K}}{1573\,\text{K}}\right)^4 \approx 1\times10^{-3}$$

Because $\left(\frac{T_0}{T}\right)^4$ is so small, we can neglect the temperature of the surroundings. Hence:

$$P_{net} \approx e\sigma A T^4 \Rightarrow T = \left(\frac{P_{net}}{e\sigma A}\right)^{1/4}$$

Express the temperature T' when the electric power input is doubled:

$$T' = \left(\frac{2P_{net}}{e\sigma A}\right)^{1/4}$$

Dividing the second of these equations by the first and solving for T gives:

$$\frac{T'}{T} = (2)^{1/4} \Rightarrow T' = (2)^{1/4} T$$

Substitute numerical values and evaluate T'

$$T' = (2)^{1/4}(1573\,\text{K}) = 1871\,\text{K}$$
$$= \boxed{1598°\text{C}}$$

46 •• Liquid helium is stored at its boiling point (4.2 K) in a spherical can that is separated by an evacuated region of space from a surrounding shield that is maintained at the temperature of liquid nitrogen (77 K). If the can is 30 cm in diameter and is blackened on the outside so that it acts as a blackbody emitter, how much helium boils away per hour?

Picture the Problem We can differentiate $Q = mL$, where L is the latent heat of boiling for helium, with respect to time to obtain an expression for the rate at which the helium boils away.

Express the rate at which the helium boils away in terms of the rate at which its container absorbs radiant energy:

$$\frac{dm}{dt} = \frac{P_{\text{net}}}{L} = \frac{e\sigma A\left(T^4 - T_0^4\right)}{L}$$
$$= \frac{e\sigma\pi d^2\left(T^4 - T_0^4\right)}{L}$$
$$= \frac{e\sigma\pi d^2}{L} T^4\left(1 - \left(\frac{T_0}{T}\right)^4\right)$$

If $T_0 << T$, then:

$$\frac{dm}{dt} \approx \frac{e\sigma\pi d^2}{L} T^4$$

Substitute numerical values and evaluate dm/dt:

$$\frac{dm}{dt} \approx \frac{(1)\left(5.6703\times10^{-8}\,\frac{\text{W}}{\text{m}^2\cdot\text{K}^4}\right)\pi(0.30\,\text{m})^2}{21\,\frac{\text{kJ}}{\text{kg}}}(77\,\text{K})^4$$
$$= 2.68\times10^{-5}\,\frac{\text{kg}}{\text{s}} \times \frac{3600\,\text{s}}{\text{h}} = \boxed{97\,\text{g/h}}$$

General Problems

47 • A steel tape is placed around Earth at the equator when the temperature is 0ºC. What will the clearance between the tape and the ground (assumed to be uniform) be if the temperature of the tape increases to 30ºC? Neglect the expansion of Earth.

Picture the Problem The distance by which the tape clears the ground equals the change in the radius of the circle formed by the tape placed around Earth at the equator.

Express the change in the radius of the circle defined by the steel tape:

$\Delta R = R\alpha\Delta T$
where R is the radius of Earth, α is the coefficient of linear expansion of steel, and ΔT is the increase in temperature.

Substitute numerical values and evaluate ΔR:

$$\Delta R = \left(6.37\times10^{6}\ \text{m}\right)\left(11\times10^{-6}\ \text{K}^{-1}\right)\left(30°\text{C}-0°\text{C}\right) = 2.10\times10^{3}\ \text{m} = \boxed{2.1\text{km}}$$

48 •• Show that change in the density ρ of an isotropic material due to an increase in temperature ΔT is given by $\Delta\rho = -\beta\rho\Delta T$.

Picture the Problem We can differentiate the definition of the density of an isotropic material with respect to T and use the definition of the coefficient of volume expansion to express the rate at which the density of the material changes with respect to temperature. Once we have an expression for $d\rho$ in terms of dT, we can apply a differential approximation to obtain $\Delta\rho$ in terms of ΔT.

Using its definition, relate the density of the material to its mass and volume:

$$\rho = \frac{m}{V}$$

Using its definition, relate the volume of the material to its coefficient of volume expansion:

$$\Delta V = \beta V\Delta T$$

Differentiate ρ with respect to T and simplify to obtain:

$$\frac{d\rho}{dT}=\frac{d\rho}{dV}\frac{dV}{dT}=-\frac{m}{V^2}\beta V$$
$$=-\frac{\rho V}{V^2}\beta V=-\rho\beta$$

or

$$d\rho=-\rho\beta dT$$

Using the differential approximations $d\rho \approx \Delta\rho$ and $dT \approx \Delta T$ yields:

$$\Delta\rho=\boxed{-\rho\beta\Delta T}$$

49 •• [SSM] The solar constant is the power received from the Sun per unit area perpendicular to the Sun's rays at the mean distance of Earth from the Sun. Its value at the upper atmosphere of Earth is about 1.37 kW/m^2. Calculate the effective temperature of the Sun if it radiates like a blackbody. (The radius of the Sun is 6.96×10^8 m.).

Picture the Problem We can apply the Stefan-Boltzmann law to express the effective temperature of the Sun in terms of the total power it radiates. We can, in turn, use the intensity of the Sun's radiation in the upper atmosphere of Earth to approximate the total power it radiates.

Apply the Stefan-Boltzmann law to relate the energy radiated by the Sun to its temperature:

$$P_{\rm r}=e\sigma AT^4 \Rightarrow T=\sqrt[4]{\frac{P_{\rm r}}{e\sigma A}}$$

Express the surface area of the sun:

$$A=4\pi R_{\rm S}^2$$

Relate the intensity of the Sun's radiation in the upper atmosphere to the total power radiated by the sun:

$$I=\frac{P_r}{4\pi R^2}\Rightarrow P_r=4\pi R^2 I$$

where R is the Earth-Sun distance.

Substitute for $P_{\rm r}$ and A in the expression for T and simplify to obtain:

$$T=\sqrt[4]{\frac{4\pi R^2 I}{e\sigma 4\pi R_{\rm S}^2}}=\sqrt[4]{\frac{R^2 I}{e\sigma R_{\rm S}^2}}$$

Substitute numerical values and evaluate *T*:

$$T=\sqrt[4]{\frac{\left(1.5\times10^{11}\text{ m}\right)^2\left(1.35\frac{\text{kW}}{\text{m}^2}\right)}{(1)\left(5.67\times10^{-8}\frac{\text{W}}{\text{m}^2\cdot\text{K}}\right)\left(6.96\times10^{8}\text{ m}\right)^2}}=\boxed{5800\text{ K}}$$

50 •• As part of your summer job as an engineering intern at an insulation manufacturer, you are asked to determine the *R* factor of insulating material. This particular material comes in $\frac{1}{2}$-in sheets. Using this material, you construct a hollow cube that has 12-in long edges. You place a thermometer and a 100-W heater inside the box. After thermal equilibrium has been attained, the temperature inside the box is 90ºC when the temperature outside the box is 20ºC. Determine the *R* factor of the material.

Picture the Problem We can solve the thermal-current equation for the *R* factor of the material.

Use the equation for the thermal current to express *I* in terms of the temperature gradient across the insulation:

$$I=kA\frac{\Delta T}{\Delta x}$$

Rewrite this expression in terms of the *R* factor of the material:

$$I=\frac{\Delta T}{\frac{\Delta x}{kA}}=\frac{\Delta T}{\frac{R_f}{A}}=\frac{A\Delta T}{R_f}$$

Solving for the *R* factor gives:

$$R_f=\frac{A\Delta T}{I}=\frac{6A_{\text{one side}}\Delta T}{I}$$

Substitute numerical values and evaluate *R*:

$$R_f=\frac{6\left(12\text{ in}\times\frac{2.54\times10^{-2}\text{ m}}{\text{in}}\right)^2}{100\text{ W}}\left(90°\text{C}-20°\text{C}\right)=\boxed{0.39\frac{\text{K}\cdot\text{m}^2}{\text{W}}}$$

$$=0.390\frac{\text{K}\cdot\text{m}^2}{\frac{\text{J}}{\text{s}}}\times\frac{9\text{ F°}}{5\text{ K}}\times\frac{10.76\text{ ft}^2}{\text{m}^2}\times\frac{1054\text{ J}}{\text{Btu}}\times\frac{1\text{ h}}{3600\text{ s}}=\boxed{2.2\frac{\text{F°}\cdot\text{ft}^2\cdot\text{h}}{\text{Btu}}}$$

51 • (*a*) From the definition of β, the coefficient of volume expansion (at constant pressure), show that $\beta = 1/T$ for an ideal gas. (*b*) The experimentally determined value of β for N_2 gas at 0ºC is 0.003673 K^{-1}. By what percent does this measured value of β differ from the value obtained by modeling N_2 as an ideal gas?

Picture the Problem We can use the definition of the coefficient of volume expansion with the ideal-gas law to show that $\beta = 1/T$.

(*a*) Use the definition of the coefficient of volume expansion to express β in terms of the rate of change of the volume with temperature:

$$\beta = \frac{1}{V}\frac{dV}{dT}$$

For an ideal gas:

$$V = \frac{nRT}{P} \text{ and } \frac{dV}{dT} = \frac{nR}{P}$$

Substitute for $\frac{dV}{dT}$ to obtain:

$$\beta = \frac{1}{V}\frac{nR}{P} = \boxed{\frac{1}{T}}$$

(*b*) Express the percent difference between the experimental value and the theoretical value:

$$\frac{\beta_{\text{exp}} - \beta_{\text{th}}}{\beta_{\text{th}}} = \frac{0.003673\,\text{K}^{-1} - \frac{1}{273}\text{K}^{-1}}{\frac{1}{273}\text{K}^{-1}} < \boxed{0.3\%}$$

52 •• A rod of length L_A, made from material A, is placed next to a rod of length L_B, made of material B. The rods remain in thermal equilibrium with each other. (*a*) Show that even though the lengths of each rod will change with changes in the ambient temperature, the difference between the two lengths will remain constant if the lengths L_A and L_B are chosen such that $L_A/L_B = \alpha_B/\alpha_A$, where α_A and α_B are the coefficients of linear expansion, respectively. (*b*) If material B is steel, material A is brass, and L_A = 250 cm at 0ºC, what is the value of L_B?

Picture the Problem Let ΔL be the difference between L_B and L_A and express L_B and L_A in terms of the coefficients of linear expansion of materials A and B. Requiring that ΔL be constant will lead us to the condition that $L_A/L_B = \alpha_B/\alpha_A$.

(*a*) Express the condition that ΔL does not change when the temperature of the materials changes:

$$\Delta L = L_B - L_A = \text{constant} \qquad (1)$$

Using the definition of the coefficient of linear expansion, substitute for L_B and L_A:

$$\begin{aligned}\Delta L &= (L_B + \alpha_B L_B \Delta T) - (L_A + \alpha_A L_A \Delta T) \\ &= (L_B - L_A) + (\alpha_B L_B - \alpha_A L_A)\Delta T \\ &= \Delta L + (\alpha_B L_B - \alpha_A L_A)\Delta T\end{aligned}$$

or

$$(\alpha_B L_B - \alpha_A L_A)\Delta T = 0$$

The condition that ΔL remain constant when the temperature changes by ΔT is:

$$\alpha_B L_B - \alpha_A L_A = 0$$

Solving for the ratio of L_A to L_B yields:

$$\frac{L_A}{L_B} = \boxed{\frac{\alpha_B}{\alpha_A}}$$

(*b*) From (*a*) we have:

$$L_B = L_{steel} = L_A \frac{\alpha_A}{\alpha_B} = L_{brass} \frac{\alpha_{brass}}{\alpha_{steel}}$$

Substitute numerical values and evaluate L_B:

$$L_B = (250\,\text{cm}) \frac{19 \times 10^{-6}\ \text{K}^{-1}}{11 \times 10^{-6}\ \text{K}^{-1}} = \boxed{430\,\text{cm}}$$

53 •• [SSM] On the average, the temperature of Earth's crust increases 1.0ºC for every increase in depth of 30 m. The average thermal conductivity of Earth's crust material is 0.74 J/m·s·K. What is the heat loss of Earth per second due to conduction from the core? How does this heat loss compare with the average power received from the Sun (which is about 1.37 kW/m^2)?

Picture the Problem We can apply the thermal-current equation to calculate the heat loss of Earth per second due to conduction from its core. We can also use the thermal-current equation to find the power per unit area radiated from Earth and compare this quantity to the solar constant.

Express the heat loss of Earth per unit time as a function of the thermal conductivity of Earth and its temperature gradient:

$$I = \frac{dQ}{dt} = kA\frac{\Delta T}{\Delta x} \qquad (1)$$

or

$$\frac{dQ}{dt} = 4\pi R_E^2 k \frac{\Delta T}{\Delta x}$$

Substitute numerical values and evaluate dQ/dt:

$$\frac{dQ}{dt}=4\pi\left(6.37\times10^{6}\text{ m}\right)^{2}\left(0.74\frac{\text{J}}{\text{m}\cdot\text{s}\cdot\text{K}}\right)\left(\frac{1.0\,\text{C}^\circ}{30\,\text{m}}\right)=\boxed{1.3\times10^{10}\text{ kW}}$$

Rewrite equation (1) to express the thermal current per unit area:

$$\frac{I}{A}=k\frac{\Delta T}{\Delta x}$$

Substitute numerical values and evaluate I/A:

$$\frac{I}{A}=\left(0.74\,\text{J/m}\cdot\text{s}\cdot\text{K}\right)\left(\frac{1.0\,\text{C}^\circ}{30\,\text{m}}\right)$$
$$=0.0247\,\text{W/m}^2$$

Express the ratio of I/A to the solar constant:

$$\frac{I/A}{\text{solar constant}}=\frac{0.0247\,\text{W/m}^2}{1.37\,\text{kW/m}^2}$$
$$<\boxed{0.002\%}$$

54 •• A copper-bottomed saucepan containing 0.800 L of boiling water boils dry in 10.0 min. Assuming that all the heat is transferred through the flat copper bottom, which has a diameter of 15.0 cm and a thickness of 3.00 mm, calculate the temperature of the outside of the copper bottom while some water is still in the pan.

Picture the Problem We can find the temperature of the outside of the copper bottom by finding the temperature difference between the outside of the saucepan and the boiling water. This temperature difference is related to the rate at which the water is evaporating through the thermal-current equation.

Express the temperature outside the pan in terms of the temperature inside the pan:

$$T_{\text{out}}=T_{\text{in}}+\Delta T=100°\text{C}+\Delta T \quad (1)$$

Relate the thermal current through the bottom of the saucepan to its thermal conductivity, area, and the temperature gradient between its surfaces:

$$\frac{\Delta Q}{\Delta t}=kA\frac{\Delta T}{\Delta x}\Rightarrow\Delta T=\frac{1}{kA}\frac{\Delta Q}{\Delta t}\Delta x$$

Because the water is boiling:

$$\Delta Q=mL_{\text{v}}$$

Substitute for ΔQ to obtain:

$$\Delta T=\frac{mL_\text{v}\Delta x}{kA\Delta t}$$

Substituting for ΔT in equation (1) yields:

$$T_\text{out}=100°\text{C}+\frac{mL_\text{v}\Delta x}{kA\Delta t}$$

Substitute numerical values and evaluate T_out:

$$T_\text{out}=100°\text{C}+\frac{(0.800\,\text{kg})\left(2.26\,\frac{\text{MJ}}{\text{kg}}\right)(3.00\times10^{-3}\,\text{m})}{\left(401\,\frac{\text{W}}{\text{m}\cdot\text{K}}\right)\left[\frac{\pi}{4}(0.150\,\text{m})^2\right](600\,\text{s})}=\boxed{101°\text{C}}$$

55 •• A cylindrical steel hot-water tank of cylindrical shape has an inside diameter of 0.550 m and inside height of 1.20 m. The tank is enclosed with a 5.00-cm-thick insulating layer of glass wool whose thermal conductivity is 0.0350 W/(m·K). The insulation is covered by a thin sheet-metal skin. The steel tank and the sheet-metal skin have thermal conductivities that are much greater than that of the glass wool. How much electrical power must be supplied to this tank in order to maintain the water temperature at 75.0ºC when the external temperature is 1.0ºC?

Picture the Problem Thermal energy is lost from this tank through its cylindrical side and its top and bottom. The power required to maintain the temperature of the water in the tank is equal to the rate at which thermal energy is conducted through the insulation.

Express the total thermal current as the sum of the thermal currents through the top and bottom and the side of the hot-water tank:

$$I=I_\text{top and bottom}+I_\text{side} \qquad (1)$$

Express I through the top and bottom surfaces:

$$I_{\substack{\text{top and}\\\text{bottom}}}=2\left(kA\frac{\Delta T}{\Delta x}\right)=\tfrac{1}{2}\pi d^2k\frac{\Delta T}{\Delta x}$$

Substitute numerical values and evaluate $I_{\substack{\text{top and}\\\text{bottom}}}$:

$$I_{\substack{\text{top and}\\\text{bottom}}}=\tfrac{1}{2}\pi(0.550\,\text{m})^2\frac{\left(0.0350\,\frac{\text{W}}{\text{m}\cdot\text{K}}\right)(75.0°\text{C}-1.0°\text{C})}{0.0500\,\text{m}}=24.6\,\text{W}$$

Letting r represent the inside radius of the tank, express the heat current through the cylindrical side:

$$I_{\text{side}} = -kA\frac{dT}{dr} = -2\pi\,kLr\frac{dT}{dr}$$

where the minus sign is a consequence of the heat current being opposite the temperature gradient.

Separating the variables yields:

$$dT = -\frac{I_{\text{side}}}{2\pi\,kL}\frac{dr}{r}$$

Integrate from $r = r_1$ to $r = r_2$ and $T = T_1$ to $T = T_2$ and simplify to obtain:

$$\int_{T_1}^{T_2} dT = -\frac{I_{\text{side}}}{2\pi\,kL}\int_{r_1}^{r_2}\frac{dr}{r}$$

and

$$T_2 - T_1 = -\frac{I_{\text{side}}}{2\pi\,kL}\ln r\Big]_{r_1}^{r_2} = -\frac{I_{\text{side}}}{2\pi\,kL}\ln\left(\frac{r_2}{r_1}\right) = \frac{I_{\text{side}}}{2\pi\,kL}\ln\left(\frac{r_1}{r_2}\right)$$

Solving for I_{side} gives:

$$I_{\text{side}} = \frac{2\pi\,kL}{\ln\left(\dfrac{r_1}{r_2}\right)}\left(T_2 - T_1\right)$$

Substitute numerical values and evaluate I_{side}:

$$I_{\text{side}} = \frac{2\pi\left(0.0350\,\dfrac{\text{W}}{\text{m}\cdot\text{K}}\right)(1.20\,\text{m})}{\ln\left(\dfrac{0.325\,\text{m}}{0.275\,\text{m}}\right)}\left(75.0°\text{C} - 1.0°\text{C}\right) = 117\,\text{W}$$

Substitute numerical values in equation (1) and evaluate I:

$$I = 24.6\,\text{W} + 117\,\text{W} = \boxed{142\,\text{W}}$$

56 ••• The diameter d of a tapered rod of length L is given by $d = d_0(1 + ax)$, where a is a constant and x is the distance from one end. If the thermal conductivity of the material is k what is the thermal resistance of the rod?

Picture the Problem We can use $R = \Delta T/I$ and $I = -kAdT/dt$ to express dT in terms of the linearly increasing diameter of the rod. Integrating this expression will allow us to find ΔT and, hence, R.

The thermal resistance of the rod is given by:

$$R = \frac{\Delta T}{I} \qquad (1)$$

where I the thermal current in the rod.

Relate the thermal current in the rod to its thermal conductivity k, cross-sectional area A, and temperature gradient:

$$I = -kA\frac{dT}{dx}$$

where the minus sign is a consequence of the heat current being opposite the temperature gradient.

Using the dependence of the diameter of the rod on x, express the area of the rod:

$$A = \frac{\pi d^2}{4} = \frac{\pi}{4}d_0^2(1+ax)^2$$

Substitute for A to obtain:

$$I = -k\left[\frac{\pi}{4}d_0^2(1+ax)^2\right]\frac{dT}{dx}$$

Separating variables yields:

$$dT = -\frac{Idx}{k\left[\frac{\pi}{4}d_0^2(1+ax)^2\right]} = -\frac{4I}{\pi k d_0^2}\frac{dx}{(1+ax)^2}$$

Integrating T from T_1 to T_2 and x from 0 to L gives:

$$\int_{T_1}^{T_2} dT = -\frac{4I}{\pi k d_0^2}\int_0^L \frac{dx}{(1+ax)^2}$$

and

$$T_2 - T_1 = \Delta T = \frac{4IL}{\pi k d_0^2(1+aL)}$$

Substitute for ΔT and I in equation (1) and simplify to obtain:

$$R = \frac{\frac{4IL}{\pi k d_0^2(1+aL)}}{I} = \boxed{\frac{4L}{\pi k d_0^2(1+aL)}}$$

57 ••• A solid disk of radius r and mass m is spinning about a frictionless axis through its center and perpendicular to the disk, with angular velocity ω_1 at temperature T_1. The temperature of the disk decreases to T_2. Express the angular velocity ω_2, rotational kinetic energy K_2, and angular momentum L_2 in terms of

their values at the temperature T_1 and the linear expansion coefficient α of the disk.

Picture the Problem Let $\Delta T = T_2 - T_1$. We can apply Newton's second law to establish the relationship between L_2 and L_1 and angular momentum conservation to relate ω_2 and ω_1. We can express both E_2 and E_1 in terms of their angular momenta and rotational inertias and take their ratio to establish their relationship.

Apply $\sum \tau = \frac{\Delta L}{\Delta t}$ to the spinning disk:

Because $\sum \tau = 0$, $\Delta L = 0$ and

$$\boxed{L_2 = L_1}$$

Apply conservation of angular momentum to relate the angular velocity of the disk at T_2 to the angular velocity at T_1:

$$I_2\omega_2 = I_1\omega_1 \Rightarrow \omega_2 = \frac{I_1}{I_2}\omega_1 \qquad (1)$$

Express I_2:

$$I_2 = mr_2^2 = mr_1^2(1+\alpha\Delta T)^2 = I_1\left(1 + 2\alpha\Delta T + (\alpha\Delta T)^2\right)$$

Because $(\alpha\Delta T)^2$ is small compared to $\alpha\Delta T$:

$$I_2 \approx I_1(1 + 2\alpha\Delta T)$$

Substitute for I_2 in equation (1) to obtain:

$$\omega_2 = \frac{I_1}{I_1(1+2\alpha\Delta T)}\omega_1 \qquad (2)$$

Expanding $(1+2\alpha\Delta T)^{-1}$ binomially yields:

$$(1+2\alpha\Delta T)^{-1} = 1 - 2\alpha\Delta T + \text{higher order terms}$$

Because the higher order terms are very small:

$$(1+2\alpha\Delta T)^{-1} \approx 1 - 2\alpha\Delta T$$

Substituting in equation (2) yields:

$$\omega_2 \approx \boxed{(1-2\alpha\Delta T)\omega_1}$$

Express E_2 in terms of L_2 and I_2:

$$E_2 = \frac{L_2^2}{2I_2} = \frac{L_1^2}{2I_2} \text{ because } L_2 = L_1.$$

Express E_1 in terms of L_1 and I_1:

$$E_1 = \frac{L_1^2}{2I_1}$$

Express the ratio of E_2 to E_1 and simplify to obtain:

$$\frac{E_2}{E_1}=\frac{\frac{L_1^2}{2I_2}}{\frac{L_1^2}{2I_1}}=\frac{I_1}{I_2}\Rightarrow E_2=E_1\frac{I_1}{I_2}$$

Substituting for the ratio of I_1 to I_2 yields:

$$E_2=E_1\frac{\omega_2}{\omega_1}=\boxed{E_1(1-2\alpha\Delta T)}$$

58 ••• Write a **spreadsheet** program to graph the average temperature of the surface of Earth as a function of emissivity, using the results of Problem 22. How much does the emissivity have to change in order for the average temperature to increase by 1 K? This result can be thought of as a model for the effect of increasing concentrations of greenhouse gases like methane and CO_2 in Earth's atmosphere.

Picture the Problem The amount of heat radiated by Earth must equal the solar flux from the Sun, or else the temperature on Earth would continually increase. The emissivity of Earth is related to the rate at which it radiates energy into space by the Stefan-Boltzmann law $P_r=e\sigma AT^4$.

Using the Stefan-Boltzmann law, express the rate at which Earth radiates energy as a function of its emissivity e and temperature T:

$$P_r=e\sigma A'T^4$$

where A' is the surface area of Earth.

Use its definition to express the intensity of the radiation P_a absorbed by Earth:

$$I=\frac{P_a}{A}\text{ or }P_a=AI$$

where A is the cross-sectional area of Earth.

For 70% absorption of the Sun's radiation incident on Earth:

$$P_a=(0.70)AI$$

Equate P_r and P_a and simplify:

$$(0.70)AI=e\sigma A'T^4$$

or

$$(0.70)\pi R^2I=e\left(4\pi R^2\sigma T^4\right)$$

Solve for T to obtain:

$$T=\sqrt[4]{\frac{(0.70)I}{4\sigma e}}=Ce^{-1/4} \tag{1}$$

Substitute numerical values for I and σ and simplify to obtain:

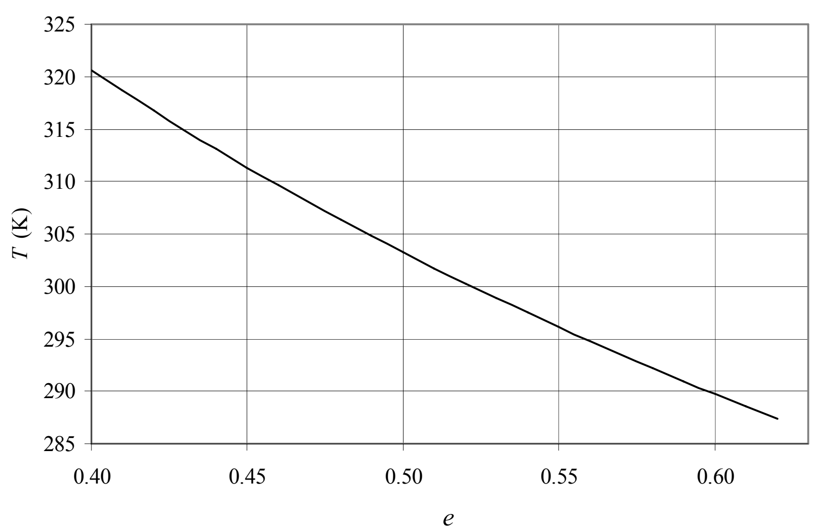
$$T=\sqrt[4]{\frac{(0.70)\left(1370\text{ W/m}^2\right)}{4\left(5.670\times10^{-8}\text{ W/m}^2\cdot\text{K}^4\right)e}}=(255\text{ K})e^{-1/4}$$

A spreadsheet program to evaluate T as a function of e is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B1	255	
B4	0.4	e
B5	B4+0.01	$e + 0.1$
C4	$B$1/(B4^0.25)	$(255\text{K})e^{-1/4}$

	A	B	C	D
1	$T=$	255	K	
2				
3		e	T	
4		0.40	321	
5		0.41	319	
6		0.42	317	
7		0.43	315	
23		0.59	291	
24		0.60	290	
25		0.61	289	
26		0.62	287	

A graph of T as a function of e follows.



Treating e as a variable, differentiate equation (1) to obtain:

$$\frac{dT}{de} = -\frac{1}{4}Ce^{-5/4}de \tag{2}$$

Divide equation (2) by equation (1) to obtain:

$$\frac{dT}{T}=\frac{-\frac{1}{4}Ce^{-5/4}de}{Ce^{-1/4}}=-\frac{1}{4}\frac{de}{e}$$

Use a differential approximation to obtain:

$$\frac{\Delta T}{T}=-\frac{1}{4}\frac{\Delta e}{e}\Rightarrow\frac{\Delta e}{e}=-4\frac{\Delta T}{T}$$

Substitute numerical values ($e\approx 0.615$ for $T_{\text{Earth}}=288$ K) and evaluate $\Delta e/e$:

$$\frac{\Delta e}{e}=-4\left(\frac{1\,\text{K}}{288\,\text{K}}\right)=\boxed{-0.014}$$

or about a 1.4% change.

59 ••• [SSM] A small pond has a layer of ice 1.00 cm thick floating on its surface. (*a*) If the air temperature is –10ºC on a day when there is a breeze, find the rate in centimeters per hour at which ice is added to the bottom of the layer. The density of ice is 0.917 g/cm^3. (*b*) How long do you and your friends have to wait for a 20.0-cm layer to be built up so you can play hockey?

Picture the Problem (*a*) We can differentiate the expression for the heat that must be removed from water in order to form ice to relate *dQ*/*dt* to the rate of ice build-up *dm*/*dt.* We can apply the thermal-current equation to express the rate at which heat is removed from the water to the temperature gradient and solve this equation for *dm*/*dt*. In Part (*b*) we can separate the variables in the differential equation relating *dm*/*dt* and Δ*T* and integrate to find out how long it takes for a 20.0-cm layer of ice to be built up.

(*a*) Relate the heat that must be removed from the water to freeze it to its mass and heat of fusion:

$$Q=mL_{\text{f}}\Rightarrow\frac{dQ}{dt}=L_{\text{f}}\frac{dm}{dt}$$

Using the definition of density, relate the mass of the ice added to the bottom of the layer to its density and volume:

$$m=\rho V=\rho Ax$$

Differentiate with respect to time to express the rate of build-up of the ice:

$$\frac{dm}{dt}=\rho A\frac{dx}{dt}$$

Substitute for $\frac{dm}{dt}$ to obtain:

$$\frac{dQ}{dt}=L_{\text{f}}\rho A\frac{dx}{dt}$$

The thermal-current equation is:

$$\frac{dQ}{dt}=kA\frac{\Delta T}{x}$$

Equate these expressions and solve for $\frac{dx}{dt}$:

$$L_f \rho A \frac{dx}{dt} = kA \frac{\Delta T}{x} \Rightarrow \frac{dx}{dt} = \frac{k}{L_f \rho} \frac{\Delta T}{x} \quad (1)$$

Substitute numerical values and evaluate $\frac{dx}{dt}$:

$$\frac{dx}{dt} = \frac{\left(0.592 \frac{\text{W}}{\text{m} \cdot \text{K}}\right)(0°\text{C} - (-10°\text{C}))}{\left(333.5 \frac{\text{kJ}}{\text{kg}}\right)(917\,\text{kg/m}^3)(0.0100\,\text{m})}$$
$$= 1.94 \frac{\mu\text{m}}{\text{s}} \times \frac{3600\,\text{s}}{\text{h}} = 0.697\,\text{cm/h}$$
$$= \boxed{0.70\,\text{cm/h}}$$

(*b*) Separating the variables in equation (1) gives:

$$x dx = \frac{k \Delta T}{L_f \rho} dt$$

Integrate x from x_i to x_f and t' from 0 to t:

$$\int_{x_i}^{x_f} x dx = \frac{k \Delta T}{L_f \rho} \int_0^t dt'$$

and

$$\tfrac{1}{2}\left(x_f^2 - x_i^2\right) = \frac{k \Delta T}{\rho L_f} t \Rightarrow t = \frac{\rho L_f \left(x_f^2 - x_i^2\right)}{2 k \Delta T}$$

Substitute numerical values and evaluate t:

$$t = \frac{\left(917 \frac{\text{kg}}{\text{m}^3}\right)\left(333.5 \frac{\text{kJ}}{\text{kg}}\right)}{2\left(0.592 \frac{\text{W}}{\text{m} \cdot \text{K}}\right)(0°\text{C} - (-10°\text{C}))}\left[(0.200\,\text{m})^2 - (0.010\,\text{m})^2\right]$$
$$= 1.03 \times 10^6\,\text{s} \times \frac{1\,\text{h}}{3600\,\text{s}} \times \frac{1\,\text{d}}{24\,\text{h}} = \boxed{12\,\text{d}}$$

60 ••• [SSM] A blackened copper cube that has 1.00-cm-long edges is heated to a temperature of 300ºC, and then is placed in a vacuum chamber whose walls are at a temperature of 0ºC. In the vacuum chamber, the cube cools radiatively. (*a*) Show that the (absolute) temperature T of the cube follows the differential equation: $\frac{dT}{dt} = -\frac{e\sigma A}{C}\left(T^4 - T_0^4\right)$ where C is the heat capacity of the cube, A is its surface area, e the emissivity, and T_0 the temperature of the vacuum chamber. (*b*) Using Euler's method (Section 5.4 of Chapter 5), numerically solve the differential equation to find $T(t)$, and graph it. Assume $e = 1.00$. How long does it take the cube to cool to a temperature of 15ºC?

Picture the Problem We can use the Stefan-Boltzmann equation and the definition of heat capacity to obtain the differential equation expressing the rate at which the temperature of the copper block decreases. We can then approximate the differential equation with a difference equation for the purpose of solving for the temperature of the block as a function of time using Euler's method.

(*a*) The rate at which heat is radiated away from the cube is given by:

$$\frac{dQ}{dt} = e\sigma A\left(T^4 - T_0^4\right)$$

Using the definition of heat capacity, relate the thermal current to the rate at which the temperature of the cube is changing:

$$\frac{dQ}{dt} = -C\frac{dT}{dt}$$

Equate these expressions and solve for $\frac{dT}{dt}$ to obtain:

$$\frac{dT}{dt} = \boxed{-\frac{e\sigma A}{C}\left(T^4 - T_0^4\right)}$$

Approximating the differential equation by the difference equation gives:

$$\frac{\Delta T}{\Delta t} = -\frac{e\sigma A}{C}\left(T^4 - T_0^4\right)$$

Solving for ΔT yields:

$$\Delta T = -\frac{e\sigma A}{C}\left(T^4 - T_0^4\right)\Delta t$$

or

$$T_{n+1} = T_n - \frac{e\sigma A}{C}\left(T_n^4 - T_0^4\right)\Delta t \qquad (1)$$

Use the definition of heat capacity to obtain:

$$C = mc = \rho Vc$$

Substitute numerical values (see Figure 13-1 for ρ_{Cu} and Table 19-1 for c_{Cu}) and evaluate C:

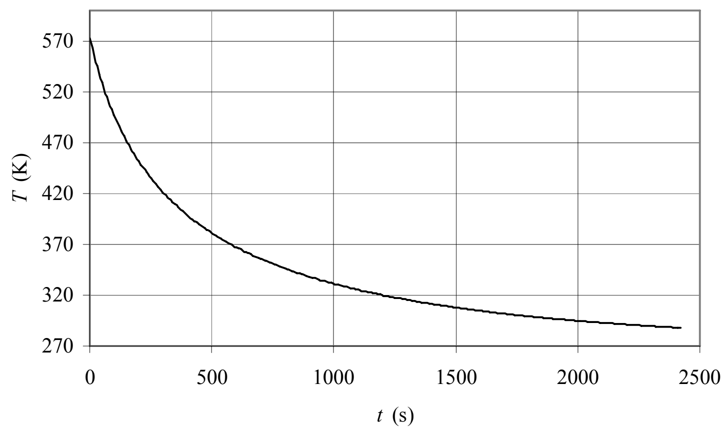
$$C = \left(8.93\times10^3\ \frac{\mathrm{kg}}{\mathrm{m}^3}\right)\left(1.00\times10^{-6}\ \mathrm{m}^3\right)\left(0.386\frac{\mathrm{kJ}}{\mathrm{kg\cdot K}}\right) = 3.45\frac{\mathrm{J}}{\mathrm{K}}$$

(b) A spreadsheet program to calculate T as a function of t using equation (1) is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B1	5.67E−08	σ
B2	6.00E−04	A
B3	3.45	C
B4	273	T_0
B5	10	Δt
A9	A8+$B$5	$t+\Delta t$
B9	B8-($B$1*$B$2/$B$3) *(B8^4−$B$4^4)*$B$5	$T_n - \frac{e\sigma A}{C}\left(T_n^4 - T_0^4\right)\Delta t$

	A	B	C
1	$\sigma=$	5.67×10^{-8}	$W/m^2 \cdot K^4$
2	$A=$	6.00×10^{-4}	m^2
3	$C=$	3.45	J/K
4	$T_0=$	273	K
5	$\Delta t=$	10	s
6			
7	t (s)	T (K)	
8	0	573.00	
9	10	562.92	
10	20	553.56	
11	30	544.85	
248	2400	288.22	
249	2410	288.08	
250	2420	287.95	
251	2430	287.82	

From the spreadsheet solution, the time to cool to 15°C (288 K) is about 2420 s or $\boxed{40.5\,\text{min}.}$ A graph of T as a function of t follows.



Chapter 21
The Electric Field 1: Discrete Charge Distributions

Conceptual Problems

1 • Objects are composed of atoms which are composed of charged particles (protons and electrons); however, we rarely observe the effects of the electrostatic force. Explain why we do not observe these effects.

Determine the Concept The net charge on large objects is always very close to zero. Hence the most obvious force is the gravitational force.

2 • A carbon atom can become a carbon *ion* if it has one or more of its electrons removed during a process called *ionization*. What is the net charge on a carbon atom that has had two of its electrons removed? (*a*) +*e*, (*b*) – *e*, (*c*) +2*e*, (*d*) –2*e*

Determine the Concept If two electrons are removed from a carbon atom, it will have a net positive charge of +2*e*. $\boxed{(c)}$ is correct.

3 •• You do a simple demonstration for your high school physics teacher in which you claim to disprove Coulomb's law. You first run a rubber comb through your dry hair, then use it to attract tiny neutral pieces of paper on the desk. You then say ″Coulomb's law states that for there to be electrostatic forces of attraction between two objects, both objects need to be charged. However, the paper was not charged. So according to Coulomb's law, there should be no electrostatic forces of attraction between them, yet there clearly was.″ You rest your case. (*a*) What is wrong with your assumptions? (*b*) Does attraction between the paper and the comb require that the net charge on the comb be negative? Explain.

Determine the Concept
(*a*) Coulomb's law is only valid for point particles. The paper bits cannot be modeled as point particles because the paper bits become polarized.

(*b*) No, the attraction does not depend on the sign of the charge on the comb. The induced charge on the paper that is closest to the comb is always opposite in sign to the charge on the comb, and thus the net force on the paper is always attractive.

4 •• You have a positively charged insulating rod and two metal spheres on insulating stands. Give step-by-step directions of how the rod, without actually touching either sphere, can be used to give one of the spheres (*a*) a negative charge, and (*b*) a positive charge.

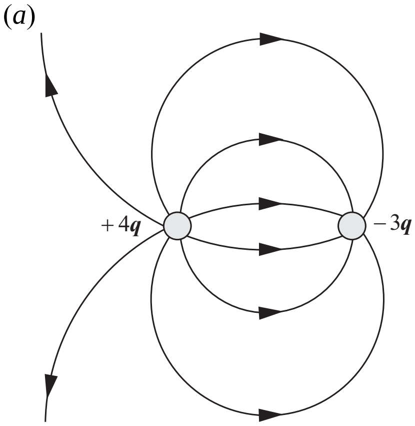
Determine the Concept
(*a*) Connect the metal sphere to ground; bring the insulating rod near the metal sphere and disconnect the sphere from ground; then remove the insulating rod. The sphere will be negatively charged.

(*b*) Bring the insulating rod in contact with the metal sphere; some of the positive charge on the rod will be transferred to the metal sphere.

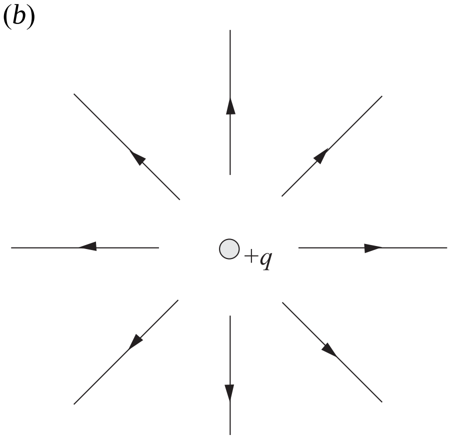
5 •• (*a*) Two point particles that have charges of $+4q$ and $-3q$ are separated by distance d. Use field lines to draw a visualization of the electric field in the neighborhood of this system. (*b*) Draw the field lines at distances much greater than d from the charges.

Determine the Concept (*a*) We can use the rules for drawing electric field lines to draw the electric field lines for this system. Two field lines have been assigned to each charge q. (*b*) At distances much greater than the separation distance between the two charges, the system of two charged bodies will ″look like″ a single charge of $+q$ and the field pattern will be that due to a point charge of $+q$. Eight field lines have been assigned to the single charge.

(*a*)



(*b*)



6 •• A metal sphere is positively charged. Is it possible for the sphere to electrically attract another positively charged ball? Explain your answer.

Comment: DAVID: The ISM solution to 10 needs to be fleshed out.

Determine the Concept Yes. Because a metal sphere is a conductor, the proximity of a positively charged ball (not necessarily a conductor), will induce a redistribution of charges on the metal sphere with the surface nearer the positively charged ball becoming negatively charged. Because the negative charges on the metal sphere are closer to the positively charged ball than are the positive charges on the metal sphere, the net force will be attractive.

7 •• A simple demonstration of electrostatic attraction can be done simply by dangling a small ball of crumpled aluminum foil on a string and bringing a charged rod near the ball. The ball initially will be attracted to the rod, but once they touch, the ball will be strongly repelled from it. Explain these observations.

Determine the Concept Assume that the rod has a negative charge. When the charged rod is brought near the aluminum foil, it induces a redistribution of charges with the side nearer the rod becoming positively charged, and so the ball of foil swings toward the rod. When it touches the rod, some of the negative charge is transferred to the foil, which, as a result, acquires a net negative charge and is now repelled by the rod.

8 •• Two positive point charges that are equal in magnitude are fixed in place, one at $x = 0.00$ m and the other at $x = 1.00$ m, on the x axis. A third positive point charge is placed at an equilibrium position. (*a*) Where is this equilibrium position? (*b*) Is the equilibrium position stable if the third particle is constrained to move parallel with the x axis? (*c*) What about if it is constrained to move parallel with the y axis? Explain.

Determine the Concept
(*a*) A third positive charge can be placed midway between the fixed positive charges. This is the only location.

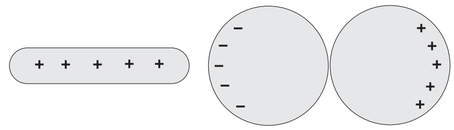
(*b*) Yes. The position identified in (*a*) is one of stable equilibrium. It is stable in the x direction because, regardless of whether you displace the third positive charge to the right or to the left, the net force acting on it is back toward the midpoint between the two fixed charges.

(*c*) If the third positive charge is displaced in the y direction, the net force acting on it will be away from its equilibrium position. Hence, the position midway between the fixed positive charges is one of unstable equilibrium in the y direction.

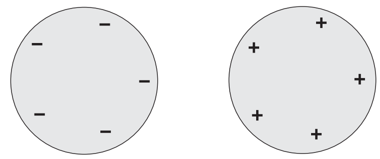
9 •• Two neutral conducting spheres are in contact and are supported on a large wooden table by insulated stands. A positively charged rod is brought up close to the surface of one of the spheres on the side opposite its point of contact with the other sphere. (*a*) Describe the induced charges on the two conducting spheres, and sketch the charge distributions on them. (*b*) The two spheres are separated and then the charged rod is removed. The spheres are then separated far apart. Sketch the charge distributions on the separated spheres.

Determine the Concept Because the spheres are conductors, there are free electrons on them that will reposition themselves when the positively charged rod is brought nearby.

(*a*) On the sphere near the positively charged rod, the induced charge is negative and near the rod. On the other sphere, the net charge is positive and on the side far from the rod. This is shown in the diagram.

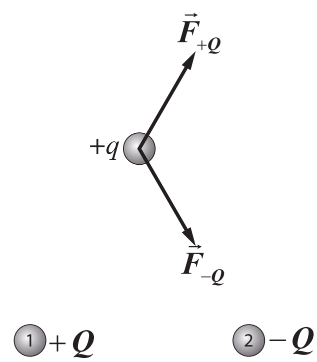


(*b*) When the spheres are separated and far apart and the rod has been removed, the induced charges are distributed uniformly over each sphere. The charge distributions are shown in the diagram.



10 •• Three point charges, $+q$, $+Q$, and $-Q$, are placed at the corners of an equilateral triangle as shown in Figure 21-33. No other charged objects are nearby. (*a*) What is the direction of the net force on charge $+q$ due to the other two charges? (*b*) What is the total electric force on the system of three charges? Explain.

Determine the Concept The forces acting on point charge $+q$ are shown in the diagram. The force acting on point charge $+q$ due to point charge $-Q$ is along the line joining them and directed toward $-Q$. The force acting on point charge $+q$ due to point charge $+Q$ is along the line joining them and directed away from point charge $+Q$.



(*a*) Because point charges $+Q$ and $-Q$ are equal in magnitude, the forces due to these charges are equal and their sum (the net force on charge $+q$) will be $\boxed{\text{to the right.}}$ Note that the vertical components of these forces add up to zero.

(*b*) Because no other charged objects are nearby, the forces acting on this system of three point charges are internal forces and the net force acting on the system is $\boxed{\text{zero}}$.

11 •• A positively charged particle is free to move in a region with an electric field $\vec{E}$. Which statements must be true?

(*a*) The particle is accelerating in the direction perpendicular to $\vec{E}$.

(*b*) The particle is accelerating in the direction of $\vec{E}$.
(*c*) The particle is moving in the direction of $\vec{E}$.
(*d*) The particle could be momentarily at rest.
(*e*) The force on the particle is opposite the direction of $\vec{E}$.
(*f*) The particle is moving opposite the direction of $\vec{E}$.

Determine the Concept
(*a*) False. The only force acting on the particle is in the direction of $\vec{E}$.

(*b*) True. The electrical force experienced by the particle is, by definition, in the direction of $\vec{E}$.

(*c*) False. We don't know whether the particle is moving or momentarily at rest. All we know is that the net force acting on it is in the direction of $\vec{E}$.

(*d*) Possibly, Whether the particle is ever at rest depends on how it was initially placed in the electric field. That is, it depends on whether its initial velocity was zero, in the direction of $\vec{E}$, or opposite $\vec{E}$. We do know that, if it is at any time at rest, it will not stay at rest.

(*e*) False. By definition, the electric force acting on a positively charged particle in an electric field is in the direction of the field.

(*f*) False. All we know for sure is that the electric force and, hence, the acceleration of the particle, is in the direction of $\vec{E}$. The particle could be moving in the direction of the field, in the direction opposite the field, or it could be momentarily at rest.

12 •• Four charges are fixed in place at the corners of a square as shown in Figure 21-34. No other charges are nearby. Which of the following statements is true?

(*a*) $\vec{E}$ is zero at the midpoints of all four sides of the square.
(*b*) $\vec{E}$ is zero at the center of the square.
(*c*) $\vec{E}$ is zero midway between the top two charges and midway between the bottom two charges.

Determine the Concept $\vec{E}$ is zero wherever the net force acting on a test charge is zero.

(*a*) False. A test charge placed at these locations will experience a net force.

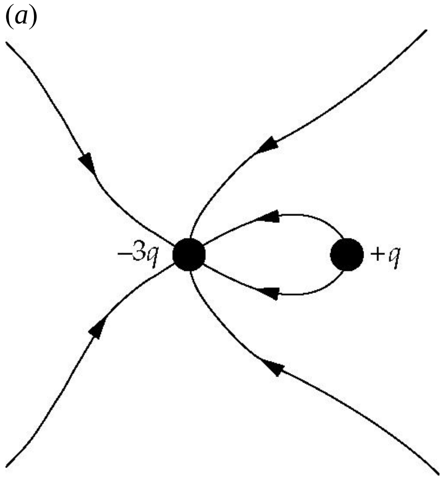
(*b*) True. At the center of the square the two positive charges alone produce a net electric field of zero, and the two negative charges alone also produce a net electric field of zero. Thus, the net force acting on a test charge at the midpoint of the square is zero.

(*c*) False. A test charge placed at either of these locations will experience a net force.

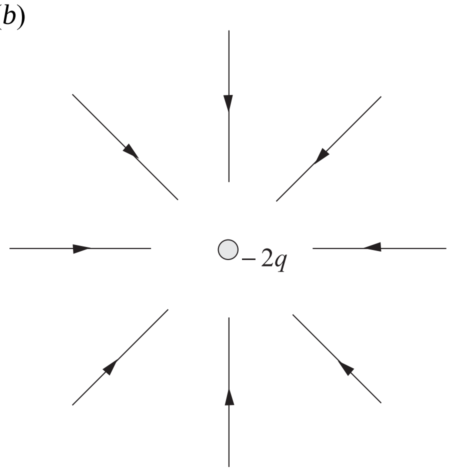
13 •• **[SSM]** Two point particles that have charges of $+q$ and $-3q$ are separated by distance d. (*a*) Use field lines to sketch the electric field in the neighborhood of this system. (*b*) Draw the field lines at distances much greater than d from the charges.

Determine the Concept (*a*) We can use the rules for drawing electric field lines to draw the electric field lines for this system. In the field-line sketch we've assigned 2 field lines to each charge q. (*b*) At distances much greater than the separation distance between the two charges, the system of two charged bodies will ″look like″ a single charge of $-2q$ and the field pattern will be that due to a point charge of $-2q$. Four field lines have been assigned to each charge $-q$.

(*a*)

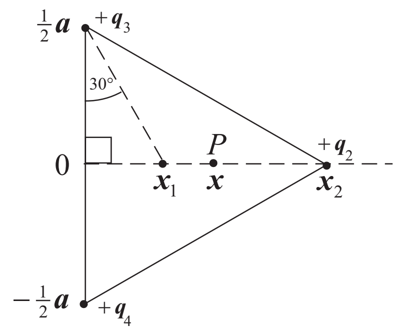


(*b*)



14 •• Three equal positive point charges (each charge $+q$) are fixed at the vertices of an equilateral triangle with sides of length a. The origin is at the midpoint of one side the triangle, the center of the triangle on the x axis at $x = x_1$ and the vertex opposite the origin is on the x axis at $x = x_2$. (*a*) Express x_1 and x_2 in terms of a. (*b*) Write an expression for the electric field on the x axis a distance x from the origin on the interval $0 \le x < x_2$. (*c*) Show that the expression you obtained in (*b*) gives the expected results for $x = 0$ and for $x = x_1$.

Picture the Problem (*a*) We can use the geometry of an equilateral triangle to express x_1 and x_2 in terms of the side a of the triangle. (*b*) The electric field on the x axis a distance x from the origin on the interval $0 \le x < x_2$ is the superposition of the electric fields due to the point charges q_2, q_3, and q_4 located at the vertices of the triangle.



(*a*) Apply the Pythagorean theorem to the triangle whose vertices are at $(0,0), (0,\frac{1}{2}a)$, and $(\boldsymbol{x}_2,0)$ to obtain:

$$x_2^2 + \left(\tfrac{1}{2}a\right)^2 = a^2 \Rightarrow x_2 = \boxed{\tfrac{\sqrt{3}}{2}a}$$

Referring to the triangle whose vertices are at $(0,0), (0,\frac{1}{2}a)$, and $(\boldsymbol{x}_1,0)$, note that:

$$\tan 30° = \frac{x_1}{\frac{1}{2}a} \Rightarrow x_1 = \tfrac{1}{2}a\tan 30°$$

Substitute for $\tan 30°$ and evaluate x_1:

$$x_1 = \boxed{\tfrac{\sqrt{3}}{6}a}$$

(*b*) The electric field at P is the superposition of the electric fields due to the charges q_2, q_3, and q_4:

$$\vec{\boldsymbol{E}}_P = \vec{\boldsymbol{E}}_2 + \vec{\boldsymbol{E}}_3 + \vec{\boldsymbol{E}}_4 \qquad (1)$$

Express the electric field at P due to q_2:

$$\vec{\boldsymbol{E}}_2 = \frac{kq_2}{r_{2,P}^2}\hat{\boldsymbol{r}}_{2,P} = \frac{kq_2}{r_{2,P}^3}\hat{\boldsymbol{r}}_{2,P}$$

where

$$\hat{\boldsymbol{r}}_{2,P} = (x - x_2)\hat{\boldsymbol{i}} = \left(x - \tfrac{\sqrt{3}}{2}a\right)\hat{\boldsymbol{i}}$$

and

$$r_{2,P} = x_2 - x$$

Substituting for q_2, $\vec{\boldsymbol{r}}_{2,P}$, and $r_{2,P}$ yields:

$$\vec{\boldsymbol{E}}_2 = \frac{kq}{\left(\frac{\sqrt{3}}{2}a - x\right)^3}\left(x - \tfrac{\sqrt{3}}{2}a\right)\hat{\boldsymbol{i}} = -\frac{kq}{\left(\frac{\sqrt{3}}{2}a - x\right)^2}\hat{\boldsymbol{i}}$$

Express the electric field at P due to q_3:

$$\vec{E}_3 = \frac{kq_3}{r_{3,P}^2}\vec{r}_{3,P} = \frac{kq_3}{r_{3,P}^3}\vec{r}_{3,P}$$

where

$$\vec{r}_{3,P} = (x-0)\hat{i} + \left(0-\tfrac{1}{2}a\right)\hat{j} = x\hat{i} - \tfrac{1}{2}a\hat{j}$$

and

$$r_{3,P} = \sqrt{(x-0)^2 + \left(0-\tfrac{1}{2}a\right)^2} = \sqrt{x^2 + \tfrac{1}{4}a^2}$$

Substituting for q_3, $\vec{r}_{3,P}$, and $r_{3,P}$ yields:

$$\vec{E}_3 = \frac{kq}{\left(x^2 + \frac{1}{4}a^2\right)^{3/2}}\left(x\hat{i} - \tfrac{1}{2}a\hat{j}\right)$$

Proceed similarly for $\vec{E}_4$ to obtain:

$$\vec{E}_4 = \frac{kq}{\left(x^2 + \frac{1}{4}a^2\right)^{3/2}}\left(x\hat{i} + \tfrac{1}{2}a\hat{j}\right)$$

Substituting for $\vec{E}_2, \vec{E}_3$, and $\vec{E}_4$ in equation (1) and simplifying yields:

$$\vec{E}_P = -\frac{kq}{\left(\frac{\sqrt{3}}{2}a - x\right)^2}\hat{i} + \frac{kq}{\left(x^2 + \frac{1}{4}a^2\right)^{3/2}}\left(x\hat{i} - \tfrac{1}{2}a\hat{j}\right) + \frac{kq}{\left(x^2 + \frac{1}{4}a^2\right)^{3/2}}\left(x\hat{i} + \tfrac{1}{2}a\hat{j}\right)$$

$$= \boxed{kq\left[-\frac{1}{\left(\frac{\sqrt{3}}{2}a - x\right)^2} + \frac{2x}{\left(x^2 + \frac{1}{4}a^2\right)^{3/2}}\right]\hat{i}}$$

(*c*) Evaluating $\vec{E}_P(0)$ yields:

$$\vec{E}_P(0) = kq\left[-\frac{1}{\left(\frac{\sqrt{3}}{2}a\right)^2} + \frac{2(0)}{\left(\frac{1}{4}a^2\right)^{3/2}}\right]\hat{i} = \boxed{-\frac{kq}{\left(\frac{\sqrt{3}}{2}a\right)^2}\hat{i}}$$

Note that, because the electric fields due to q_3 and q_4 cancel each other at the origin and the resultant field is that due to q_2, this is the expected result.

Evaluate $\vec{E}_P\left(\frac{\sqrt{3}}{6}a\right)$ to obtain:

$$\vec{E}_P\left(\tfrac{\sqrt{3}}{6}a\right) = kq\left[-\frac{1}{\left(\frac{\sqrt{3}}{2}a - \frac{\sqrt{3}}{6}a\right)^2} + \frac{2\left(\frac{\sqrt{3}}{6}a\right)}{\left(\left(\frac{\sqrt{3}}{6}a\right)^2 + \frac{1}{4}a^2\right)^{3/2}}\right]\hat{i} = kq\left[-\frac{3}{a^2} + \frac{3}{a^2}\right]\hat{i} = \boxed{0}$$

Note that, because the point at the center of the equilateral triangle is equidistant from the three vertices, the electric fields due to the charges at the vertices cancel and this is the expected result.

15 •• A molecule has a dipole moment given by $\vec{p}$. The molecule is momentarily at rest with $\vec{p}$ making an angle θ with a uniform electric field $\vec{E}$. Describe the subsequent motion of the dipole moment.

Comment: DAVID: The ISM solution to 23 is lacking. The first sentence in the solution is irrelevant. The second is close to being irrelevant. You need to show how at least one of these is done. I would avoid the field lines and just use Coulombs law qualitatively.

Determine the Concept The dipole moment rotates back and forth in oscillatory motion. The dipole moment gains angular speed as it rotates toward the direction of the electric field, and loses angular speed as it rotates away from the direction of the electric field.

16 •• True or false:

(*a*) The electric field of a point charge always points away from the charge.
(*b*) The electric force on a charged particle in an electric field is always in the same direction as the field.
(*c*) Electric field lines never intersect.
(*d*) All molecules have dipole moments in the presence of an external electric field.

(*a*) False. The direction of the field is toward a negative charge.

(*b*) False. The direction of the electric force acting on a point charge depends on the sign of the point charge.

(*c*) False. Electric field lines intersect any point in space occupied by a point charge.

(*d*) True. An electric field partially polarizes the molecules; resulting in the separation of their charges and the creation of electric dipole moments.

17 ••• **[SSM]** Two molecules have dipole moments of equal magnitude. The dipole moments are oriented in various configurations as shown in Figure 21-35. Determine the electric-field direction at each of the numbered locations. Explain your answers.

Comment:

Determine the Concept Figure 21-23 shows the electric field due to a single dipole, where the dipole moment is directed toward the right. The electric field due two a pair of dipoles can be obtained by superposing the two electric fields.

	1	2	3
(*a*)	down	up	up
(*b*)	up	right	left
(*c*)	down	up	up
(*d*)	down	up	up

Estimation and Approximation

18 •• Estimate the force required to bind the two protons in the He nucleus together. HINT: Model the protons as point charges. *You will need to have an estimate of the distance between them.*

Picture the Problem Because the nucleus is in equilibrium, the binding force must be equal to the electrostatic force of repulsion between the protons.

Apply $\sum \vec{F} = 0$ to a proton to obtain: $F_{\text{binding}} - F_{\text{electrostatic}} = 0$

Using Coulomb's law, substitute for $F_{\text{electrostatic}}$: $\frac{kq^2}{r^2} - F_{\text{electrostatic}} = 0 \Rightarrow F_{\text{binding}} = \frac{kq^2}{r^2}$

Assuming the diameter of the He nucleus to be approximately 10^{-15} m, substitute numerical values and evaluate $F_{\text{electrostatic}}$:

$$F_{\text{binding}} = \frac{(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.602\times10^{-19}\ \text{C})^2}{(10^{-15}\ \text{m})^2} \approx \boxed{0.2\ \text{kN}}$$

19 •• A popular classroom demonstration consists of rubbing a plastic rod with fur to give the rod charge, and then placing the rod near an empty soda can that is on its side (Figure 21-36). Explain why the can will roll toward the rod.

Comment: DAVID: I am sure the answer to 27 is correct. I think the can is grounded, so it becomes charged, not polarized.

Determine the Concept Because the can is grounded, the presence of the negatively charged plastic rod induces a positive charge on it. The positive charges induced on the can are attracted, via the Coulomb interaction, to the negative charges on the plastic rod. Unlike charges attract, so the can will roll toward the rod.

20 ••• Sparks in air occur when ions in the air are accelerated to a such a high speed by an electric field that when they impact on neutral gas molecules the neutral molecules become ions. If the electric field strength is large enough, the ionized collision products are themselves accelerated and produce more ions on impact, and so forth. This avalanche of ions is what we call a spark. (*a*) Assume that an ion moves, on average, exactly one mean free path through the air before hitting a molecule. If the ion needs to acquire approximately 1.0 eV of kinetic energy in order to ionize a molecule, estimate the minimum strength of the electric field required at standard room pressure and temperature. Assume that the cross-sectional area of an air molecule is about 0.10 nm^2. (*b*) How does the strength of the electric field in (*a*) depend on temperature? (*c*) How does the strength of the electric field in (*a*) depend on pressure?

Picture the Problem We can use the definition of electric field to express E in terms of the work done on the ionizing electrons and the distance they travel λ between collisions. We can use the ideal-gas law to relate the number density of molecules in the gas ρ and the scattering cross-section σ to the mean free path and, hence, to the electric field.

(*a*) Apply conservation of energy to relate the work done on the electrons by the electric field to the change in their kinetic energy:

$$W = \Delta K = F\Delta s$$

From the definition of electric field we have:

$$F = qE$$

Substitute for F and Δs to obtain:

$W = qE\lambda$, where the mean free path λ is the distance traveled by the electrons between ionizing collisions with nitrogen atoms.

The mean free path λ of a particle is related to the scattering cross-section σ and the number density for air molecules n:

$$\lambda = \frac{1}{\sigma n}$$

Substitute for λ to obtain:

$$W = \frac{qE}{\sigma n} \Rightarrow E = \frac{\sigma nW}{q}$$

Use the ideal-gas law to obtain:

$$n = \frac{N}{V} = \frac{P}{kT}$$

Substituting for n yields:

$$E = \frac{\sigma PW}{qkT} \qquad (1)$$

Substitute numerical values and evaluate E:

$$E = \frac{\left(0.10\,\text{nm}^2\right)\left(101.325\times10^3\,\frac{\text{N}}{\text{m}^2}\right)\left(1.0\,\text{eV}\right)\left(1.602\times10^{-19}\,\frac{\text{J}}{\text{eV}}\right)}{\left(1.602\times10^{-19}\,\text{C}\right)\left(1.381\times10^{-23}\,\frac{\text{J}}{\text{K}}\right)\left(300\,\text{K}\right)} \approx \boxed{2.4\times10^6\ \text{N/C}}$$

(*b*) From equation (1) we see that:

$$\boxed{E \propto T^{-1}}$$

(*c*) Also, from equation (1):

$$\boxed{E \propto P}$$

Charge

21 • A plastic rod is rubbed against a wool shirt, thereby acquiring a charge of –0.80 μC. How many electrons are transferred from the wool shirt to the plastic rod?

Picture the Problem The charge acquired by the plastic rod is an integral number of electronic charges, that is, $q = n_e(-e)$.

Relate the charge acquired by the plastic rod to the number of electrons transferred from the wool shirt:

$$q = n_e(-e) \Rightarrow n_e = \frac{q}{-e}$$

Substitute numerical values and evaluate n_e:

$$n_e = \frac{-0.80\ \mu\text{C}}{-1.602\times10^{-19}\ \dfrac{\text{C}}{\text{electron}}} = \boxed{5.0\times10^{12}\ \text{electrons}}$$

22 • A charge equal to the charge of Avogadro's number of protons ($N_A = 6.02 \times 10^{23}$) is called a *faraday*. Calculate the number of coulombs in a faraday.

Picture the Problem One faraday = N_Ae. We can use this definition to find the number of coulombs in a faraday.

Use the definition of a faraday to calculate the number of coulombs in a faraday:

$$1\ \text{faraday} = N_A e = (6.02\times10^{23}\ \text{electrons})(1.602\times10^{-19}\ \text{C/electron}) = \boxed{9.63\times10^{4}\ \text{C}}$$

23 • **[SSM]** What is the total charge of all of the protons in 1.00 kg of carbon?

Picture the Problem We can find the number of coulombs of positive charge there are in 1.00 kg of carbon from $Q = 6n_Ce$, where n_C is the number of atoms in 1.00 kg of carbon and the factor of 6 is present to account for the presence of 6 protons in each atom. We can find the number of atoms in 1.00 kg of carbon by setting up a proportion relating Avogadro's number, the mass of carbon, and the molecular mass of carbon to n_C. See Appendix C for the molar mass of carbon.

Express the positive charge in terms of the electronic charge, the number of protons per atom, and the number of atoms in 1.00 kg of carbon:

$$Q = 6n_{\text{C}}e$$

Using a proportion, relate the number of atoms in 1.00 kg of carbon n_{C}, to Avogadro's number and the molecular mass M of carbon:

$$\frac{n_{\text{C}}}{N_{\text{A}}} = \frac{m_{\text{C}}}{M} \Rightarrow n_{\text{C}} = \frac{N_{\text{A}}m_{\text{C}}}{M}$$

Substitute for n_{C} to obtain:

$$Q = \frac{6N_{\text{A}}m_{\text{C}}e}{M}$$

Substitute numerical values and evaluate Q:

$$Q = \frac{6\left(6.022\times10^{23}\,\frac{\text{atoms}}{\text{mol}}\right)(1.00\,\text{kg})\left(1.602\times10^{-19}\,\text{C}\right)}{0.01201\frac{\text{kg}}{\text{mol}}} = \boxed{4.82\times10^{7}\,\text{C}}$$

24 •• Suppose a cube of aluminum which is 1.00 cm on a side accumulates a net charge of +2.50 pC. (*a*)What percentage of the electrons originally in the cube was removed? (*b*) By what percentage has the mass of the cube decreased because of this removal?

Picture the Problem (*a*) The percentage of the electrons originally in the cube that was removed can be found from the ratio of the number of electrons removed to the number of electrons originally in the cube. (*b*) The percentage decrease in the mass of the cube can be found from the ratio of the mass of the electrons removed to the mass of the cube.

(*a*) Express the ratio of the electrons removed to the number of electrons originally in the cube:

$$\frac{N_{\text{rem}}}{N_{\text{ini}}} = \frac{\dfrac{Q_{\text{accumulated}}}{e}}{N_{\substack{\text{electrons}\\\text{per atom}}}N_{\text{atoms}}} \qquad (1)$$

The number of atoms in the cube is the ratio of the mass of the cube to the mass of an aluminum atom:

$$N_{\text{atoms}} = \frac{m_{\text{cube}}}{m_{\text{Al atom}}} = \frac{\rho_{\text{Al}}V_{\text{cube}}}{m_{\text{Al atom}}}$$

The mass of an aluminum atom is its molar mass divided by Avogadro's number:

$$m_{\text{Al atom}} = \frac{M_{\text{Al}}}{N_{\text{A}}}$$

Substituting and simplifying yields:

$$N_{\text{atoms}} = \frac{\rho_{\text{Al}} V_{\text{cube}}}{\frac{M_{\text{Al}}}{N_{\text{A}}}} = \frac{\rho_{\text{Al}} V_{\text{cube}} N_{\text{A}}}{M_{\text{Al}}}$$

Substitute for N_{atoms} in equation (1) and simplify to obtain:

$$\frac{N_{\text{rem}}}{N_{\text{ini}}} = \frac{\frac{Q_{\text{accumulated}}}{e}}{N_{\substack{\text{electrons}\\ \text{per atom}}} \left(\frac{\rho_{\text{Al}} V_{\text{cube}} N_{\text{A}}}{M_{\text{Al}}} \right)} = \frac{Q_{\text{accumulated}} M_{\text{Al}}}{N_{\substack{\text{electrons}\\ \text{per atom}}} \rho_{\text{Al}} V_{\text{cube}} e N_{\text{A}}}$$

Substitute numerical values and evaluate $\frac{N_{\text{rem}}}{N_{\text{ini}}}$:

$$\frac{N_{\text{rem}}}{N_{\text{ini}}} = \frac{(2.50\ \text{pC})\left(26.98\ \frac{\text{g}}{\text{mol}}\right)}{\left(13\frac{\text{electrons}}{\text{atom}}\right)\left(2.70\frac{\text{g}}{\text{cm}^3}\right)(1.00\ \text{cm})^3\left(1.602\times10^{-19}\ \text{C}\right)\left(6.022\times10^{23}\ \frac{\text{atoms}}{\text{mol}}\right)} \approx \boxed{1.99\times10^{-15}\ \%}$$

(*b*) Express the ratio of the mass of the electrons removed to the mass of the cube:

$$\frac{m_{\text{rem}}}{m_{\text{cube}}} = \frac{N_{\text{rem}} m_{\text{electron}}}{\rho_{\text{Al}} V_{\text{cube}}}$$

From (*a*), the number of electrons removed is given by:

$$N_{\text{rem}} = \frac{Q_{\text{accumulated}}}{e}$$

Substituting and simplifying yields:

$$\frac{m_{\text{rem}}}{m_{\text{cube}}} = \frac{\frac{Q_{\text{accumulated}}}{e} m_{\text{electron}}}{\rho_{\text{Al}} V_{\text{cube}}} = \frac{Q_{\text{accumulated}} m_{\text{electron}}}{e \rho_{\text{Al}} V_{\text{cube}}}$$

Substitute numerical values and evaluate $\frac{m_{\text{rem}}}{m_{\text{cube}}}$:

$$\frac{m_{\text{rem}}}{m_{\text{cube}}} = \frac{(2.50\ \text{pC})\left(9.109\times10^{-31}\ \text{kg}\right)}{\left(1.602\times10^{-19}\ \text{C}\right)\left(2.70\frac{\text{g}}{\text{cm}^3}\right)\left(1.00\ \text{cm}^3\right)} \approx \boxed{5.26\times10^{-19}\ \%}$$

25 •• During a process described by the *photoelectric effect*, ultra-violet light can be used to charge a piece of metal. (*a*) If such light is incident on a slab of conducting material and electrons are ejected with enough energy that they escape the surface of the metal, how long before the metal has a net charge of +1.50 nC if 1.00×10^6 electrons are ejected per second? (*b*) If 1.3 eV is needed to eject an electron from the surface, what is the power rating of the light beam? (Assume this process is 100% efficient.)

Picture the Problem (*a*) The required time is the ratio of the charge that accumulates to the rate at which it is delivered to the conductor. (*b*) We can use the definition of power to find the power rating of the light beam.

(*a*) The required time is the ratio of the charge that accumulates to the rate at which it is delivered:

$$\Delta t = \frac{\Delta q}{I} = \frac{\Delta q}{dq/dt}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{1.50\,\text{nC}}{\left(1.00\times10^{6}\,\dfrac{\text{electrons}}{\text{s}}\right)\left(1.602\times10^{-19}\,\dfrac{\text{C}}{\text{electron}}\right)} = 9.363\times10^{3}\times\frac{1\,\text{h}}{3600\,\text{s}} = \boxed{2.60\,\text{h}}$$

(*b*) The power rating of the light beam is the rate at which it delivers energy:

$$P = \frac{\Delta E}{\Delta t}$$

The energy delivered by the beam is the product of the energy per electron, the electron current (that is, the number of electrons removed per unit time), and the elapsed time:

$$\Delta E = E_{\substack{\text{per}\\\text{electron}}} I_{\text{electron}} \Delta t$$

Substituting for ΔE in the expression for P and simplifying yields:

$$P = \frac{E_{\substack{\text{per}\\\text{electron}}} I_{\text{electron}} \Delta t}{\Delta t} = E_{\substack{\text{per}\\\text{electron}}} I_{\text{electron}}$$

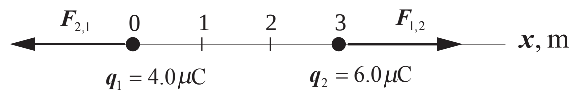
Substitute numerical values and evaluate *P*:

$$P = \left(1.3\,\frac{\text{eV}}{\text{electron}}\times\frac{1.602\times10^{-19}\,\text{J}}{\text{eV}}\right)\left(1.00\times10^{6}\,\frac{\text{electrons}}{\text{s}}\right) = \boxed{2.1\times10^{-13}\,\text{W}}$$

Coulomb's Law

26 • A point charge $q_1 = 4.0\ \mu C$ is at the origin and a point charge $q_2 = 6.0\ \mu C$ is on the x-axis at $x = 3.0$ m. (*a*) Find the electric force on charge q_2. (*b*) Find the electric force on q_1. (*c*) How would your answers for Parts (*a*) and (*b*) differ if q_2 were $-6.0\ \mu C$?

Picture the Problem We can find the electric forces the two charges exert on each by applying Coulomb's law and Newton's 3rd law. Note that $\hat{\boldsymbol{r}}_{1,2} = \hat{\boldsymbol{i}}$ because the vector pointing from q_1 to q_2 is in the positive x direction. The diagram shows the situation for Parts (*a*) and (*b*).



(*a*) Use Coulomb's law to express the force that q_1 exerts on q_2:

$$\vec{F}_{1,2} = \frac{kq_1q_2}{r_{1,2}^2}\hat{\boldsymbol{r}}_{1,2}$$

Substitute numerical values and evaluate $\vec{F}_{1,2}$:

$$\vec{F}_{1,2} = \frac{\left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)(4.0\,\mu\text{C})(6.0\,\mu\text{C})}{(3.0\,\text{m})^2}\hat{\boldsymbol{i}} = \boxed{(24\,\text{mN})\hat{\boldsymbol{i}}}$$

(*b*) Because these are action-and-reaction forces, we can apply Newton's 3rd law to obtain:

$$\vec{F}_{2,1} = -\vec{F}_{1,2} = \boxed{-(24\,\text{mN})\hat{\boldsymbol{i}}}$$

(*c*) If q_2 is $-6.0\ \mu C$, the force between q_1 and q_2 is attractive and both force vectors are reversed:

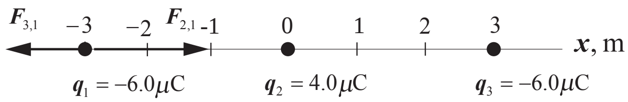
$$\vec{F}_{1,2} = \frac{\left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)(4.0\,\mu\text{C})(-6.0\,\mu\text{C})}{(3.0\,\text{m})^2}\hat{\boldsymbol{i}} = \boxed{-(24\,\text{mN})\hat{\boldsymbol{i}}}$$

and

$$\vec{F}_{2,1} = -\vec{F}_{1,2} = \boxed{(24\,\text{mN})\hat{\boldsymbol{i}}}$$

27 • **[SSM]** Three point charges are on the x-axis: $q_1 = -6.0\ \mu C$ is at $x = -3.0$ m, $q_2 = 4.0\ \mu C$ is at the origin, and $q_3 = -6.0\ \mu C$ is at $x = 3.0$ m. Find the electric force on q_1.

Picture the Problem q_2 exerts an attractive electric force $\vec{F}_{2,1}$ on point charge q_1 and q_3 exerts a repulsive electric force $\vec{F}_{3,1}$ on point charge q_1. We can find the net electric force on q_1 by adding these forces (that is, by using the superposition principle).



Express the net force acting on q_1:

$$\vec{F}_1 = \vec{F}_{2,1} + \vec{F}_{3,1}$$

Express the force that q_2 exerts on q_1:

$$\vec{F}_{2,1} = \frac{k|q_1||q_2|}{r_{2,1}^2}\hat{\boldsymbol{i}}$$

Express the force that q_3 exerts on q_1:

$$\vec{F}_{3,1} = \frac{k|q_1||q_3|}{r_{3,1}^2}\left(-\hat{\boldsymbol{i}}\right)$$

Substitute and simplify to obtain:

$$\vec{F}_1 = \frac{k|q_1||q_2|}{r_{2,1}^2}\hat{\boldsymbol{i}} - \frac{k|q_1||q_3|}{r_{3,1}^2}\hat{\boldsymbol{i}}$$
$$= k|q_1|\left(\frac{|q_2|}{r_{2,1}^2} - \frac{|q_3|}{r_{3,1}^2}\right)\hat{\boldsymbol{i}}$$

Substitute numerical values and evaluate $\vec{F}_1$:

$$\vec{F}_1 = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(6.0\,\mu\text{C})\left(\frac{4.0\,\mu\text{C}}{(3.0\,\text{m})^2} - \frac{6.0\,\mu\text{C}}{(6.0\,\text{m})^2}\right)\hat{\boldsymbol{i}} = \boxed{\left(1.5\times10^{-2}\ \text{N}\right)\hat{\boldsymbol{i}}}$$

28 •• A 2.0 μC point charge and a 4.0 μC point charge are a distance L apart. Where should a third point charge be placed so that the electric force on that third charge is zero?

Comment: DAVID: Note the changes in 36 nd 37.

Picture the Problem The third point charge should be placed at the location at which the forces on the third point charge due to each of the other two point charges cancel. There can be no such place except on the line between the two point charges. Denote the 2.0 μC and 4.0 μC point charges by the numerals 2 and 4, respectively, and the third point charge by the numeral 3. Assume that the 2.0 μC point charge is to the left of the 4.0 μC point charge, let the $+x$ direction be to the right. Then the 4.0 μC point charge is located at $x = L$.

Apply the condition for translational equilibrium to the third point charge:

$$\vec{F}_{4,3} + \vec{F}_{2,3} = 0$$

or

$$F_{4,3} = F_{2,3} \qquad (1)$$

Letting the distance from the third point charge to the 4.0 μC point charge be x, express the force that the 4.0 μC point charge exerts on the third point charge:

$$F_{4,3} = \frac{kq_3q_4}{(L-x)^2}$$

The force that the 2.0 μC point charge exerts on the third charge is given by:

$$F_{2,3} = \frac{kq_3q_2}{x^2}$$

Substitute in equation (1) to obtain:

$$\frac{kq_3q_4}{(L-x)^2} = \frac{kq_3q_2}{x^2}$$

or, simplifying,

$$\frac{q_4}{(L-x)^2} = \frac{q_2}{x^2}$$

Substituting $q_4 = 2q_2$ and rewriting this equation explicitly as a quadratic equations yields:

$$x^2 + 2Lx - L^2 = 0$$

Use the quadratic formula to obtain:

$$x = \frac{-2L \pm \sqrt{4L^2 + 4L^2}}{2} = -L \pm \sqrt{2}L$$

The root corresponding to the negative sign between the terms is extraneous because it corresponds to a position to the left of the 2.0 μC point charge and is, therefore, not a physically meaningful root. Hence the third point charge should be placed between the point charges and a distance equal to $0.41L$ away from the 2.0-μC charge.

29 •• A –2.0 μC point charge and a 4.0 μC point charge are a distance L apart. Where should a third point charge be placed so that the electric force on that third charge is zero?

Picture the Problem The third point charge should be placed at the location at which the forces on the third point charge due to each of the other two point charges cancel. There can be no such place between the two point charges. Beyond the 4.0 μC point charge, and on the line containing the two point charges, the force due to the 4.0 μC point charge overwhelms the force due to the –2.0 μC point charge. Beyond the –2.0 μC point charge, and on the line containing the two

point charges, however, we can find a place where these forces cancel because they are equal in magnitude and oppositely directed. Denote the –2.0 μC and 4.0 μC point charges by the numerals 2 and 4, respectively, and the third point charge by the numeral 3. Let the +x direction be to the right with the origin at the position of the –2.0 μC point charge and the 4.0 μC point charge be located at $x = L$.

Apply the condition for translational equilibrium to the third point charge:

$$\vec{F}_{4,3} + \vec{F}_{2,3} = 0$$

or

$$F_{4,3} = F_{2,3} \qquad (1)$$

Letting the distance from the third point charge to the 2.0 μC point charge be x, express the force that the 4.0 μC point charge exerts on the third point charge:

$$F_{4,3} = \frac{kq_3q_4}{(L+x)^2}$$

The force that the –2.0 μC point charge exerts on the third point charge is given by:

$$F_{2,3} = \frac{kq_3q_2}{x^2}$$

Substitute for $F_{4,3}$ and $F_{2,3}$ in equation (1) to obtain:

$$\frac{kq_3q_4}{(L+x)^2} = \frac{kq_3q_2}{x^2} \Rightarrow \frac{q_4}{(L+x)^2} = \frac{q_2}{x^2}$$

Substituting $q_4 = 2q_2$ and rewriting this equation explicitly as a quadratic equations yields:

$$x^2 - 2Lx - L^2 = 0$$

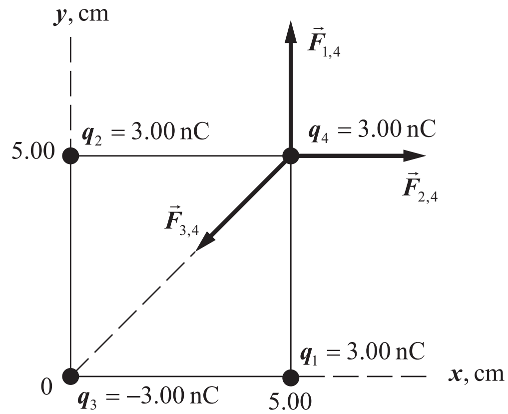
Use the quadratic formula to obtain:

$$x = \frac{2L \pm \sqrt{4L^2 + 4L^2}}{2} = L \pm \sqrt{2}L$$

The root corresponding to the positive sign between the terms is extraneous because it corresponds to a position to the right of the 2.0 μC point charge and is, therefore, not a physically meaningful root. Hence the third point charge should be placed a distance equal to 0.41L from the –2.0-μC charge on the side away from the 4.0-μC charge.

30 •• Three point charges, each of magnitude 3.00 nC, are at separate corners of a square of edge length 5.00 cm. The two point charges at opposite corners are positive, and the third point charge is negative. Find the electric force exerted by these point charges on a fourth point charge q_4 = +3.00 nC at the remaining corner.

Picture the Problem The configuration of the point charges and the forces on the fourth point charge are shown in the figure … as is a coordinate system. From the figure it is evident that the net force on the point charge q_4 is along the diagonal of the square and directed away from point charge q_3. We can apply Coulomb's law to express $\vec{F}_{1,4}$, $\vec{F}_{2,4}$ and $\vec{F}_{3,4}$ and then add them (that is, use the principle of superposition of forces) to find the net electric force on point charge q_4.



Express the net force acting on point charge q_4:

$$\vec{F}_4 = \vec{F}_{1,4} + \vec{F}_{2,4} + \vec{F}_{3,4} \quad (1)$$

Express the force that point charge q_1 exerts on point charge q_4:

$$\vec{F}_{1,4} = \frac{kq_1q_4}{r_{1,4}^2}\hat{j}$$

Substitute numerical values and evaluate $\vec{F}_{1,4}$:

$$\vec{F}_{1,4} = \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(3.00\,\text{nC})\left(\frac{3.00\,\text{nC}}{(0.0500\,\text{m})^2}\right)\hat{j} = \left(3.236\times10^{-5}\,\text{N}\right)\hat{j}$$

Express the force that point charge q_2 exerts on point charge q_4:

$$\vec{F}_{2,4} = \frac{kq_2q_4}{r_{2,4}^2}\hat{i}$$

Substitute numerical values and evaluate $\vec{F}_{2,4}$:

$$\vec{F}_{2,4} = \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(3.00\,\text{nC})\left(\frac{3.00\,\text{nC}}{(0.0500\,\text{m})^2}\right)\hat{i} = \left(3.236\times10^{-5}\,\text{N}\right)\hat{i}$$

Express the force that point charge q_3 exerts on point charge q_4:

$$\vec{F}_{3,4} = \frac{kq_3q_4}{r_{3,4}^2}\hat{r}_{3,4}$$, where $\hat{r}_{3,4}$ is a unit vector pointing from q_3 to q_4.

Express $\vec{r}_{3,4}$ in terms of $\vec{r}_{3,1}$ and $\vec{r}_{1,4}$:

$$\begin{aligned}\vec{r}_{3,4} &= \vec{r}_{3,1} + \vec{r}_{1,4}\\ &= (0.0500\,\text{m})\hat{i} + (0.0500\,\text{m})\hat{j}\end{aligned}$$

Convert $\vec{r}_{3,4}$ to $\hat{r}_{3,4}$:

$$\hat{r}_{3,4} = \frac{\vec{r}_{3,4}}{|\vec{r}_{3,4}|} = \frac{(0.0500\,\text{m})\hat{i} + (0.0500\,\text{m})\hat{j}}{\sqrt{(0.0500\,\text{m})^2 + (0.0500\,\text{m})^2}} = 0.707\,\hat{i} + 0.707\,\hat{j}$$

Substitute numerical values and evaluate $\vec{F}_{3,4}$:

$$\begin{aligned}\vec{F}_{3,4} &= \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(-3.00\,\text{nC})\left(\frac{3.00\,\text{nC}}{\left(0.0500\sqrt{2}\,\text{m}\right)^2}\right)\left(0.707\,\hat{i} + 0.707\,\hat{j}\right)\\ &= -\left(1.14\times10^{-5}\,\text{N}\right)\hat{i} - \left(1.14\times10^{-5}\,\text{N}\right)\hat{j}\end{aligned}$$

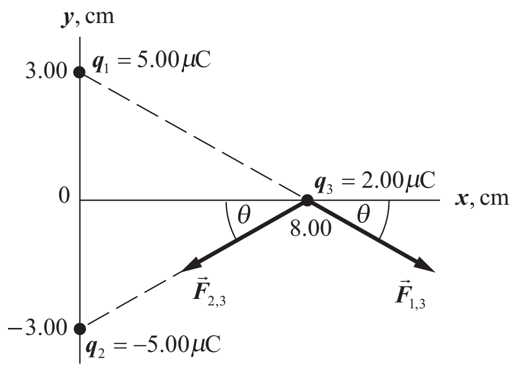
Substitute numerical values in equation (1) and simplify to find $\vec{F}_4$:

$$\begin{aligned}\vec{F}_4 &= \left(3.24\times10^{-5}\,\text{N}\right)\hat{j} + \left(3.24\times10^{-5}\,\text{N}\right)\hat{i} - \left(1.14\times10^{-5}\,\text{N}\right)\hat{i} - \left(1.14\times10^{-5}\,\text{N}\right)\hat{j}\\ &= \boxed{\left(2.10\times10^{-5}\,\text{N}\right)\hat{i} + \left(2.10\times10^{-5}\,\text{N}\right)\hat{j}}\end{aligned}$$

This result tells us that the net force is 2.97×10^{-5} N along the diagonal in the direction away from the −3.0 nC charge.

31 •• A point charge of 5.00 μC is on the y axis at y = 3.00 cm, and a second point charge of –5.00 μC is on the y axis at y = –3.00 cm. Find the electric force on a point charge of 2.00 μC on the x axis at x = 8.00 cm.

Picture the Problem The configuration of the point charges and the forces on point charge q_3 are shown in the figure … as is a coordinate system. From the geometry of the charge distribution it is evident that the net force on the 2.00 μC point charge is in the negative y direction. We can apply Coulomb's law to express $\vec{F}_{1,3}$ and $\vec{F}_{2,3}$ and then add them (that is, use the principle of superposition of forces) to find the net force on point charge q_3.



The net force acting on point charge q_3 is given by:

$$\vec{F}_3 = \vec{F}_{1,3} + \vec{F}_{2,3}$$

The force that point charge q_1 exerts on point charge q_3 is:

$$\vec{F}_{1,3} = F\cos\theta\,\hat{i} - F\sin\theta\,\hat{j}$$

F is given by:

$$F = \frac{kq_1q_3}{r^2} = \frac{\left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(5.00\ \mu\text{C})(2.00\ \mu\text{C})}{(0.0300\ \text{m})^2 + (0.0800\ \text{m})^2} = 12.32\ \text{N}$$

and

$$\theta = \tan^{-1}\left(\frac{3.00\ \text{cm}}{8.00\ \text{cm}}\right) = 20.56°$$

The force that point charge q_2 exerts on point charge q_3 is:

$$\vec{F}_{2,3} = -F\cos\theta\,\hat{i} - F\sin\theta\,\hat{j}$$

Substitute for $\vec{F}_{1,3}$ and $\vec{F}_{2,3}$ and simplify to obtain:

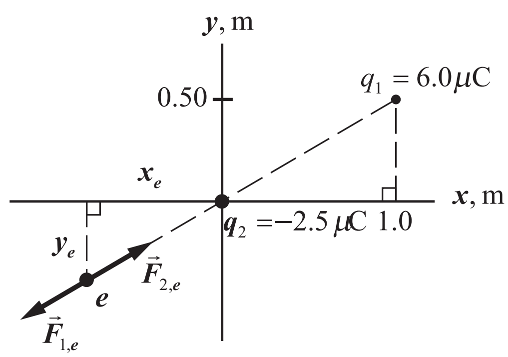
$$\begin{aligned}\vec{F}_3 &= F\cos\theta\,\hat{i} - F\sin\theta\,\hat{j} - F\cos\theta\,\hat{i} \\ &\quad - F\sin\theta\,\hat{j} \\ &= -2F\sin\theta\,\hat{j}\end{aligned}$$

Substitute numerical values and evaluate $\vec{F}_3$:

$$\begin{aligned}\vec{F}_3 &= -2(12.32\ \text{N})\sin 20.56°\,\hat{j} \\ &= \boxed{-(8.65\ \text{N})\hat{j}}\end{aligned}$$

32 •• A point particle that has a charge of –2.5 μC is located at the origin. A second point particle that has a charge of 6.0 μC is at x = 1.0 m, y = 0.50 m. A third point particle, and electron, is at a point with coordinates (x, y). Find the values of x and y such that the electron is in equilibrium.

Picture the Problem The positions of the point particles are shown in the diagram. It is apparent that the electron must be located along the line joining the two point particles. Moreover, because it is negatively charged, it must be closer to the particle with a charge of –2.5 μC than to the particle with a charge of 6.0 μC, as is indicated in the figure. We can find the x and y coordinates of the electron's position by equating the two electrostatic forces acting on it and solving for its distance from the origin. We can use similar triangles to express this radial distance in terms of the x and y coordinates of the electron.



Express the condition that must be satisfied if the electron is to be in equilibrium:

$$F_{1,e} = F_{2,e}$$

Letting r represent the distance from the origin to the electron, express the magnitude of the force that the particle whose charge is q_1 exerts on the electron:

$$F_{1,e} = \frac{kq_1e}{\left(r + \sqrt{1.25\,\text{m}}\right)^2}$$

Express the magnitude of the force that the particle whose charge is q_2 exerts on the electron:

$$F_{2,e} = \frac{k|q_2|e}{r^2}$$

Substitute and simplify to obtain:

$$\frac{q_1}{\left(r + \sqrt{1.25\,\text{m}}\right)^2} = \frac{|q_2|}{r^2}$$

Substitute for q_1 and q_2 and simplify to obtain:

$$\frac{6}{\left(r+\sqrt{1.25\,\text{m}}\right)^2}=\frac{2.5}{r^2}$$

Solving for r yields:

$r = 2.036\,\text{m}$

and

$r = -0.4386\,\text{m}$

Because $r < 0$ is unphysical, we'll consider only the positive root.

Use the similar triangles in the diagram to establish the proportion involving the y coordinate of the electron:

$$\frac{y_e}{0.50\,\text{m}}=\frac{2.036\,\text{m}}{1.12\,\text{m}} \Rightarrow y_e = 0.909\ \text{m}$$

Use the similar triangles in the diagram to establish the proportion involving the x coordinate of the electron:

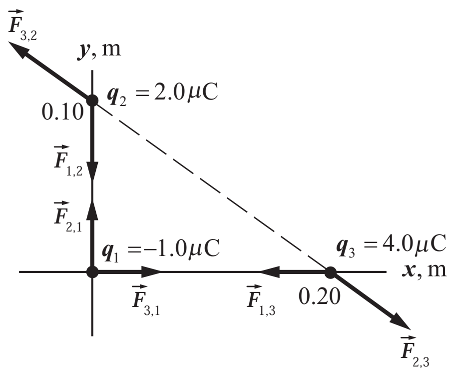
$$\frac{x_e}{1.0\ \text{m}}=\frac{2.036\,\text{m}}{1.12\,\text{m}} \Rightarrow x_e = 1.82\ \text{m}$$

The coordinates of the electron's position are:

$$(x_e, y_e) = \boxed{(-1.8\,\text{m}, -0.91\,\text{m})}$$

33 •• A point particle that has a charge of –1.0 μC is located at the origin; a second point particle that has a charge of 2.0 μC is located at $x = 0$, $y = 0.10$ m; and a third point particle that has a charge of 4.0 μC is located at $x = 0.20$ m, $y = 0$. Find the total electric force on each of the three point charges.

Picture the Problem Let q_1 represent the charge of the point particle at the origin, q_2 the charge of the point particle at (0, 0.10 m), and q_3 the charge of the point particle at (0.20 m, 0). The following diagram shows the forces acting on each of the point particles. Note the action-and-reaction pairs. We can apply Coulomb's law and the principle of superposition of forces to find the net force acting on each of the point particles.



Express the net force acting on the point particle whose charge is q_1:

$$\vec{F}_1 = \vec{F}_{2,1} + \vec{F}_{3,1}$$

Express the force that the point particle whose charge is q_2 exerts on the point particle whose charge is q_1:

$$\vec{F}_{2,1} = \frac{kq_2q_1}{r_{2,1}^2}\hat{r}_{2,1} = \frac{kq_2q_1}{r_{2,1}^2}\frac{\vec{r}_{2,1}}{r_{2,1}} = \frac{kq_2q_1}{r_{2,1}^3}\vec{r}_{2,1}$$

Substitute numerical values and evaluate $\vec{F}_{2,1}$:

$$\vec{F}_{2,1} = \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(2.0\,\mu\text{C})\frac{(-1.0\,\mu\text{C})}{(0.10\,\text{m})^3}(-0.10\,\text{m})\hat{j} = (1.80\,\text{N})\hat{j}$$

Express the force that the point particle whose charge is q_3 exerts on the point particle whose charge is q_1:

$$\vec{F}_{3,1} = \frac{kq_3q_1}{r_{3,1}^3}\vec{r}_{3,1}$$

Substitute numerical values and evaluate $\vec{F}_{3,1}$:

$$\vec{F}_{3,1} = \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(4.0\,\mu\text{C})\frac{(-1.0\,\mu\text{C})}{(0.20\,\text{m})^3}(-0.20\,\text{m})\hat{i} = (0.899\,\text{N})\hat{i}$$

Substitute to find $\vec{F}_1$:

$$\vec{F}_1 = \boxed{(0.90\,\text{N})\hat{i} + (1.8\,\text{N})\hat{j}}$$

Express the net force acting on the point particle whose charge is q_2:

$$\vec{F}_2 = \vec{F}_{3,2} + \vec{F}_{1,2} = \vec{F}_{3,2} - \vec{F}_{2,1} = \vec{F}_{3,2} - (1.80\,\text{N})\hat{j}$$

because $\vec{F}_{1,2}$ and $\vec{F}_{2,1}$ are action-and-reaction forces.

Express the force that the point particle whose charge is q_3 exerts on the point particle whose charge is q_2:

$$\vec{F}_{3,2} = \frac{kq_3q_2}{r_{3,2}^3}\vec{r}_{3,2} = \frac{kq_3q_2}{r_{3,2}^3}\left[(-0.20\,\text{m})\hat{i} + (0.10\,\text{m})\hat{j}\right]$$

Substitute numerical values and evaluate $\vec{F}_{3,2}$:

$$\vec{F}_{3,2} = \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(4.0\,\mu\text{C})\frac{(2.0\,\mu\text{C})}{(0.224\,\text{m})^3}\left[(-0.20\,\text{m})\hat{i} + (0.10\,\text{m})\hat{j}\right]$$
$$= (-1.28\,\text{N})\hat{i} + (0.640\,\text{N})\hat{j}$$

Find the net force acting on the point particle whose charge is q_2:

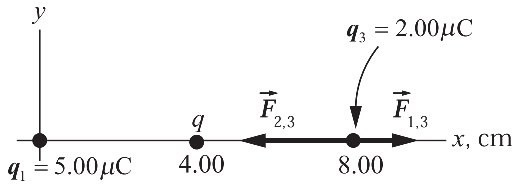
$$\vec{F}_2 = \vec{F}_{3,2} - (1.80\,\text{N})\hat{j} = (-1.28\,\text{N})\hat{i} + (0.640\,\text{N})\hat{j} - (1.80\,\text{N})\hat{j}$$
$$= \boxed{(-1.3\,\text{N})\hat{i} - (1.2\,\text{N})\hat{j}}$$

Noting that $\vec{F}_{1,3}$ and $\vec{F}_{3,1}$ are an action-and-reaction pair, as are $\vec{F}_{2,3}$ and $\vec{F}_{3,2}$, express the net force acting on the point particle whose charge is q_3:

$$\vec{F}_3 = \vec{F}_{1,3} + \vec{F}_{2,3} = -\vec{F}_{3,1} - \vec{F}_{3,2} = -(0.899\,\text{N})\hat{i} - \left[(-1.28\,\text{N})\hat{i} + (0.640\,\text{N})\hat{j}\right]$$
$$= \boxed{(0.4\,\text{N})\hat{i} - (0.64\,\text{N})\hat{j}}$$

34 •• A point particle that has a charge of 5.00 μC is located at $x = 0$, $y = 0$ and a point particle that has a charge q is located at $x = 4.00$ cm, $y = 0$. The electric force on a point particle that has a charge of 2.00 μC at $x = 8.00$ cm, $y = 0$ is $-(19.7\text{ N})\hat{i}$. When this 2.00-μC charge is repositioned at $x = 17.8$ cm, $y = 0$, the electric force on it is zero. Determine the charge q.

Picture the Problem Let q_1 represent the charge of the point particle at the origin and q_3 the charge of the point particle initially at (8.00 cm, 0) and later positioned at (17.8 cm, 0). The diagram shows the forces acting on the point particle whose charge is q_3 at (8.00 cm, 0). We can apply Coulomb's law and the principle of superposition of forces to find the net force acting on each of the point particles.



Express the net force on the point particle whose charge is q_2 when it is at (8.00 cm, 0):

$$\vec{F}_2(8.00\,\text{cm},0) = \vec{F}_{1,3} + \vec{F}_{2,3} = \frac{kq_1q_3}{r_{1,3}^3}\vec{r}_{1,3} + \frac{kqq_3}{r_{2,3}^3}\vec{r}_{2,3} = kq_3\left(\frac{q_1}{r_{1,3}^3}\vec{r}_{1,3} + \frac{q}{r_{2,3}^3}\vec{r}_{2,3}\right)$$

Substitute numerical values to obtain:

$$(-19.7\,\text{N})\hat{\boldsymbol{i}} = \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(2.00\,\mu\text{C}) \times\left[\frac{5.00\,\mu\text{C}}{(0.0800\,\text{m})^3}(0.0800\,\text{m})\hat{\boldsymbol{i}} + \frac{q}{(0.0400\,\text{m})^3}(0.0400\,\text{m})\hat{\boldsymbol{i}}\right]$$

Solving for q yields:

$$q = \boxed{-3.00\,\mu\text{C}}$$

Remarks: An alternative approach is to equate the electrostatic forces acting on q_2 when it is at (17.8 cm, 0).

35 ••• [SSM] Five identical point charges, each having charge Q, are equally spaced on a semicircle of radius R as shown in Figure 21-37. Find the force (in terms of k, Q, and R) on a charge q located equidistant from the five other charges.

Picture the Problem By considering the symmetry of the array of charged point particles, we can see that the y component of the force on q is zero. We can apply Coulomb's law and the principle of superposition of forces to find the net force acting on q.

Express the net force acting on the point charge q:

$$\vec{F}_q = \vec{F}_{Q\text{ on }x\text{ axis},q} + 2\vec{F}_{Q\text{ at }45°,q}$$

Express the force on point charge q due to the point charge Q on the x axis:

$$\vec{F}_{Q\text{ on }x\text{ axis},q} = \frac{kqQ}{R^2}\hat{\boldsymbol{i}}$$

Express the net force on point charge q due to the point charges at 45°:

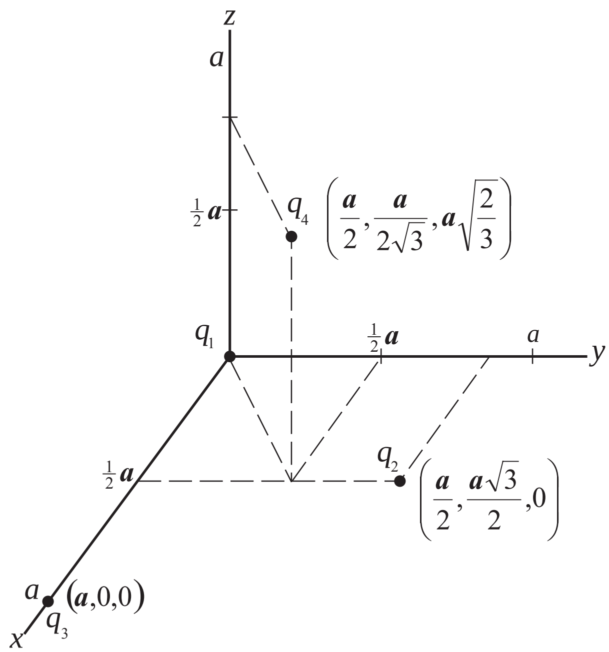
$$2\vec{F}_{Q\text{ at }45°,q} = 2\frac{kqQ}{R^2}\cos 45°\hat{\boldsymbol{i}} = \frac{2}{\sqrt{2}}\frac{kqQ}{R^2}\hat{\boldsymbol{i}}$$

Substitute for $\vec{F}_{Q\text{ on }x\text{ axis},q}$ and $2\vec{F}_{Q\text{ at }45°,q}$ to obtain:

$$\vec{F}_q = \frac{kqQ}{R^2}\hat{\boldsymbol{i}} + \frac{2}{\sqrt{2}}\frac{kqQ}{R^2}\hat{\boldsymbol{i}} = \boxed{\frac{kqQ}{R^2}\left(1+\sqrt{2}\right)\hat{\boldsymbol{i}}}$$

36 ••• The structure of the NH_3 molecule is approximately that of an equilateral tetrahedron, with three H^+ ions forming the base and an N^{3-} ion at the apex of the tetrahedron. The length of each side is 1.64×10^{-10} m. Calculate the electric force that acts on each ion.

Picture the Problem Let the H^+ ions be in the x-y plane with H_1 at (0, 0, 0), H_2 at (a, 0, 0), and H_3 at $\left(\frac{a}{2}, \frac{a\sqrt{3}}{2}, 0\right)$. The N^{-3} ion, with charge q_4 in our notation, is then at $\left(\frac{a}{2}, \frac{a}{2\sqrt{3}}, a\sqrt{\frac{2}{3}}\right)$ where a =1.64 × 10^{-10} m. To simplify our calculations we'll set $ke^2/a^2 = C = 8.56\times10^{-9}\,\text{N}$. We can apply Coulomb's law and the principle of superposition of forces to find the net force acting on each ion.



Express the net force acting on point charge q_1:

$$\vec{F}_1 = \vec{F}_{2,1} + \vec{F}_{3,1} + \vec{F}_{4,1}$$

Find $\vec{F}_{2,1}$:

$$\vec{F}_{2,1} = \frac{kq_1q_2}{r_{2,1}^2}\hat{r}_{2,1} = C\left(-\hat{i}\right) = -C\hat{i}$$

Find $\vec{F}_{3,1}$:

$$\vec{F}_{3,1} = \frac{kq_3q_1}{r_{3,1}^2}\hat{r}_{3,1}$$

$$= C\frac{\left(0-\frac{a}{2}\right)\hat{i} + \left(0-\frac{a\sqrt{3}}{2}\right)\hat{j}}{a}$$

$$= -C\left(\frac{1}{2}\hat{i} + \frac{\sqrt{3}}{2}\hat{j}\right)$$

Noting that the magnitude of point charge q_4 is three times that of the other point charges and that it is negative, express $\vec{F}_{4,1}$:

$$\vec{F}_{4,1} = 3C\hat{r}_{4,1} = -3C\frac{\left(0-\frac{a}{2}\right)\hat{i}+\left(0-\frac{a}{2\sqrt{3}}\right)\hat{j}+\left(0-\frac{a\sqrt{2}}{\sqrt{3}}\right)\hat{k}}{\sqrt{\left(\frac{a}{2}\right)^2+\left(\frac{a}{2\sqrt{3}}\right)^2+\left(\frac{a\sqrt{2}}{\sqrt{3}}\right)^2}}$$

$$= 3C\frac{\left(\frac{a}{2}\right)\hat{i}+\left(\frac{a}{2\sqrt{3}}\right)\hat{j}+\left(\frac{a\sqrt{2}}{\sqrt{3}}\right)\hat{k}}{a} = 3C\left[\left(\frac{1}{2}\right)\hat{i}+\left(\frac{1}{2\sqrt{3}}\right)\hat{j}+\left(\sqrt{\frac{2}{3}}\right)\hat{k}\right]$$

Substitute in the expression for $\vec{F}_1$ to obtain:

$$\vec{F}_1 = -C\hat{i} - C\left(\frac{1}{2}\hat{i}+\frac{\sqrt{3}}{2}\hat{j}\right) + 3C\left[\left(\frac{1}{2}\right)\hat{i}+\left(\frac{1}{2\sqrt{3}}\right)\hat{j}+\left(\sqrt{\frac{2}{3}}\right)\hat{k}\right] = \boxed{C\sqrt{6}\hat{k}}$$

From symmetry considerations:

$$\vec{F}_2 = \vec{F}_3 = \vec{F}_1 = \boxed{C\sqrt{6}\hat{k}}$$

Express the condition that the molecule is in equilibrium:

$$\vec{F}_1 + \vec{F}_2 + \vec{F}_3 + \vec{F}_4 = 0$$

Solve for and evaluate $\vec{F}_4$:

$$\vec{F}_4 = -\left(\vec{F}_1 + \vec{F}_2 + \vec{F}_3\right) = -3\vec{F}_1 = \boxed{-3C\sqrt{6}\hat{k}}$$

The Electric Field

37 • **[SSM]** A point charge of 4.0 μC is at the origin. What are the magnitude and direction of the electric field on the x axis at (*a*) $x = 6.0$ m and (*b*) $x = -10$ m? (*c*) Sketch the function E_x versus x for both positive and negative values of x. (Remember that E_x is negative when $\vec{E}$ points in the $-x$ direction.)

Picture the Problem Let q represent the point charge at the origin and use Coulomb's law for $\vec{E}$ due to a point charge to find the electric field at $x = 6.0$ m and -10 m.

(*a*) Express the electric field at a point P located a distance *x* from a point charge *q*:

$$\vec{E}(x)=\frac{kq}{x^2}\hat{r}_{\mathrm{P},0}$$

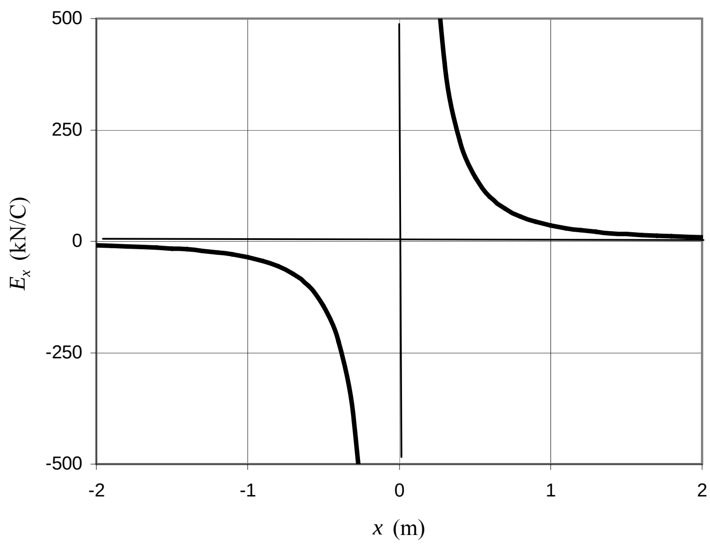
Evaluate this expression for $x = 6.0$ m:

$$\vec{E}(6.0\,\mathrm{m})=\frac{\left(8.988\times10^{9}\,\frac{\mathrm{N\cdot m^2}}{\mathrm{C^2}}\right)(4.0\,\mu\mathrm{C})}{(6.0\,\mathrm{m})^2}\hat{i}=\boxed{(1.0\,\mathrm{kN/C})\hat{i}}$$

(*b*) Evaluate $\vec{E}$ at $x = -10$ m:

$$\vec{E}(-10\,\mathrm{m})=\frac{\left(8.988\times10^{9}\,\frac{\mathrm{N\cdot m^2}}{\mathrm{C^2}}\right)(4.0\,\mu\mathrm{C})}{(10\,\mathrm{m})^2}\left(-\hat{i}\right)=\boxed{(-0.36\,\mathrm{kN/C})\hat{i}}$$

(*c*) The following graph was plotted using a spreadsheet program:



38 • Two point charges, each +4.0 μC, are on the *x* axis; one point charge is at the origin and the other is at $x = 8.0$ m. Find the electric field on the *x* axis at (*a*) $x = -2.0$ m, (*b*) $x = 2.0$ m, (*c*) $x = 6.0$ m, and (*d*) $x = 10$ m. (*e*) At what point on the *x* axis is the electric field zero? (*f*) Sketch E_x versus *x* for $-3.0\text{ m} < x < 11$ m.

Picture the Problem Let *q* represent the point charges of +4.0 μC and use Coulomb's law for $\vec{E}$ due to a point charge and the principle of superposition for fields to find the electric field at the locations specified.

Noting that $q_1 = q_2$, use Coulomb's law and the principle of superposition to express the electric field due to the given charges at point P a distance x from the origin:

$$\vec{E}(x) = \vec{E}_{q_1}(x) + \vec{E}_{q_2}(x) = \frac{kq_1}{x^2}\hat{r}_{q_1,P} + \frac{kq_2}{(8.0\,\mathrm{m} - x)^2}\hat{r}_{q_2,P}$$
$$= kq_1\left(\frac{1}{x^2}\hat{r}_{q_1,P} + \frac{1}{(8.0\,\mathrm{m} - x)^2}\hat{r}_{q_2,P}\right)$$
$$= (36\,\mathrm{kN\cdot m^2/C})\left(\frac{1}{x^2}\hat{r}_{q_1,P} + \frac{1}{(8.0\,\mathrm{m} - x)^2}\hat{r}_{q_2,P}\right)$$

(a) Apply this equation to the point at $x = -2.0$ m:

$$\vec{E}(-2.0\,\mathrm{m}) = (36\,\mathrm{kN\cdot m^2/C})\left[\frac{1}{(2.0\,\mathrm{m})^2}(-\hat{i}) + \frac{1}{(10\,\mathrm{m})^2}(-\hat{i})\right] = \boxed{(-9.4\,\mathrm{kN/C})\hat{i}}$$

(b) Evaluate $\vec{E}$ at $x = 2.0$ m:

$$\vec{E}(2.0\,\mathrm{m}) = (36\,\mathrm{kN\cdot m^2/C})\left[\frac{1}{(2.0\,\mathrm{m})^2}(\hat{i}) + \frac{1}{(6.0\,\mathrm{m})^2}(-\hat{i})\right] = \boxed{(8.0\,\mathrm{kN/C})\hat{i}}$$

(c) Evaluate $\vec{E}$ at $x = 6.0$ m:

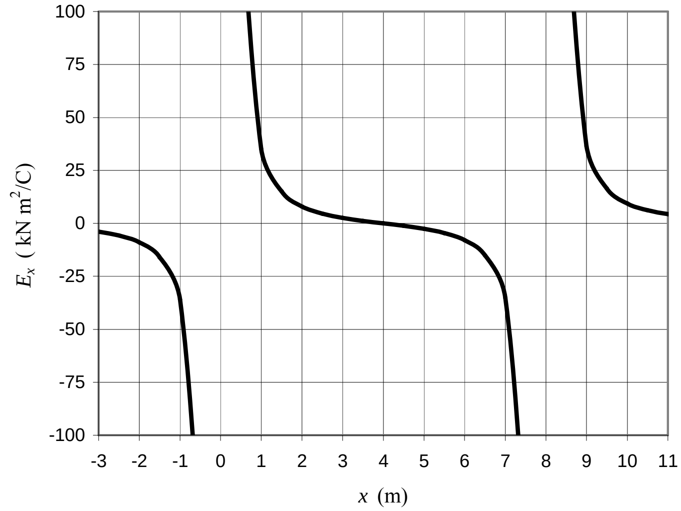
$$\vec{E}(6.0\,\mathrm{m}) = (36\,\mathrm{kN\cdot m^2/C})\left[\frac{1}{(6.0\,\mathrm{m})^2}(\hat{i}) + \frac{1}{(2.0\,\mathrm{m})^2}(-\hat{i})\right] = \boxed{(-8.0\,\mathrm{kN/C})\hat{i}}$$

(d) Evaluate $\vec{E}$ at $x = 10$ m:

$$\vec{E}(10\,\mathrm{m}) = (36\,\mathrm{kN\cdot m^2/C})\left[\frac{1}{(10\,\mathrm{m})^2}(\hat{i}) + \frac{1}{(2.0\,\mathrm{m})^2}(\hat{i})\right] = \boxed{(9.4\,\mathrm{kN/C})\hat{i}}$$

(e) From symmetry considerations: $\vec{E}(4.0\,\mathrm{m}) = \boxed{0}$

(*f*) The following graph was plotted using a spreadsheet program:



39 • When a 2.0-nC point charge is placed at the origin, it experiences an electric force of 8.0×10^{-4} N in the $+y$ direction. (*a*) What is the electric field at the origin? (*b*) What would be the electric force on a –4.0-nC point charge placed at the origin? (*c*) If this force is due to the electric field of a point charge on the *y* axis at *y* = 3.0 cm, what is the value of that charge?

Comment: Is the force related to q_0? 8.0×10^{-4} *N*?

Picture the Problem We can find the electric field at the origin from its definition and the electric force on a point charge placed there using $\vec{F} = q\vec{E}$. We can apply Coulomb's law to find the value of the point charge placed at y = 3 cm.

(*a*) Apply the definition of electric field to obtain:

$$\vec{E}(0,0) = \frac{\vec{F}(0,0)}{q_0} = \frac{\left(8.0\times10^{-4}\text{ N}\right)\hat{j}}{2.0\,\text{nC}}$$
$$= \boxed{\left(4.0\times10^{5}\text{ N/C}\right)\hat{j}}$$

(*b*) The force on a point charge in an electric field is given by:

$$\vec{F}(0,0) = q\vec{E}(0,0)$$
$$= (-4.0\,\text{nC})(400\,\text{kN/C})\hat{j}$$
$$= \boxed{(-1.6\,\text{mN})\hat{j}}$$

(*c*) Apply Coulomb's law to obtain:

$$\frac{kq(-4.0\,\text{nC})}{(0.030\,\text{m})^2}\left(-\hat{j}\right) = (-1.60\,\text{mN})\hat{j}$$

Solving for q yields:

$$q = -\frac{(1.60\,\text{mN})(0.030\,\text{m})^2}{(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(4.0\,\text{nC})} = \boxed{-40\,\text{nC}}$$

40 • The electric field near the surface of Earth points downward and has a magnitude of 150 N/C. (*a*) Compare the magnitude of the upward electric force on an electron with the magnitude of the gravitational force on the electron. (*b*) What charge should be placed on a ping pong ball of mass 2.70 g so that the electric force balances the weight of the ball near Earth's surface?

Comment: DAVID: IN 48 the penny has been replaced by a ping pong ball

Picture the Problem We can compare the electric and gravitational forces acting on an electron by expressing their ratio. Because the ping pong ball is in equilibrium under the influence of the electric and gravitational forces acting on it, we can use the condition for translational equilibrium to find the charge that would have to be placed on it in order to balance Earth's gravitational force on it.

(*a*) Express the magnitude of the electric force acting on the electron:

$$F_e = eE$$

Express the magnitude of the gravitational force acting on the electron:

$$F_g = m_e g$$

The ratio of these forces is:

$$\frac{F_e}{F_g} = \frac{eE}{mg}$$

Substitute numerical values and evaluate F_e/F_g:

$$\frac{F_e}{F_g} = \frac{(1.602\times10^{-19}\,\text{C})(150\,\text{N/C})}{(9.109\times10^{-31}\,\text{kg})(9.81\,\text{m/s}^2)} = 2.69\times10^{12}$$

or

$$F_e = \boxed{(2.69\times10^{12})F_g}$$

Thus, the electric force is greater by a factor of 2.69×10^{12}.

(*b*) Letting the upward direction be positive, apply the condition for static equilibrium to the ping pong ball to obtain:

$$F_e - F_g = 0$$

or

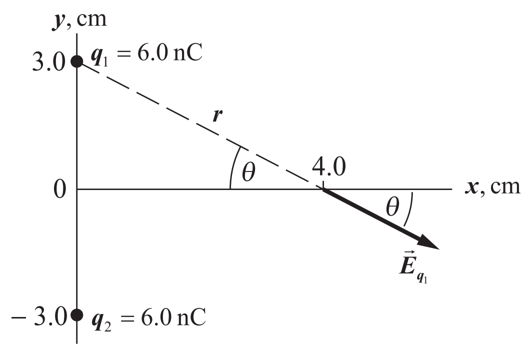
$$-qE - mg = 0 \Rightarrow q = -\frac{mg}{E}$$

Substitute numerical values and evaluate q:

$$q = -\frac{(2.70\times10^{-3}\text{ kg})(9.81\text{m/s}^2)}{150\text{ N/C}} = \boxed{-0.177\text{ mC}}$$

41 •• [SSM] Two point charges q_1 and q_2 both have a charge equal to +6.0 nC and are on the y axis at y_1 = +3.0 cm and y_2 = –3.0 cm respectively. (a) What is the magnitude and direction of the electric field on the x axis at x = 4.0 cm? (b) What is the force exerted on a third charge q_0 = 2.0 nC when it is placed on the x axis at x = 4.0 cm?

Picture the Problem The diagram shows the locations of the point charges q_1 and q_2 and the point on the x axis at which we are to find $\vec{E}$. From symmetry considerations we can conclude that the y component of $\vec{E}$ at any point on the x axis is zero. We can use Coulomb's law for the electric field due to point charges and the principle of superposition for fields to find the field at any point on the x axis and $\vec{F} = q\vec{E}$ to find the force on a point charge q_0 placed on the x axis at x = 4.0 cm.



(a) Letting $q = q_1 = q_2$, express the x component of the electric field due to one point charge as a function of the distance r from either point charge to the point of interest:

$$\vec{E}_x = \frac{kq}{r^2}\cos\theta\,\hat{\boldsymbol{i}}$$

Express $\vec{E}_x$ for both charges:

$$\vec{E}_x = 2\frac{kq}{r^2}\cos\theta\,\hat{\boldsymbol{i}}$$

Substitute for $\cos\theta$ and r, substitute numerical values, and evaluate to obtain:

$$\begin{aligned}\vec{E}(4.0\text{ cm})_x &= 2\frac{kq}{r^2}\frac{0.040\text{ m}}{r}\hat{\boldsymbol{i}} = \frac{2kq(0.040\text{ m})}{r^3}\hat{\boldsymbol{i}} \\ &= \frac{2\left(8.988\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2\right)(6.0\text{ nC})(0.040\text{ m})}{\left[(0.030\text{ m})^2+(0.040\text{ m})^2\right]^{3/2}}\hat{\boldsymbol{i}} \\ &= (34.5\text{ kN/C})\hat{i} = (35\text{ kN/C})\hat{\boldsymbol{i}}\end{aligned}$$

The magnitude and direction of the electric field at $x = 4.0$ cm is:

$$\boxed{35\text{ kN/C @ }0°}$$

(*b*) Apply $\vec{F} = q\vec{E}$ to find the force on a point charge q_0 placed on the x axis at $x = 4.0$ cm:

$$\begin{aligned}\vec{F} &= (2.0\text{ nC})(34.5\text{ kN/C})\hat{\boldsymbol{i}} \\ &= \boxed{(69\ \mu\text{N})\hat{\boldsymbol{i}}}\end{aligned}$$

42 •• A point charge of +5.0 μC is located on the x axis at $x = -3.0$ cm, and a second point charge of –8.0 μC is located on the x axi at $x = +4.0$ cm. Where should a third charge of +6.0 μC be placed so that the electric field at the origin is zero?

Picture the Problem If the electric field at $x = 0$ is zero, both its x and y components must be zero. The only way this condition can be satisfied with point charges of +5.0 μC and −8.0 μC on the x axis is if the point charge +6.0 μC is also on the x axis. Let the subscripts 5, −8, and 6 identify the point charges and their fields. We can use Coulomb's law for $\vec{E}$ due to a point charge and the principle of superposition for fields to determine where the +6.0 μC point charge should be located so that the electric field at $x = 0$ is zero.

Express the electric field at $x = 0$ in terms of the fields due to the point charges of +5.0 μC, −8.0 μC, and +6.0 μC:

$$\begin{aligned}\vec{E}(0) &= \vec{E}_{5\,\mu\text{C}} + \vec{E}_{-8\,\mu\text{C}} + \vec{E}_{6\,\mu\text{C}} \\ &= 0\end{aligned}$$

Substitute for each of the fields to obtain:

$$\frac{kq_5}{r_5^2}\hat{\boldsymbol{r}}_5 + \frac{kq_6}{r_6^2}\hat{\boldsymbol{r}}_6 + \frac{kq_{-8}}{r_{-8}^2}\hat{\boldsymbol{r}}_{-8} = 0$$

or

$$\frac{kq_5}{r_5^2}\hat{\boldsymbol{i}} + \frac{kq_6}{r_6^2}\left(-\hat{\boldsymbol{i}}\right) + \frac{kq_{-8}}{r_{-8}^2}\left(-\hat{\boldsymbol{i}}\right) = 0$$

Divide out the unit vector $\hat{\boldsymbol{i}}$ to obtain:

$$\frac{q_5}{r_5^2}-\frac{q_6}{r_6^2}-\frac{q_{-8}}{r_{-8}^2}=0$$

Substitute numerical values to obtain:

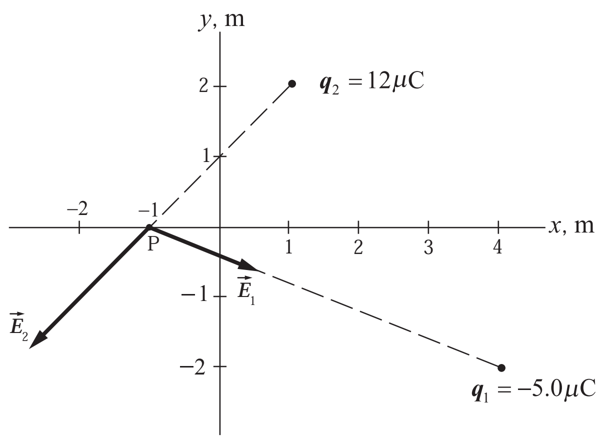
$$\frac{5}{(3.0\,\text{cm})^2}-\frac{6}{r_6^2}-\frac{-8}{(4.0\,\text{cm})^2}=0$$

Solving for r_6 yields:

$$r_6=\boxed{2.4\,\text{cm}}$$

43 •• A –5.0-μC point charge is located at x = 4.0 m, y = –2.0 m and a 12-μC point charge is located at x = 1.0 m, y = 2.0 m. (*a*) Find the magnitude and direction of the electric field at x = –1.0 m, y = 0. (*b*) Calculate the magnitude and direction of the electric force on an electron that is placed at x = –1.0 m, y = 0.

Picture the Problem The diagram shows the electric field vectors at the point of interest P due to the two point charges. We can use Coulomb's law for $\vec{E}$ due to point charges and the superposition principle for electric fields to find $\vec{E}_\text{P}$. We can apply $\vec{F}=q\vec{E}$ to find the force on an electron at (–1.0 m, 0).



(*a*) Express the electric field at (–1.0 m, 0) due to the point charges q_1 and q_2:

$$\vec{E}_\text{P}=\vec{E}_1+\vec{E}_2$$

Substitute numerical values and evaluate $\vec{E}_1$:

$$\vec{E}_1 = \frac{kq_1}{r_{1,\mathrm{P}}^2}\hat{r}_{1,\mathrm{P}} = \frac{(8.988\times10^9\ \mathrm{N\cdot m^2/C^2})(-5.0\,\mu\mathrm{C})}{(5.0\,\mathrm{m})^2+(2.0\,\mathrm{m})^2}\left(\frac{(-5.0\,\mathrm{m})\hat{i}+(2.0\,\mathrm{m})\hat{j}}{\sqrt{(5.0\,\mathrm{m})^2+(2.0\,\mathrm{m})^2}}\right)$$
$$= (-1.55\times10^3\ \mathrm{N/C})(-0.928\,\hat{i}+0.371\,\hat{j})$$
$$= (1.44\,\mathrm{kN/C})\hat{i} + (-0.575\,\mathrm{kN/C})\hat{j}$$

Substitute numerical values and evaluate $\vec{E}_2$:

$$\vec{E}_2 = \frac{kq_2}{r_{2,\mathrm{P}}^2}\hat{r}_{2,\mathrm{P}} = \frac{(8.988\times10^9\ \mathrm{N\cdot m^2/C^2})(12\,\mu\mathrm{C})}{(2.0\,\mathrm{m})^2+(2.0\,\mathrm{m})^2}\left(\frac{(-2.0\,\mathrm{m})\hat{i}+(-2.0\,\mathrm{m})\hat{j}}{\sqrt{(2.0\,\mathrm{m})^2+(2.0\,\mathrm{m})^2}}\right)$$
$$= (13.5\times10^3\ \mathrm{N/C})(-0.707\,\hat{i}-0.707\,\hat{j})$$
$$= (-9.54\,\mathrm{kN/C})\hat{i} + (-9.54\,\mathrm{kN/C})\hat{j}$$

Substitute for $\vec{E}_1$ and $\vec{E}_2$ and simplify to find $\vec{E}_\mathrm{P}$:

$$\vec{E}_\mathrm{P} = (1.44\,\mathrm{kN/C})\hat{i} + (-0.575\,\mathrm{kN/C})\hat{j} + (-9.54\,\mathrm{kN/C})\hat{i} + (-9.54\,\mathrm{kN/C})\hat{j}$$
$$= (-8.10\,\mathrm{kN/C})\hat{i} + (-10.1\,\mathrm{kN/C})\hat{j}$$

The magnitude of $\vec{E}_\mathrm{P}$ is:

$$E_\mathrm{P} = \sqrt{(-8.10\,\mathrm{kN/C})^2+(-10.1\,\mathrm{kN/C})^2} = \boxed{13\,\mathrm{kN/C}}$$

The direction of $\vec{E}_\mathrm{P}$ is:

$$\theta_E = \tan^{-1}\left(\frac{-10.1\,\mathrm{kN/C}}{-8.10\,\mathrm{kN/C}}\right) = \boxed{230°}$$

Note that the angle returned by your calculator for $\tan^{-1}\left(\frac{-10.1\,\mathrm{kN/C}}{-8.10\,\mathrm{kN/C}}\right)$ is the reference angle and must be increased by 180° to yield θ_E.

(*b*) Express and evaluate the force on an electron at point P:

$$\vec{F} = q\vec{E}_\mathrm{P} = (-1.602\times10^{-19}\,\mathrm{C})\left[(-8.10\,\mathrm{kN/C})\hat{i} + (-10.1\,\mathrm{kN/C})\hat{j}\right]$$
$$= (1.30\times10^{-15}\,\mathrm{N})\hat{i} + (1.62\times10^{-15}\,\mathrm{N})\hat{j}$$

Find the magnitude of $\vec{F}$:

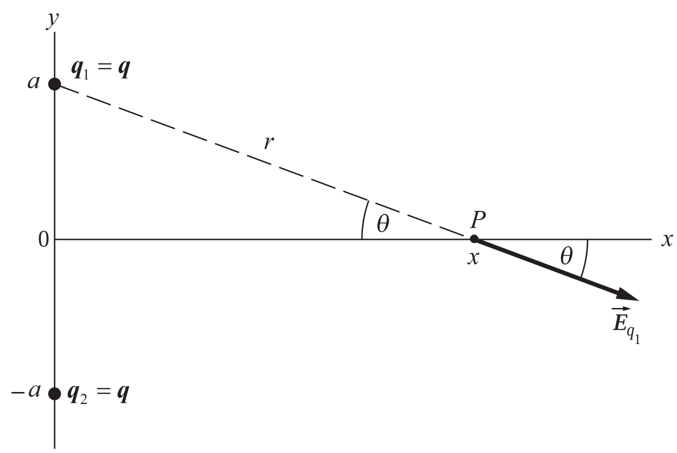
$$F = \sqrt{\left(1.30\times10^{-15}\ \text{N}\right)^2 + \left(1.62\times10^{-15}\ \text{N}\right)^2} = \boxed{2.1\times10^{-15}\ \text{N}}$$

Find the direction of $\vec{F}$:

$$\theta_F = \tan^{-1}\left(\frac{1.62\times10^{-15}\ \text{N}}{1.3\times10^{-15}\ \text{N}}\right) = \boxed{51°}$$

44 •• Two equal positive charges q are on the y axis; one point charge is at $y = +a$ and the other is at $y = -a$. (a) Show that on the x axis the x component of the electric field is given by $E_x = 2kqx/(x^2 + a^2)^{3/2}$. ($b$) Show that near the origin, where x is much smaller than a, $E_x \approx 2kqx/a^3$. (c) Show that for values of x much larger than a, $E_x \approx 2kq/x^2$. Explain why a person might expect this result even without deriving it by taking the appropriate limit.

Picture the Problem The diagram shows the locations of point charges q_1 and q_2 and the point on the x axis at which we are to find $\vec{E}$. From symmetry considerations we can conclude that the y component of $\vec{E}$ at any point on the x axis is zero. We can use Coulomb's law for the electric field due to point charges and the principle of superposition of fields to find the field at any point on the x axis. We can establish the results called for in Parts (b) and (c) by factoring the radicand and using the approximation $1 + \alpha \approx 1$ whenever $\alpha << 1$.



(a) Express the x-component of the electric field due to the point charges at $y = a$ and $y = -a$ as a function of the distance r from either charge to point P:

$$\vec{E}_x = 2\frac{kq}{r^2}\cos\theta\,\hat{\boldsymbol{i}}$$

Substitute for $\cos\theta$ and r to obtain:

$$\vec{E}_x = 2\frac{kq}{r^2}\frac{x}{r}\hat{i} = \frac{2kqx}{r^3}\hat{i} = \frac{2kqx}{\left(x^2+a^2\right)^{3/2}}\hat{i} = \frac{2kqx}{\left(x^2+a^2\right)^{3/2}}\hat{i}$$

The magnitude of $\vec{E}_x$ is:

$$E_x = \boxed{\frac{2kqx}{\left(x^2+a^2\right)^{3/2}}}$$

(*b*) For $|x| << a, x^2 + a^2 \approx a^2$, so:

$$E_x \approx \frac{2kqx}{\left(a^2\right)^{3/2}} = \boxed{\frac{2kqx}{a^3}}$$

(*c*) For $x >> a$, the charges separated by a would appear to be a single charge of magnitude $2q$. Its field would be given by $E_x = \dfrac{2kq}{x^2}$.

Factor the radicand to obtain:

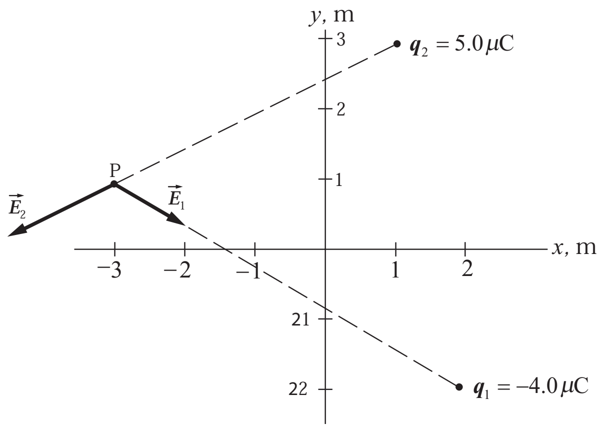
$$E_x = 2kqx\left[x^2\left(1+\frac{a^2}{x^2}\right)\right]^{-3/2}$$

For $a << x$, $1+\dfrac{a^2}{x^2} \approx 1$ and:

$$E_x = 2kqx\left[x^2\right]^{-3/2} = \boxed{\frac{2kq}{x^2}}$$

45 •• A 5.0-μC point charge is located at $x = 1.0$ m, $y = 3.0$ m and a –4.0-μC point charge is located at $x = 2.0$ m, $y = –2.0$ m. (*a*) Find the magnitude and direction of the electric field at $x = –3.0$ m, $y = 1.0$ m. (*b*) Find the magnitude and direction of the force on a proton placed at $x = –3.0$ m, $y = 1.0$ m.

Picture the Problem The diagram shows the electric field vectors at the point of interest P due to the two point charges. We can use Coulomb's law for $\vec{E}$ due to point charges and the superposition principle for electric fields to find $\vec{E}_P$. We can apply $\vec{F} = q\vec{E}$ to find the force on a proton at (–3.0 m, 1.0 m).



(*a*) Express the electric field at (−3.0 m, 1.0 m) due to the point charges q_1 and q_2:

$$\vec{E}_P = \vec{E}_1 + \vec{E}_2$$

Evaluate $\vec{E}_1$:

$$\vec{E}_1 = \frac{kq_1}{r_{1,P}^2}\hat{r}_{1,P} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(-4.0\,\mu\text{C}\right)}{\left(5.0\,\text{m}\right)^2 + \left(3.0\,\text{m}\right)^2}\left(\frac{\left(-5.0\,\text{m}\right)\hat{i} + \left(3.0\,\text{m}\right)\hat{j}}{\sqrt{\left(5.0\,\text{m}\right)^2 + \left(3.0\,\text{m}\right)^2}}\right)$$
$$= \left(-1.06\,\text{kN/C}\right)\left(-0.857\,\hat{i} + 0.514\,\hat{j}\right) = \left(0.907\,\text{kN/C}\right)\hat{i} + \left(-0.544\,\text{kN/C}\right)\hat{j}$$

Evaluate $\vec{E}_2$:

$$\vec{E}_2 = \frac{kq_2}{r_{2,P}^2}\hat{r}_{2,P} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(5.0\,\mu\text{C}\right)}{\left(4.0\,\text{m}\right)^2 + \left(2.0\,\text{m}\right)^2}\left(\frac{\left(-4.0\,\text{m}\right)\hat{i} + \left(-2.0\,\text{m}\right)\hat{j}}{\sqrt{\left(4.0\,\text{m}\right)^2 + \left(2.0\,\text{m}\right)^2}}\right)$$
$$= \left(2.25\,\text{kN/C}\right)\left(-0.894\,\hat{i} - 0.447\,\hat{j}\right) = \left(-2.01\,\text{kN/C}\right)\hat{i} + \left(-1.01\,\text{kN/C}\right)\hat{j}$$

Substitute and simplify to find $\vec{E}_P$:

$$\vec{E}_P = \left(0.908\,\text{kN/C}\right)\hat{i} + \left(-0.544\,\text{kN/C}\right)\hat{j} + \left(-2.01\,\text{kN/C}\right)\hat{i} + \left(-1.01\,\text{kN/C}\right)\hat{j}$$
$$= \left(-1.10\,\text{kN/C}\right)\hat{i} + \left(-1.55\,\text{kN/C}\right)\hat{j}$$

The magnitude of $\vec{E}_P$ is:

$$E_P = \sqrt{\left(1.10\,\text{kN/C}\right)^2 + \left(1.55\,\text{kN/C}\right)^2} = \boxed{1.9\,\text{kN/C}}$$

The direction of $\vec{E}_P$ is:

$$\theta_E = \tan^{-1}\left(\frac{-1.55\,\text{kN/C}}{-1.10\,\text{kN/C}}\right) = \boxed{235°}$$

Note that the angle returned by your calculator for $\tan^{-1}\left(\frac{-1.55\,\text{kN/C}}{-1.10\,\text{kN/C}}\right)$ is the reference angle and must be increased by 180° to yield θ_E.

(*b*) Express and evaluate the force on a proton at point P:

$$\begin{aligned}\vec{F} = q\vec{E}_P &= \left(1.602\times10^{-19}\,\text{C}\right)\left[\left(-1.10\,\text{kN/C}\right)\hat{i} + \left(-1.55\,\text{kN/C}\right)\hat{j}\right]\\ &= \left(-1.76\times10^{-16}\,\text{N}\right)\hat{i} + \left(-2.48\times10^{-16}\,\text{N}\right)\hat{j}\end{aligned}$$

The magnitude of $\vec{F}$ is:

$$F = \sqrt{\left(-1.76\times10^{-16}\,\text{N}\right)^2 + \left(-2.48\times10^{-16}\,\text{N}\right)^2} = \boxed{3.0\times10^{-16}\,\text{N}}$$

The direction of $\vec{F}$ is:

$$\theta_F = \tan^{-1}\left(\frac{-2.48\times10^{-16}\,\text{N}}{-1.76\times10^{-16}\,\text{N}}\right) = \boxed{235°}$$

where, as noted above, the angle returned by your calculator for $\tan^{-1}\left(\frac{-2.48\times10^{-16}\,\text{N}}{-1.76\times10^{-16}\,\text{N}}\right)$ is the reference angle and must be increased by 180° to yield θ_E.

46 •• Two positive point charges, each having a charge Q, are on the y axis, one at $y = +a$ and the other at $y = -a$. (*a*) Show that the electric field strength on the x axis is greatest at the points $x = a/\sqrt{2}$ and $x = -a/\sqrt{2}$ by computing $\partial E_x/\partial x$ and setting the derivative equal to zero. (*b*) Sketch the function E_x versus x using your results for Part (*a*) of this problem and the fact that E_x is approximately $2kqx/a^3$ when x is much smaller than a and E_x is approximately $2kq/x^2$ when x is much larger than a,.

Picture the Problem In Problem 44 it is shown that the electric field on the x axis, due to equal positive charges located at (0, a) and (0,–a), is given by $E_x = 2kqx\left(x^2 + a^2\right)^{-3/2}$. We can identify the locations at which E_x has it greatest values by setting $\partial E_x/\partial x$ equal to zero.

(*a*) Evaluate $\frac{\partial E_x}{\partial x}$ to obtain:

$$\begin{aligned}\frac{\partial E_x}{\partial x} &= \frac{d}{dx}\left[2kqx\left(x^2+a^2\right)^{-3/2}\right] = 2kq\frac{d}{dx}\left[x\left(x^2+a^2\right)^{-3/2}\right]\\ &= 2kq\left[x\frac{d}{dx}\left(x^2+a^2\right)^{-3/2}+\left(x^2+a^2\right)^{-3/2}\right]\\ &= 2kq\left[x\left(-\frac{3}{2}\right)\left(x^2+a^2\right)^{-5/2}(2x)+\left(x^2+a^2\right)^{-3/2}\right]\\ &= 2kq\left[-3x^2\left(x^2+a^2\right)^{-5/2}+\left(x^2+a^2\right)^{-3/2}\right]\end{aligned}$$

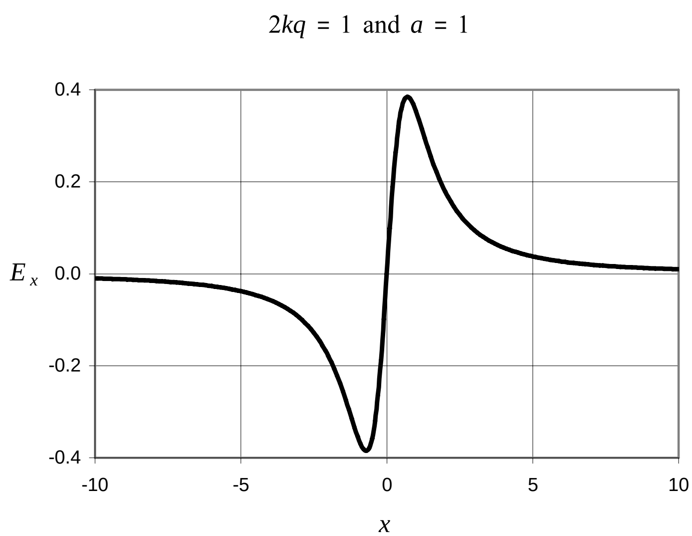
Set this derivative equal to zero for extreme values:

$$-3x^2\left(x^2+a^2\right)^{-5/2}+\left(x^2+a^2\right)^{-3/2}=0$$

Solving for x yields:

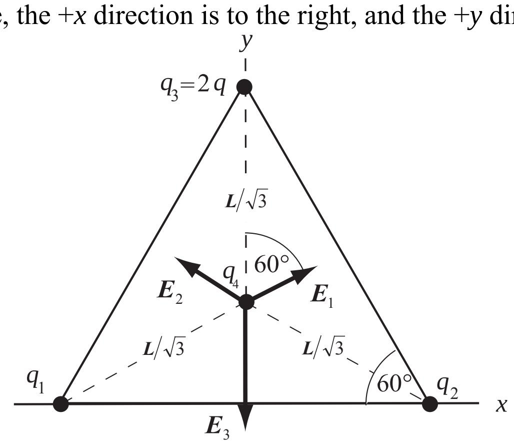
$$x=\boxed{\pm\frac{a}{\sqrt{2}}}$$

(*b*) The following graph was plotted using a spreadsheet program:



47 •• [SSM] Two point particles, each having a charge q, sit on the base of an equilateral triangle that has sides of length L as shown in Figure 21-38. A third point particle that has a charge equal to $2q$ sits at the apex of the triangle. Where must a fourth point particle that has a charge equal to q be placed in order that the electric field at the center of the triangle be zero? (The center is in the plane of the triangle and equidistant from the three vertices.)

Picture the Problem The electric field of the 4th charged point particle must cancel the sum of the electric fields due to the other three charged point particles. By symmetry, the position of the 4th charged point particle must lie on the vertical centerline of the triangle. Using trigonometry, one can show that the center of an equilateral triangle is a distance $L/\sqrt{3}$ from each vertex, where L is the length of the side of the triangle. Note that the x components of the fields due to the base charged particles cancel each other, so we only need concern ourselves with the y components of the fields due to the charged point particles at the vertices of the triangle. Choose a coordinate system in which the origin is at the midpoint of the base of the triangle, the $+x$ direction is to the right, and the $+y$ direction is upward.



Express the condition that must be satisfied if the electric field at the center of the triangle is to be zero:

$$\sum_{\text{i=1 to 4}} \vec{E}_{\text{i}} = 0$$

Substituting for $\vec{E}_1$, $\vec{E}_2$, $\vec{E}_3$, and $\vec{E}_4$ yields:

$$\frac{k(q)}{\left(\frac{L}{\sqrt{3}}\right)^2}\cos 60°\,\hat{\boldsymbol{j}} + \frac{k(q)}{\left(\frac{L}{\sqrt{3}}\right)^2}\cos 60°\,\hat{\boldsymbol{j}} - \frac{k(2q)}{\left(\frac{L}{\sqrt{3}}\right)^2}\,\hat{j} + \frac{kq}{y^2}\,\hat{\boldsymbol{j}} = 0$$

Solving for y yields:

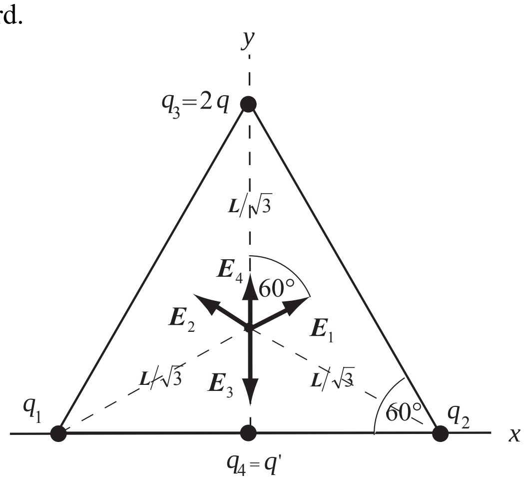
$$y = \pm\frac{L}{\sqrt{3}}$$

The positive solution corresponds to the 4th point particle being a distance $L/\sqrt{3}$ above the base of the triangle, where it produces the same strength and same direction electric field caused by the three charges at the corners of the triangle. So the charged point particle must be placed a distance $L/\sqrt{3}$ below the midpoint of the triangle.

48 •• Two point particles, each having a charge equal to q, sit on the base of an equilateral triangle that has sides of length L as shown in Figure 21-38. A third point particle that has a charge equal to $2q$ sits at the apex of the triangle. A fourth point particle that has charge q' is placed at the midpoint of the baseline making the electric field at the center of the triangle equal to zero. What is the value of q'? (The center is in the plane of the triangle and equidistant from all three vertices.)

Comment: DAVID: In 55 and 56 the solution should either show the center is a distance L/sqrt(3) from the verticies or state that using trig it can be shown?

Picture the Problem The electric field of 4th charge must cancel the sum of the electric fields due to the other three charges. Using trigonometry, one can show that the center of an equilateral triangle is a distance $L/\sqrt{3}$ from each vertex, where L is the length of the side of the triangle. The distance from the center point of the triangle to the midpoint of the base is half this distance. Note that the x components of the fields due to the base charges cancel each other, so we only need concern ourselves with the y components of the fields due to the charges at the vertices of the triangle. Choose a coordinate system in which the origin is at the midpoint of the base of the triangle, the $+x$ direction is to the right, and the $+y$ direction is upward.



Express the condition that must be satisfied if the electric field at the center of the triangle is to be zero:

$$\sum_{i=1\text{ to }4} \vec{E}_i = 0$$

Substituting for $\vec{E}_1$, $\vec{E}_2$, $\vec{E}_3$, and $\vec{E}_4$ yields:

$$\frac{k(q)}{\left(\frac{L}{\sqrt{3}}\right)^2}\cos 60°\,\hat{j}+\frac{k(q)}{\left(\frac{L}{\sqrt{3}}\right)^2}\cos 60°\,\hat{j}-\frac{k(2q)}{\left(\frac{L}{\sqrt{3}}\right)^2}\hat{j}+\frac{kq'}{\left(\frac{L}{2\sqrt{3}}\right)^2}\hat{j}=0$$

Solve for q' to obtain: $$q'=\boxed{\tfrac{1}{4}q}$$

49 ••• Two equal positive point charges $+q$ are on the y axis; one is at $y = +a$ and the other is at $y = –a$. The electric field at the origin is zero. A test charge q_0 placed at the origin will therefore be in equilibrium. (*a*) Discuss the stability of the equilibrium for a positive test charge by considering small displacements from equilibrium along the x axis and small displacements along the y axis. (*b*) Repeat Part (*a*) for a negative test charge. (*c*) Find the magnitude and sign of a charge q_0 that when placed at the origin results in a net force of zero on each of the three charges.

Picture the Problem We can determine the stability of the equilibrium in Part (*a*) and Part (*b*) by considering the forces the equal point charges q at $y = +a$ and $y = -a$ exert on the test charge when it is given a small displacement along either the x or y axis. (*c*) The application of Coulomb's law in Part (*c*) will lead to the magnitude and sign of the charge that must be placed at the origin in order that a net force of zero is experienced by each of the three point charges.

(*a*) Because E_x is in the x direction, a positive test charge that is displaced from (0, 0) in either the $+x$ direction or the $-x$ direction will experience a force pointing away from the origin and accelerate in the direction of the force. Consequently, the equilibrium at (0,0) is unstable for a small displacement along the x axis.

If the positive test charge is displaced in the direction of increasing y (the $+y$ direction), the charge at $y = +a$ will exert a greater force than the charge at $y = -a$, and the net force is then in the $-y$ direction; i.e., it is a restoring force. Similarly, if the positive test charge is displaced in the direction of decreasing y (the $-y$ direction), the charge at $y = -a$ will exert a greater force than the charge at $y = -a$, and the net force is then in the $-y$ direction; i.e., it is a restoring force. Consequently, the equilibrium at (0,0) is stable for a small displacement along the y axis.

(*b*) Following the same arguments as in Part (*a*), one finds that, for a negative test charge, the equilibrium is stable at (0,0) for displacements along the x axis and unstable for displacements along the y axis.

(*c*) Express the net force acting on the charge at $y = +a$:

$$\sum F_{q\text{ at }y=+a} = \frac{kqq_0}{a^2} + \frac{kq^2}{(2a)^2} = 0$$

Solve for q_0 to obtain:

$$q_0 = \boxed{-\tfrac{1}{4}q}$$

Remarks: In Part (*c*), we could just as well have expressed the net force acting on the charge at *y* = –*a*. Due to the symmetric distribution of the charges at *y* = –*a* and *y* = +*a*, summing the forces acting on q_0 at the origin does not lead to a relationship between q_0 and *q*.

50 ••• Two positive point charges $+q$ are on the y axis at $y = +a$ and $y = -a$. A bead of mass m and charge $-q$ slides without friction along a taut thread that runs along the x axis. Let x be the position of the bead. (*a*) Show that for $x << a$, the bead experiences a linear restoring force (a force that is proportional to x and directed toward the equilibrium position at $x = 0$) and therefore undergoes simple harmonic motion. (*b*) Find the period of the motion.

Picture the Problem In Problem 44 it is shown that the electric field on the x axis, due to equal positive point charges located at $(0, a)$ and $(0, -a)$, is given by $E_x = 2kqx\left(x^2 + a^2\right)^{-3/2}$. We can use $T = 2\pi\sqrt{m/k'}$ to express the period of the motion of the bead in terms of the restoring constant k'.

(*a*) Express the force acting on the bead when its displacement from the origin is x:

$$F_x = -qE_x = -\frac{2kq^2x}{\left(x^2 + a^2\right)^{3/2}}$$

Factor a^2 from the denominator to obtain:

$$F_x = -\frac{2kq^2x}{a^2\left(\dfrac{x^2}{a^2} + 1\right)^{3/2}}$$

For $x << a$:

$$F_x = \boxed{-\frac{2kq^2}{a^3}x}$$

That is, the bead experiences a linear restoring force.

(*b*) Express the period of a simple harmonic oscillator:

$$T = 2\pi\sqrt{\frac{m}{k'}}$$

Obtain k' from our result in Part (*a*):

$$k' = \frac{2kq^2}{a^3}$$

Substitute for k' and simplify to obtain:

$$T = 2\pi\sqrt{\frac{m}{\frac{2kq^2}{a^3}}} = \boxed{2\pi\sqrt{\frac{ma^3}{2kq^2}}}$$

Point Charges in Electric Fields

51 •• **[SSM]** The acceleration of a particle in an electric field depends on q/m (the charge-to-mass ratio of the particle). (*a*) Compute q/m for an electron. (*b*) What is the magnitude and direction of the acceleration of an electron in a uniform electric field that has a magnitude of 100 N/C? (*c*) Compute the time it takes for an electron placed at rest in a uniform electric field that has a magnitude of 100 N/C to reach a speed of $0.01c$. (When the speed of an electron approaches the speed of light c, relativistic kinematics must be used to calculate its motion, but at speeds of $0.01c$ or less, non-relativistic kinematics is sufficiently accurate for most purposes.) (*d*) How far does the electron travel in that time?

Picture the Problem We can use Newton's second law of motion to find the acceleration of the electron in the uniform electric field and constant-acceleration equations to find the time required for it to reach a speed of $0.01c$ and the distance it travels while acquiring this speed.

(*a*) Use data found at the back of your text to compute e/m for an electron:

$$\frac{e}{m_e} = \frac{1.602\times10^{-19}\text{ C}}{9.109\times10^{-31}\text{ kg}} = \boxed{1.76\times10^{11}\text{ C/kg}}$$

(*b*) Apply Newton's second law to relate the acceleration of the electron to the electric field:

$$a = \frac{F_{\text{net}}}{m_e} = \frac{eE}{m_e}$$

Substitute numerical values and evaluate a:

$$a = \frac{(1.602\times10^{-19}\text{ C})(100\text{ N/C})}{9.109\times10^{-31}\text{ kg}} = 1.759\times10^{13}\text{ m/s}^2 = \boxed{1.76\times10^{13}\text{ m/s}^2}$$

The direction of the acceleration of an electron is opposite the electric field.

(*c*) Using the definition of acceleration, relate the time required for an electron to reach $0.01c$ to its acceleration:

$$\Delta t = \frac{v}{a} = \frac{0.01c}{a}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{0.01\left(2.998\times10^{8}\ \text{m/s}\right)}{1.759\times10^{13}\ \text{m/s}^2} = 0.1704\ \mu\text{s}$$

$$= \boxed{0.2\ \mu\text{s}}$$

(*d*) Use a constant-acceleration equation to express the distance the electron travels in a given time interval:

$$\Delta x = v_i\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

or, because $v_i = 0$,

$$\Delta x = \tfrac{1}{2}a(\Delta t)^2$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \tfrac{1}{2}\left(1.759\times10^{13}\ \text{m/s}^2\right)\left(0.1704\ \mu\text{s}\right)^2$$

$$= \boxed{0.3\ \text{m}}$$

52 • The acceleration of a particle in an electric field depends on the charge-to-mass ratio of the particle. (*a*) Compute q/m for a proton, and find its acceleration in a uniform electric field that has a magnitude of 100 N/C. (*b*) Find the time it takes for a proton initially at rest in such a field to reach a speed of $0.01c$ (where c is the speed of light). (When the speed of an electron approaches the speed of light c, relativistic kinematics must be used to calculate its motion, but at speeds of $0.01c$ or less, non-relativistic kinematics is sufficiently accurate for most purposes.)

Picture the Problem We can use Newton's second law of motion to find the acceleration of the proton in the uniform electric field and constant-acceleration equations to find the time required for it to reach a speed of $0.01c$ and the distance it travels while acquiring this speed.

(*a*) Use data found at the back of your text to compute e/m for an electron:

$$\frac{e}{m_p} = \frac{1.602\times10^{-19}\ \text{C}}{1.673\times10^{-27}\ \text{kg}}$$

$$= \boxed{9.58\times10^{7}\ \text{C/kg}}$$

Apply Newton's second law to relate the acceleration of the electron to the electric field:

$$a = \frac{F_{\text{net}}}{m_p} = \frac{eE}{m_p}$$

Substitute numerical values and evaluate a:

$$a = \frac{\left(1.602\times10^{-19}\ \text{C}\right)\left(100\ \text{N/C}\right)}{1.673\times10^{-27}\ \text{kg}}$$

$$= 9.576\times10^{9}\ \text{m/s}^2$$

$$= \boxed{9.58\times10^{9}\ \text{m/s}^2}$$

The direction of the acceleration of a proton is in the direction of the electric field.

(*b*) Using the definition of acceleration, relate the time required for an electron to reach $0.01c$ to its acceleration:

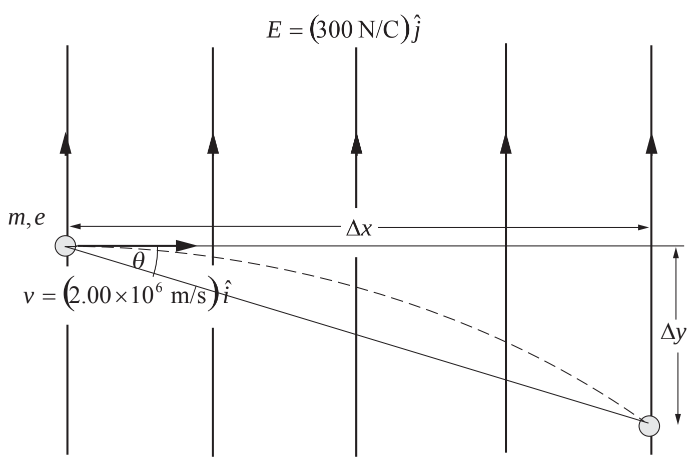
$$\Delta t = \frac{v}{a} = \frac{0.01c}{a}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{0.01\left(2.998\times10^{8}\ \text{m/s}\right)}{9.576\times10^{9}\ \text{m/s}^{2}} = \boxed{0.3\,\text{ms}}$$

53 • An electron has an initial velocity of 2.00×10^6 m/s in the $+x$ direction. It enters a region that has a uniform electric field $\vec{\boldsymbol{E}} = (300\ \text{N/C})\hat{\boldsymbol{j}}$. (*a*) Find the acceleration of the electron. (*b*) How long does it take for the electron to travel 10.0 cm in the *x* direction in the region that has the field? (*c*) Through what angle, and in what direction, is the electron deflected while traveling the 10.0 cm in the *x* direction?

Picture the Problem The electric force acting on the electron is opposite the direction of the electric field. We can apply Newton's second law to find the electron's acceleration and use constant acceleration equations to find how long it takes the electron to travel a given distance and its deflection during this interval of time. Finally, we can use the pictorial representation to obtain an expression for the angle through which the electron is deflected while traveling 10.0 cm in the *x* direction.



(*a*) Use Newton's second law to relate the acceleration of the electron first to the net force acting on it and then the electric field in which it finds itself:

$$\vec{a} = \frac{\vec{F}_{\text{net}}}{m_e} = \frac{-e\vec{E}}{m_e}$$

Substitute numerical values and evaluate $\vec{a}$:

$$\vec{a} = -\frac{1.602\times10^{-19}\ \text{C}}{9.109\times10^{-31}\ \text{kg}}(300\ \text{N/C})\hat{j}$$
$$= \left(-5.276\times10^{13}\ \text{m/s}^2\right)\hat{j}$$
$$= \boxed{\left(-5.28\times10^{13}\ \text{m/s}^2\right)\hat{j}}$$

(*b*) Relate the time to travel a given distance in the *x* direction to the electron's speed in the *x* direction:

$$\Delta t = \frac{\Delta x}{v_x} = \frac{0.100\ \text{m}}{2.00\times10^{6}\ \text{m/s}} = \boxed{50.0\ \text{ns}}$$

(*c*) The angle through which the electron is deflected as it travels a horizontal distance Δx is given by:

$$\theta = \tan^{-1}\left[\frac{\Delta y}{\Delta x}\right]$$

where Δy is its vertical deflection.

Using a constant-acceleration equation, relate the vertical deflection of the electron to its acceleration and the elapsed time:

$$\Delta y = \tfrac{1}{2}a_y(\Delta t)^2$$

Substituting for Δy and simplifying yields:

$$\theta = \tan^{-1}\left[\frac{\frac{1}{2}a_y(\Delta t)^2}{\Delta x}\right] = \tan^{-1}\left[\frac{a_y(\Delta t)^2}{2\Delta x}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left[\frac{\left(5.28\times10^{13}\ \text{m/s}^2\right)(50.0\ \text{ns})^2}{2(10.0\ \text{cm})}\right]$$
$$= \boxed{33.4°}$$

Because the acceleration of the electron is downward and it was moving horizontally initially, it is deflected $\boxed{\text{downward}}$.

54 •• An electron is released from rest in a weak electric field $\vec{E} = \left(-1.50\times10^{-10}\ \text{N/C}\right)\hat{j}$. After the electron has traveled a vertical distance of 1.0 μm, what is its speed? (Do not neglect the gravitational force on the electron.)

Comment: DAVID: Note changes in 62.

Picture the Problem Because the electric field is in the $-y$ direction, the force it exerts on the electron is in the $+y$ direction. Applying Newton's second law to the electron will yield an expression for the acceleration of the electron in the y direction. We can then use a constant-acceleration equation to relate its speed to its acceleration and the distance it has traveled.

Apply $\sum F_y = ma_y$ to the electron to obtain:

$$F_E - F_g = ma_y$$

or, because $F_E = eE$ and $F_g = mg$,

$$eE - mg = ma_y$$

Solving for a_y yields:

$$a_y = \frac{eE}{m} - g$$

Use a constant-acceleration equation to relate the speed of the electron to its acceleration and the distance it travels:

$$v_y^2 = v_0^2 + 2a_y\Delta y$$

or, because the electron starts at rest,

$$v_y^2 = 2a_y\Delta y \Rightarrow v_y = \sqrt{2a_y\Delta y}$$

Substitute for a_y in the expression for v_y:

$$v_y = \sqrt{2\left(\frac{eE}{m} - g\right)\Delta y}$$

Substitute numerical values and evaluate v_y:

$$v_y = \sqrt{2\left[\frac{\left(1.602\times10^{-19}\text{ C}\right)\left(1.50\times10^{-10}\text{ N/C}\right)}{9.109\times10^{-31}\text{ kg}} - 9.81\text{ m/s}^2\right]\left(1.0\times10^{-6}\text{ m}\right)}$$

$$= \boxed{5.8\text{ mm/s}}$$

55 •• A 2.00-g charged particle is released from rest in a region that has a uniform electric field $\vec{E} = (300\text{ N/C})\hat{i}$. After traveling a distance of 0.500 m in this region, the particle has a kinetic energy of 0.120 J. Determine the charge of the particle.

Picture the Problem We can apply the work-kinetic energy theorem to relate the change in the object's kinetic energy to the net force acting on it. We can express the net force acting on the charged body in terms of its charge and the electric field.

Using the work-kinetic energy theorem, express the kinetic energy of the object in terms of the net force acting on it and its displacement:

$$W = \Delta K = F_{\text{net}}\Delta x$$

Relate the net force acting on the charged particle to the electric field:

$$F_{\text{net}} = qE$$

Substitute for F_{net} to obtain:

$$\Delta K = K_{\text{f}} - K_{\text{i}} = qE\Delta x$$

or, because Ki = 0,

$$K_{\text{f}} = qE\Delta x \Rightarrow q = \frac{K_{\text{f}}}{E\Delta x}$$

Substitute numerical values and evaluate q:

$$q = \frac{0.120\,\text{J}}{(300\,\text{N/C})(0.500\,\text{m})} = \boxed{800\,\mu\text{C}}$$

56 •• A charged particle leaves the origin with a speed of 3.00×10^6 m/s at an angle of 35º above the x axis. A uniform electric field given by $\vec{\boldsymbol{E}} = -E_0\hat{\boldsymbol{j}}$ exists throughout the region. Find E_0 such that the particle will cross the x axis at $x = 1.50$ cm if the particle is (a) an electron, and (b) a proton.

Picture the Problem We can use constant-acceleration equations to express the x and y coordinates of the particle in terms of the parameter t and Newton's second law to express the constant acceleration in terms of the electric field. Eliminating t will yield an equation for y as a function of x, q, and m that we can solve for E_y.

Express the x and y coordinates of the particle as functions of time:

$$x = (v\cos\theta)t$$

and

$$y = (v\sin\theta)t - \tfrac{1}{2}a_y t^2$$

Apply Newton's second law to relate the acceleration of the particle to the net force acting on it:

$$a_y = \frac{F_{\text{net,y}}}{m} = \frac{qE_0}{m}$$

Substitute in the y-coordinate equation to obtain:

$$y = (v\sin\theta)t - \frac{qE_0}{2m}t^2$$

Eliminate the parameter t between the two equations to obtain:

$$y = (\tan\theta)x - \frac{qE_0}{2mv^2\cos^2\theta}x^2$$

Set $y = 0$ and solve for E_0 to obtain:

$$E_0 = \frac{mv^2 \sin 2\theta}{qx}$$

Substitute the non-particle-specific data to obtain:

$$E_0 = \frac{m\left(3.00\times10^6\ \text{m/s}\right)^2 \sin 70°}{q(0.0150\,\text{m})} = \left(5.638\times10^{14}\ \text{m/s}^2\right)\frac{m}{q}$$

(*a*) Substitute for the mass and charge of an electron and evaluate E_0:

$$E_0 = \left(5.638\times10^{14}\ \text{m/s}^2\right)\frac{9.109\times10^{-31}\ \text{kg}}{-1.602\times10^{-19}\,\text{C}} = \boxed{-3.2\,\text{kN/C}}$$

(*b*) Substitute for the mass and charge of a proton and evaluate E_0:

$$E_0 = \left(5.64\times10^{14}\ \text{m/s}^2\right)\frac{1.673\times10^{-27}\ \text{kg}}{1.602\times10^{-19}\,\text{C}} = \boxed{5.9\,\text{MN/C}}$$

57 •• [SSM] An electron starts at the position shown in Figure 21-39 with an initial speed $v_0 = 5.00 \times 10^6$ m/s at 45º to the x axis. The electric field is in the $+y$ direction and has a magnitude of 3.50×10^3 N/C. The black lines in the figure are charged metal plates. On which plate and at what location will the electron strike?

Picture the Problem We can use constant-acceleration equations to express the x and y coordinates of the electron in terms of the parameter t and Newton's second law to express the constant acceleration in terms of the electric field. Eliminating t will yield an equation for y as a function of x, q, and m. We can decide whether the electron will strike the upper plate by finding the maximum value of its y coordinate. Should we find that it does not strike the upper plate, we can determine where it strikes the lower plate by setting $y(x) = 0$. Ignore any effects of gravitational forces.

Express the x and y coordinates of the electron as functions of time:

$$x = (v_0 \cos\theta)t$$

and

$$y = (v_0 \sin\theta)t - \tfrac{1}{2}a_y t^2$$

Apply Newton's second law to relate the acceleration of the electron to the net force acting on it:

$$a_y = \frac{F_{\text{net},y}}{m_e} = \frac{eE_y}{m_e}$$

Substitute in the y-coordinate equation to obtain:

$$y = (v_0 \sin\theta)t - \frac{eE_y}{2m_e}t^2$$

Eliminate the parameter t between the two equations to obtain:

$$y(x) = (\tan\theta)x - \frac{eE_y}{2m_e v_0^2 \cos^2\theta}x^2 \quad (1)$$

To find y_{max}, set $dy/dx = 0$ for extrema:

$$\frac{dy}{dx} = \tan\theta - \frac{eE_y}{m_e v_0^2 \cos^2\theta}x'$$
$$= 0 \text{ for extrema}$$

Solve for x' to obtain:

$$x' = \frac{m_e v_0^2 \sin 2\theta}{2eE_y} \text{ (See remark below.)}$$

Substitute x' in $y(x)$ and simplify to obtain y_{max}:

$$y_{\text{max}} = \frac{m_e v_0^2 \sin^2\theta}{2eE_y}$$

Substitute numerical values and evaluate y_{max}:

$$y_{\text{max}} = \frac{(9.109\times10^{-31}\text{ kg})(5.00\times10^{6}\text{ m/s})^2 \sin^2 45°}{2(1.602\times10^{-19}\text{ C})(3.50\times10^{3}\text{ N/C})} = 1.02\text{ cm}$$

Because the plates are separated by 2 cm, the electron does not strike the upper plate.

To determine where the electron will strike the lower plate, set $y = 0$ in equation (1) and solve for x to obtain:

$$x = \frac{m_e v_0^2 \sin 2\theta}{eE_y}$$

Substitute numerical values and evaluate x:

$$x = \frac{(9.109\times10^{-31}\text{ kg})(5.00\times10^{6}\text{ m/s})^2 \sin 90°}{(1.602\times10^{-19}\text{ C})(3.50\times10^{3}\text{ N/C})} = \boxed{4.1\text{ cm}}$$

Remarks: x' is an extremum, that is, either a maximum or a minimum. To show that it is a maximum we need to show that d^2y/dx^2, evaluated at x', is negative. A simple alternative is to use your graphing calculator to show that the graph of $y(x)$ is a maximum at x'. Yet another alternative is to recognize that, because equation (1) is quadratic and the coefficient of x^2 is negative, its graph is a parabola that opens downward.

58 •• An electron that has a kinetic energy equal to 2.00×10^{-16} J is moving to the right along the axis of a cathode-ray tube as shown in Figure 21-40. An electric field $\vec{E} = \left(2.00\times10^{4}\text{ N/C}\right)\hat{j}$ exists in the region between the deflection plates; and no electric field ($\vec{E} = 0$) exists outside this region. (*a*) How far is the electron from the axis of the tube when it exits the region between the plates? (*b*) At what angle is the electron moving, with respect to the axis, after exiting the region between the plates? (*c*) At what distance from the axis will the electron strike the fluorescent screen?

Picture the Problem The trajectory of the electron while it is in the electric field is parabolic (its acceleration is downward and constant) and its trajectory, once it is out of the electric field is, if we ignore the small gravitational force acting on it, linear. We can use constant-acceleration equations and Newton's second law to express the electron's x and y coordinates parametrically and then eliminate the parameter t to express $y(x)$. We can find the angle with the horizontal at which the electron leaves the electric field from the x and y components of its velocity and its total vertical deflection by summing its deflections over the first 4 cm and the final 12 cm of its flight.

(*a*) Using a constant-acceleration equation, express the x and y coordinates of the electron as functions of time:

$$x(t) = v_0 t$$
and
$$y(t) = v_{0,y}t + \tfrac{1}{2}a_y t^2$$

Because $v_{0,y} = 0$:

$$x(t) = v_0 t \qquad (1)$$
and
$$y(t) = \tfrac{1}{2}a_y t^2$$

Using Newton's second law, relate the acceleration of the electron to the electric field:

$$a_y = \frac{F_{\text{net}}}{m_e} = \frac{-eE_y}{m_e}$$

Substituting for a_y gives:

$$y(t) = -\frac{eE_y}{2m_e}t^2 \qquad (2)$$

Eliminate the parameter t between equations (1) and (2) to obtain:

$$y(x) = -\frac{eE_y}{2m_e v_0^2}x^2 = -\frac{eE_y}{4K}x^2$$

Substitute numerical values and evaluate y(4 cm):

$$y(0.04\,\text{m}) = -\frac{(1.602\times10^{-19}\,\text{C})(2.00\times10^{4}\,\text{N/C})(0.0400\,\text{m})^2}{4(2.00\times10^{-16}\,\text{J})} = \boxed{-6.40\,\text{mm}}$$

(b) The angle at which the electron is moving, with respect to the axis, after exiting the region between the plates is given by:

$$\theta = \tan^{-1}\left(\frac{v_y}{v_x}\right) = \tan^{-1}\left(\frac{v_y}{v_0}\right)$$

Using a constant-acceleration equation, express v_y as a function of the electron's acceleration and its time in the electric field:

$$v_y = v_{0,y} + a_y t$$

or, because $v_{0,y} = 0$

$$v_y = a_y t = \frac{F_{\text{net},y}}{m_e} t = -\frac{eE_y}{m_e}\frac{x}{v_0}$$

Substitute for v_y to obtain:

$$\theta = \tan^{-1}\left(-\frac{eE_y x}{m_e v_0^2}\right) = \tan^{-1}\left(-\frac{eE_y x}{2K}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left[-\frac{(1.602\times10^{-19}\,\text{C})(2.00\times10^{4}\,\text{N/C})(0.0400\,\text{m})}{2(2.00\times10^{-16}\,\text{J})}\right] = \boxed{-17.8°}$$

(c) Express the total vertical displacement of the electron:

$$y_{\text{total}} = y_{4\,\text{cm}} + y_{12\,\text{cm}}$$

Relate the horizontal and vertical distances traveled to the screen after leaving the region between the plates to the horizontal and vertical components of its velocity:

$$x = v_0 \Delta t$$

and

$$y = v_y \Delta t$$

Eliminate Δt from these equations to obtain:

$$y = \left(\frac{v_y}{v_0}\right)x = (\tan\theta)x$$

Substitute numerical values and evaluate y:

$$y = [\tan(-17.7°)](0.120\,\text{m}) = -3.83\,\text{cm}$$

Substitute for $y_{4\text{ cm}}$ and $y_{12\text{ cm}}$ and evaluate y_{total}:

$$y_{\text{total}} = -0.640\,\text{cm} - 3.83\,\text{cm}$$
$$= \boxed{-4.47\,\text{cm}}$$

That is, the electron will strike the fluorescent screen 4.47 cm below the horizontal axis.

Dipoles

59 • Two point charges, $q_1 = 2.0$ pC and $q_2 = -2.0$ pC, are separated by 4.0 μm. (*a*) What is the magnitude of the dipole moment of this pair of charges? (*b*) Sketch the pair and show the direction of the dipole moment.

Picture the Problem We can use its definition to find the dipole moment of this pair of charges.

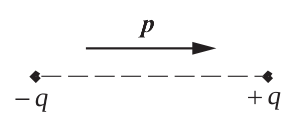
(*a*) Apply the definition of electric dipole moment to obtain:

$$\vec{\boldsymbol{p}} = q\vec{\boldsymbol{L}}$$

and

$$p = (2.0\,\text{pC})(4.0\,\mu\text{m})$$
$$= \boxed{8.0\times10^{-18}\,\text{C}\cdot\text{m}}$$

(*b*) If we assume that the dipole is oriented as shown to the right, then $\vec{\boldsymbol{p}}$ is to the right; pointing from the negative charge toward the positive charge.



60 • A dipole of moment 0.50 *e*·nm is placed in a uniform electric field that has a magnitude of 4.0×10^4 N/C. What is the magnitude of the torque on the dipole when (*a*) the dipole is aligned with the electric field, (*b*) the dipole is transverse to (perpendicular to) the electric field, and (*c*) the dipole makes an angle of 30º with the direction of the electric field? (*d*) Defining the potential energy to be zero when the dipole is transverse to the electric field, find the potential energy of the dipole for the orientations specified in Parts (*a*) and (*c*).

Picture the Problem The torque on an electric dipole in an electric field is given by $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{p}}\times\vec{\boldsymbol{E}}$ and the potential energy of the dipole by $U = -\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{E}}$.

Using its definition, express the torque on a dipole moment in a uniform electric field:

$$\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{p}}\times\vec{\boldsymbol{E}} \Rightarrow \tau = pE\sin\theta$$

where θ is the angle between the electric dipole moment and the electric field.

(*a*) Evaluate τ for θ = 0°:

$$\tau(0°) = pE\sin 0° = \boxed{0}$$

(*b*) Evaluate τ for θ = 90°:

$$\tau(90°) = (0.50\,e\cdot\text{nm})(4.0\times10^{4}\ \text{N/C})\sin 90° = \boxed{3.2\times10^{-24}\ \text{N}\cdot\text{m}}$$

(*c*) Evaluate τ for θ = 30°:

$$\tau(30°) = (0.50\,e\cdot\text{nm})(4.0\times10^{4}\ \text{N/C})\sin 30° = \boxed{1.6\times10^{-24}\ \text{N}\cdot\text{m}}$$

(*d*) Using its definition, express the potential energy of a dipole in an electric field:

$$U = -\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{E}} = -pE\cos\theta$$

Evaluate U for θ = 0°:

$$U(0°) = -(0.50\,e\cdot\text{nm})(4.0\times10^{4}\ \text{N/C})\cos 0° = \boxed{-3.2\times10^{-24}\ \text{J}}$$

Evaluate U for θ = 30°:

$$U(30°) = -(0.50\,e\cdot\text{nm})(4.0\times10^{4}\ \text{N/C})\cos 30° = \boxed{-2.8\times10^{-24}\ \text{J}}$$

General Problems

61 • [SSM] Show that it is only possible to place one isolated proton in an ordinary empty coffee cup by considering the following situation. Assume the first proton is fixed at the bottom of the cup. Determine the distance directly above this proton where a second proton would be in equilibrium. Compare this distance to the depth of an ordinary coffee cup to complete the argument.

Comment: DAVID: My coffee mug is more than 5 in high, so I changed mug to cup.

Comment: At close distances, protons will bind together by the strong nuclear force. This question confuses students.

Comment: To the best of my knowledge, Helium-2 does not exist.

Picture the Problem Equilibrium of the second proton requires that the sum of the electric and gravitational forces acting on it be zero. Let the upward direction be the +*y* direction and apply the condition for equilibrium to the second proton.

Apply $\sum F_y = 0$ to the second proton:

$$\vec{\boldsymbol{F}}_\text{e} + \vec{\boldsymbol{F}}_\text{g} = 0$$

or

$$\frac{kq_\text{p}^2}{h^2} - m_\text{p}g = 0 \Rightarrow h = \sqrt{\frac{kq_\text{p}^2}{m_\text{p}g}}$$

Substitute numerical values and evaluate h:

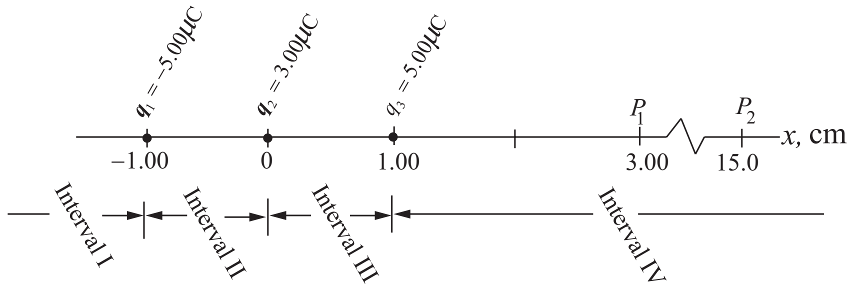
$$h = \sqrt{\frac{\left(8.988\times 10^{9}\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.602\times 10^{-19}\ \text{C}\right)^2}{\left(1.673\times 10^{-27}\ \text{kg}\right)\left(9.81\ \text{m/s}^2\right)}} \approx 12\ \text{cm} \approx 5\ \text{in}$$

This separation of about 5 in is greater than the height of a typical coffee cup. Thus the first proton will repel the second one out of the cup and the maximum number of protons in the cup is one.

62 •• Point charges of $-5.00\ \mu$C, $+3.00\mu$C, and $+5.00\ \mu$C are located on the x axis at $x = -1.00$ cm, $x = 0$, and $x = +1.00$ cm, respectively. Calculate the electric field on the x axis at $x = 3.00$ cm and at $x = 15.0$ cm. Are there any points on the x axis where the magnitude of the electric field is zero? If so, where are those points?

Comment: DAVID: In the second part of 76 the ISM solution is invalid. I get solutions at x = -6.95 cm and +4.17 cm

Picture the Problem The locations of the point charges q_1, q_2 and q_3 and the points P_1 and P_2 at which we are to calculate the electric field are shown in the diagram. From the diagram it is evident that $\vec{E}$ along the axis has no y component. (*a*) We can use Coulomb's law for $\vec{E}$ due to a point charge and the superposition principle for electric fields to find $\vec{E}$ at points P_1 and P_2. (*b*) To decide whether there are any points on the x axis where the magnitude of the electric field is zero we need to consider the intervals (identified on the following pictorial representation) I ($x < -1.00$ cm), II (-1.00 cm $< x < 0$), III ($0 < x < 1.00$ cm), and IV (1.00 cm $< x$). Throughout interval II, the three electric fields are in the same direction and so they cannot add up to zero. Throughout interval IV, the electric-field strength due to the positive charge at $x = 1.00$ cm is larger than the electric-field strength due to the negative charge at $x = -1.00$ cm. The fields due to the positive charges at $x = 0$ and $x = 1.00$ cm both point in the $+x$ direction, so the resultant field throughout this interval must also point in the $+x$ direction. Hence we can narrow our search for points on the x axis where the magnitude of the electric field is zero to intervals I and III. Setting the resultant electric-field strength on the x axis equal to zero throughout these intervals and solving the resulting quadratic equations will identify the desired points. Sketching the electric field vectors in intervals I and III will help you get the signs of the terms in the quadratic equations right.



Using Coulomb's law, and letting r_{11}, r_{21}, and r_{31} represent the distances from P_1 to point charges q_1, q_2, and q_3, respectively, express the electric field at P_1 due to the three charges:

$$\vec{E}_{P_1} = \vec{E}_{q_1} + \vec{E}_{q_2} + \vec{E}_{q_3} = \frac{kq_1}{r_{11}^2}\hat{i} + \frac{kq_2}{r_{21}^2}\hat{i} + \frac{kq_3}{r_{31}^2}\hat{i} = k\left[\frac{q_1}{r_{11}^2} + \frac{q_2}{r_{21}^2} + \frac{q_3}{r_{31}^2}\right]\hat{i}$$

Substitute numerical values and evaluate $\vec{E}_{P_1}$:

$$\vec{E}_{P_1} = \left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\left[\frac{-5.00\,\mu\text{C}}{(4.00\,\text{cm})^2} + \frac{3.00\,\mu\text{C}}{(3.00\,\text{cm})^2} + \frac{5.00\,\mu\text{C}}{(2.00\,\text{cm})^2}\right]\hat{i} = \boxed{\left(1.14\times10^8\ \text{N/C}\right)\hat{i}}$$

Using Coulomb's law, and letting r_{12}, r_{22}, and x_{32} represent the distances from P_2 to point charges q_1, q_2, and q_3, respectively, express the electric field at P_2 due to the three charges:

$$\vec{E}_{P_2} = \vec{E}_{q_1} + \vec{E}_{q_2} + \vec{E}_{q_3} = k\left[\frac{q_1}{r_{12}^2} + \frac{q_2}{r_{22}^2} + \frac{q_3}{r_{32}^2}\right]\hat{i}$$

Substitute numerical values and evaluate $\vec{E}_{P_2}$:

$$\vec{E}_{P_2} = \left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\left[\frac{-5.00\,\mu\text{C}}{(16.0\,\text{cm})^2} + \frac{3.00\,\mu\text{C}}{(15.0\,\text{cm})^2} + \frac{5.00\,\mu\text{C}}{(14.0\,\text{cm})^2}\right]\hat{i} = \boxed{\left(1.74\times10^6\ \text{N/C}\right)\hat{i}}$$

Applying Coulomb's law for electric fields and the superposition of fields in interval I yields:

$$\frac{5.00\,\mu\text{C}}{[x-(-1.00\,\text{cm})]^2}-\frac{3.00\,\mu\text{C}}{x^2}-\frac{5.00\,\mu\text{C}}{(x-1.00\,\text{cm})^2}=0$$

where k has been divided out and x is in the interval defined by $x < 0$. The root of this equation that is in the interval $x < -1.00$ cm is $\boldsymbol{x} = \boxed{-6.95\,\text{cm}}$.

Applying Coulomb's law for electric fields and the superposition of fields in interval III yields:

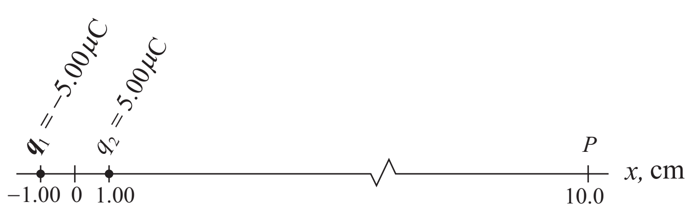
$$-\frac{5.00\,\mu\text{C}}{[x-(-1.00\,\text{cm})]^2}+\frac{3.00\,\mu\text{C}}{x^2}-\frac{5.00\,\mu\text{C}}{(1.00\,\text{cm}-x)^2}=0$$

The root of this equation that is in the interval $0 < x < 1.00$ cm is $x = \boxed{0.417\,\text{cm}}$

63 •• Point charges of $-5.00\ \mu$C and $+5.00\ \mu$C are located on the x axis at $x = -1.00$ cm and $x = +1.00$ cm, respectively. (*a*) Calculate the electric field strength at $x = 10.0$ cm. (*b*) Estimate the electric field strength at $x = 10.00$ cm by modeling the two charges as an electric dipole located at the origin and using $E = 2kp/|x|^3$ (Equation 21-10). Compare your result with the result obtained in Part (*a*), and explain the reason for the difference between the two results.

Comment: David: In 88 notice the many changes.

Picture the Problem Let the point of interest ($x = 10.0$ cm) be identified as point P. In Part (*a*) we can use Coulomb's law for $\vec{E}$ due to a point charge and the superposition principle to find the electric field strength at P. In Part (*b*) we can use Equation 21-10 with $p = 2aq$ to estimate the electric field strength at P.



(*a*) Express the electric field at P as the sum of the fields due to the point charges located at $x = -1.00$ cm and $x = 1.00$ cm:

$$\vec{E}_P = \vec{E}_{q_1} + \vec{E}_{q_2} = \frac{kq_1}{x^2_{-1.00\,\text{cm}\to P}}\hat{i} + \frac{kq_2}{x^2_{1.00\,\text{cm}\to P}}\hat{i} = k\left[\frac{q_1}{x^2_{-1.00\,\text{cm}\to P}} + \frac{q_2}{x^2_{1.00\,\text{cm}\to P}}\right]\hat{i}$$

Substitute numerical values and evaluate $\vec{E}_P$:

$$\vec{E}_P = \left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left[\frac{-5.00\ \mu\text{C}}{(11.00\ \text{cm})^2} + \frac{5.00\ \mu\text{C}}{(9.00\ \text{cm})^2}\right]\hat{i} = \left(1.83\times10^6\ \text{N/C}\right)\hat{i}$$

and

$$E_P = \boxed{1.83\times10^6\ \text{N/C}}$$

(*b*) The electric field strength due to a dipole is given by Equation 21-10:

$$E = \frac{2kp}{|x|^3}$$

Because $p = 2qa$, where $2a$ is the separation of the charges that constitute the dipole, E is also given by:

$$E = \frac{4kqa}{|x|^3}$$

Substitute numerical values and evaluate E_P:

$$E_P = \frac{4\left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(5.00\ \mu\text{C})(1.00\ \text{cm})}{|10.0\ \text{cm}|^3} = \boxed{1.80\times10^6\ \text{N/C}}$$

The exact and estimated values of E_P agree to within 2%. This difference is due to the fact that the separation of the two charges of the dipole is 20% of the distance from the center of the dipole to point P.

64 •• A fixed point charge of $+2q$ is connected by strings to point charges of $+q$ and $+4q$, as shown in Figure 21-41. Find the tensions T_1 and T_2.

Picture the Problem The electrostatic forces between the charges are responsible for the tensions in the strings. We'll assume that these are point charges and apply Coulomb's law and the principle of the superposition of forces to find the tension in each string.

Use Coulomb's law to express the net force on the charge $+q$:

$$T_1 = F_{2q} + F_{4q}$$

Substitute and simplify to obtain:

$$T_1 = \frac{kq(2q)}{d^2} + \frac{kq(4q)}{(2d)^2} = \boxed{\frac{3kq^2}{d^2}}$$

Use Coulomb's law to express the net force on the charge $+4q$:

$$T_2 = F_q + F_{2q}$$

Substitute and simplify to obtain:

$$T_2 = \frac{k(2q)(4q)}{d^2} + \frac{kq(4q)}{(2d)^2} = \boxed{\frac{9kq^2}{d^2}}$$

65 •• [SSM] A positive charge Q is to be divided into two positive point charges q_1 and q_2. Show that, for a given separation D, the force exerted by one charge on the other is greatest if $q_1 = q_2 = \frac{1}{2}Q$.

Picture the Problem We can use Coulomb's law to express the force exerted on one charge by the other and then set the derivative of this expression equal to zero to find the distribution of the charge that maximizes this force.

Using Coulomb's law, express the force that either charge exerts on the other:

$$F = \frac{kq_1q_2}{D^2}$$

Express q_2 in terms of Q and q_1:

$$q_2 = Q - q_1$$

Substitute for q_2 to obtain:

$$F = \frac{kq_1(Q - q_1)}{D^2}$$

Differentiate F with respect to q_1 and set this derivative equal to zero for extreme values:

$$\frac{dF}{dq_1} = \frac{k}{D^2}\frac{d}{dq_1}\left[q_1(Q - q_1)\right]$$
$$= \frac{k}{D^2}\left[q_1(-1) + Q - q_1\right]$$
$$= 0 \text{ for extrema}$$

Solve for q_1 to obtain:

$$q_1 = \tfrac{1}{2}Q \Rightarrow q_2 = Q - q_1 = \tfrac{1}{2}Q$$

To determine whether a maximum or a minimum exists at $q_1 = \frac{1}{2}Q$, differentiate F a second time and evaluate this derivative at $q_1 = \frac{1}{2}Q$:

$$\frac{d^2F}{dq_1^2} = \frac{k}{D^2}\frac{d}{dq_1}[Q - 2q_1]$$
$$= \frac{k}{D^2}(-2)$$
$$< 0 \text{ independently of } q_1.$$
$$\boxed{\therefore q_1 = q_2 = \tfrac{1}{2}Q \text{ maximizes } F.}$$

66 •• A point charge Q is located on the x axis at $x = 0$, and a point charge $4Q$ is located at $x = 12.0$ cm. The electric force on a point charge of $-2.00\ \mu\text{C}$ is zero if that charge is placed at $x = 4.00$ cm, and is 126 N in the $+x$ direction if placed at $x = 8.00$ cm. Determine the charge Q.

Picture the Problem We can apply Coulomb's law and the superposition of forces to relate the net force acting on the charge $q = -2.00\ \mu\text{C}$ to x. Because Q divides out of our equation when $F(x) = 0$, we'll substitute the data given for $x = 8.00$ cm.

Using Coulomb's law, express the net electric force on q as a function of x:

$$F(x) = -\frac{kqQ}{x^2} + \frac{kq(4Q)}{(12.0\,\text{cm} - x)^2}$$

Solving for Q yields:

$$Q = \frac{F(x)}{kq\left[-\dfrac{1}{x^2} + \dfrac{4}{(12.0\,\text{cm} - x)^2}\right]}$$

Evaluate Q for $x = 8.00$ cm:

$$Q = \frac{126\,\text{N}}{(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2.00\,\mu\text{C})\left[-\dfrac{1}{(8.00\,\text{cm})^2} + \dfrac{4}{(4.00\,\text{cm})^2}\right]} = \boxed{2.99\,\mu\text{C}}$$

67 •• Two point particles separated by 0.60 m carry a total charge of 200 μC. (*a*) If the two particles repel each other with a force of 80 N, what is the charge on each of the two particles? (*b*) If the two particles attract each other with a force of 80 N, what are the charges on the two particles?

Picture the Problem Knowing the total charge of the two point particles, we can use Coulomb's law to find the two combinations of charge that will satisfy the condition that both are positive and hence repel each other. If the particles attract each other, then there is just one distribution of charge that will satisfy the conditions that the force is attractive and the sum of the two charges is 200 μC.

(*a*) Use Coulomb's law to express the repulsive electric force each particle exerts on the other:

$$F = \frac{kq_1q_2}{r_{1,2}^2}$$

Express q_2 in terms of the total charge and q_1:

$$q_2 = Q - q_1$$

Substitute for q_2 to obtain:

$$F = \frac{kq_1(Q-q_1)}{r_{1,2}^2} = \frac{k(Qq_1 - q_1^2)}{r_{1,2}^2}$$

Writing this equation explicitly as a quadratic equation gives:

$$q_1^2 - Qq_1 + \frac{Fr_{1,2}^2}{k} = 0$$

Substitute numerical values to obtain:

$$q_1^2 - (200\,\mu\text{C})q_1 + \frac{(80\,\text{N})(0.60\,\text{m})^2}{8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = 0$$

or

$$q_1^2 - \left(2.00\times10^{-4}\,\text{C}\right)q_1 + 3.20\times10^{-9}\,\text{C}^2 = 0$$

Use the quadratic formula or your graphing calculator to obtain:

$$q_1 = \boxed{1.8\times10^{-5}\ \text{C}}$$

and

$$q_2 = Q - q_1 = \boxed{1.8\times10^{-4}\ \text{C}}$$

(*b*) Use Coulomb's law to express the attractive electric force each particle exerts on the other:

$$F = -\frac{kq_1q_2}{r_{1,2}^2}$$

Proceed as in (*a*) to obtain:

$$q_1^2 - \left(2.00\times10^{-4}\,\text{C}\right)q_1 - 3.20\times10^{-9}\,\text{C}^2 = 0$$

Solve this quadratic equation to obtain:

$$q_1 = \boxed{-1.5\times10^{-5}\ \text{C}}$$

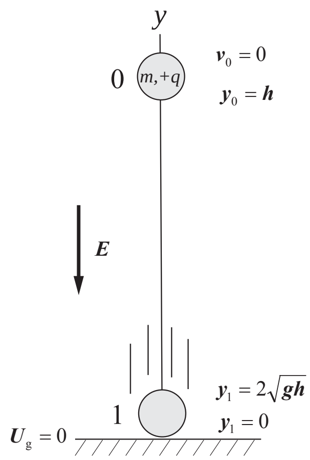
and

$$q_2 = Q - q_1 = \boxed{2.1\times10^{-4}\ \text{C}}$$

68 •• A point particle that has charge $+q$ and unknown mass m is released from rest in a region that has a uniform electric field $\vec{E}$ that is directed vertically

downward. The particle hits the ground at a speed $v = 2\sqrt{gh}$, where h is the initial height of the particle. Find m in terms of E, q, and g.

Picture the Problem Choose the coordinate system shown in the diagram and let $U_g = 0$ where $y = 0$. We'll let our system include the point particle and Earth. Then the work done on the point particle by the electric field will change the energy of the system. The diagram summarizes what we know about the motion of the point particle. We can apply the work-energy theorem to our system to relate the work done by the electric field to the change in its energy.



Using the work-energy theorem, relate the work done by the electric field to the change in the energy of the system:

$$W_{\substack{\text{electric}\\\text{field}}} = \Delta K + \Delta U_g$$

$$= K_1 - K_0 + U_{g,1} - U_{g,0}$$

or, because $K_1 = U_{g,1} = 0$,

$$W_{\substack{\text{electric}\\\text{field}}} = K_1 - U_{g,1}$$

Substitute for $W_{\substack{\text{electric}\\\text{field}}}$, K_1 and $U_{g,1}$ and simplify to obtain:

$$qEh = \tfrac{1}{2}mv_1^2 - mgh$$

$$= \tfrac{1}{2}m\left(2\sqrt{gh}\right)^2 - mgh = mgh$$

Solving for m yields:

$$m = \boxed{\frac{qE}{g}}$$

69 •• [SSM] A rigid 1.00-m-long rod is pivoted about its center (Figure 21-42). A charge $q_1 = 5.00 \times 10^{-7}$ C is placed on one end of the rod, and a charge $q_2 = -q_1$ is placed a distance $d = 10.0$ cm directly below it. (*a*) What is the force exerted by q_2 on q_1? (*b*) What is the torque (measured about the rotation axis) due to that force? (*c*) To counterbalance the attraction between the two charges, we hang a block 25.0 cm from the pivot as shown. What value should we choose for the mass of the block? (*d*) We now move the block and hang it a distance of 25.0 cm from the balance point, on the same side of the balance as the charge. Keeping q_1 the same, and d the same, what value should we choose for q_2 to keep this apparatus in balance?

Picture the Problem We can use Coulomb's law, the definition of torque, and the condition for rotational equilibrium to find the electrostatic force between the two charged bodies, the torque this force produces about an axis through the center of the rod, and the mass required to maintain equilibrium when it is located either 25.0 cm to the right or to the left of the mid-point of the rod.

(*a*) Using Coulomb's law, express the electric force between the two charges:

$$F = \frac{kq_1q_2}{d^2}$$

Substitute numerical values and evaluate F:

$$F = \frac{\left(8.988\times10^9\ \mathrm{N\cdot m^2/C^2}\right)\left(5.00\times10^{-7}\ \mathrm{C}\right)^2}{\left(0.100\ \mathrm{m}\right)^2} = 0.2247\ \mathrm{N} = \boxed{0.225\ \mathrm{N}}\text{, downward}$$

(*b*) The torque (measured about the rotation axis) due to the force F is:

$$\tau = F\ell$$

Substitute numerical values and evaluate τ:

$$\tau = \left(0.2247\ \mathrm{N}\right)\left(0.500\ \mathrm{m}\right) = 0.1124\ \mathrm{N\cdot m} = \boxed{0.112\ \mathrm{N\cdot m}},$$

counterclockwise.

(*c*) Apply $\sum\tau_{\substack{\text{center of}\\ \text{the rod}}} = 0$ to the rod:

$$\tau - mg\ell' = 0 \Rightarrow m = \frac{\tau}{g\ell'}$$

Substitute numerical values and evaluate m:

$$m = \frac{0.1124\ \mathrm{N\cdot m}}{\left(9.81\ \mathrm{m/s^2}\right)\left(0.250\ \mathrm{m}\right)} = 0.04583\ \mathrm{kg} = \boxed{45.8\ \mathrm{g}}$$

(*d*) Apply $\sum\tau_{\substack{\text{center of}\\ \text{the rod}}} = 0$ to the rod:

$$-\tau + mg\ell' = 0$$

Substitute for τ to obtain:

$$-F\ell + mg\ell' = 0$$

Substituting for F gives:

$$-\frac{kq_1q_2'}{d^2} + mg\ell' = 0 \Rightarrow q_2' = \frac{d^2mg\ell'}{kq_1\ell}$$

where q' is the required charge.

Substitute numerical values and evaluate q_2':

$$q_2' = \frac{\left(0.100\ \mathrm{m}\right)^2\left(0.04582\ \mathrm{kg}\right)\left(9.81\ \mathrm{m/s^2}\right)\left(0.250\ \mathrm{m}\right)}{\left(8.988\times10^9\ \mathrm{N\cdot m^2/C^2}\right)\left(5.00\times10^{-7}\ \mathrm{C}\right)\left(0.500\ \mathrm{m}\right)} = \boxed{5.00\times10^{-7}\ \mathrm{C}}$$

70 •• Two 3.0-μC point charges are located at $x = 0$, $y = 2.0$ m and at $x = 0$, $y = -2.0$ m. Two other point charges, each with charge equal to Q, are located at $x = 4.0$ m, $y = 2.0$ m and at $x = 4.0$ m, $y = -2.0$ m (Figure 21-43). The electric field at $x = 0$, $y = 0$ due to the presence of the four charges is $(4.0 \times 10^3\ \text{N/C})\hat{\boldsymbol{i}}$. Determine Q.

Picture the Problem The field at (0, 0) produced by the two 3.0 μC charges is zero. Thus the entire field at (0, 0) is due to the two point charges whose charges are Q. Let the numeral 1 refer to the point charge in the 1st quadrant and the numeral 2 to the point charge in the 4th quadrant. We can use Coulomb's law for the electric field due to a point charge and the superposition of forces to express the field at the origin and use this equation to solve for Q.

Express the electric field at the origin due to the point charges Q:

$$\begin{aligned}\vec{\boldsymbol{E}}(0,0) &= \vec{\boldsymbol{E}}_1 + \vec{\boldsymbol{E}}_2 = \frac{kQ}{r_{1,0}^2}\hat{\boldsymbol{r}}_{1,0} + \frac{kQ}{r_{2,0}^2}\hat{\boldsymbol{r}}_{2,0} \\ &= \frac{kQ}{r^3}\left[(-4.0\,\text{m})\hat{\boldsymbol{i}} + (-2.0\,\text{m})\hat{\boldsymbol{j}}\right] + \frac{kQ}{r^3}\left[(-4.0\,\text{m})\hat{\boldsymbol{i}} + (2.0\,\text{m})\hat{\boldsymbol{j}}\right] = -\frac{(8.0\,\text{m})kQ}{r^3}\hat{\boldsymbol{i}} \\ &= E_x\hat{\boldsymbol{i}}\end{aligned}$$

where r is the distance from each charge to the origin and $E_x = -\dfrac{(8.0\,\text{m})kQ}{r^3}$.

Express r in terms of the coordinates (x, y) of the point charges:

$$r = \sqrt{x^2 + y^2}$$

Substitute for r to obtain:

$$E_x = -\frac{(8.0\,\text{m})kQ}{\left(x^2 + y^2\right)^{3/2}}$$

Solving for Q yields:

$$Q = -\frac{E_x\left(x^2 + y^2\right)^{3/2}}{k(8.0\,\text{m})}$$

Substitute numerical values and evaluate Q:

$$Q = -\frac{(4.0\,\text{kN/C})\left[(4.0\,\text{m})^2 + (2.0\,\text{m})^2\right]^{3/2}}{\left(8.988 \times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(8.0\,\text{m})} = \boxed{-5.0\,\mu\text{C}}$$

71 •• **[SSM]** Two point charges have a total charge of 200 μC and are separated by 0.600 m. (*a*) Find the charge of each particle if the particles repel each other with a force of 120 N. (*b*) Find the force on each particle if the charge on each particle is 100 μC.

Picture the Problem Let the numeral 1 denote one of the point charges and the numeral 2 the other. Knowing the total charge on the two spheres, we can use Coulomb's law to find the charge on each of them. A second application of Coulomb's law when the spheres carry the same charge and are 0.600 m apart will yield the force each exerts on the other.

(*a*) Use Coulomb's law to express the repulsive force each point charge exerts on the other:

$$F = \frac{kq_1q_2}{r_{1,2}^2}$$

Express q_2 in terms of the total charge and q_1:

$$q_2 = Q - q_1$$

Substitute for q_2 to obtain:

$$F = \frac{kq_1(Q - q_1)}{r_{1,2}^2}$$

Substitute numerical values to obtain:

$$120\,\text{N} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left[(200\,\mu\text{C})q_1 - q_1^2\right]}{(0.600\,\text{m})^2}$$

Simplify to obtain the quadratic equation:

$$q_1^2 + (-200\,\mu\text{C})q_1 + 4806(\mu\text{C})^2 = 0$$

Use the quadratic formula or your graphing calculator to obtain:

$$q_1 = 27.9\,\mu\text{C and } 172\,\mu\text{C}$$

Hence the charges on the particles are:

$$\boxed{27.9\,\mu\text{C}} \text{ and } \boxed{172\,\mu\text{C}}$$

(*b*) Use Coulomb's law to express the repulsive force each point charge exerts on the other when $q_1 = q_2 = 100\ \mu\text{C}$:

$$F = \frac{kq_1q_2}{r_{1,2}^2}$$

Substitute numerical values and evaluate F:

$$F = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(100\,\mu\text{C})^2}{(0.600\,\text{m})^2} = \boxed{250\,\text{N}}$$

72 •• Two point charges have a total charge of 200 μC and are separated by 0.600 m. (*a*) Find the charge of each particle if the particles attract each other with a force of 120 N. (*b*) Find the force on each particle if the charge on each particle is 100 μC.

Picture the Problem Let the numeral 1 denote one of the point charges and the numeral 2 the other. Knowing the total charge on the two point charges, we can use Coulomb's law to find the charge on each of them. A second application of Coulomb's law when the particles carry the same charge and are 0.600 m apart will yield the electric force each exerts on the other.

(*a*) Use Coulomb's law to express the attractive electric force each point charge exerts on the other:

$$F = -\frac{kq_1q_2}{r_{1,2}^2}$$

Express q_2 in terms of the total charge and q_1:

$$q_2 = Q - q_1$$

Substitute for q_2 to obtain:

$$F = -\frac{kq_1(Q - q_1)}{r_{1,2}^2}$$

Writing this explicitly as a quadratic equation gives:

$$q_1^2 - Qq_1 - \frac{r_{1,2}^2 F}{k} = 0$$

Substitute numerical values to obtain:

$$q_1^2 - (200\,\mu\text{C})q_1 - \frac{(0.600\,\text{m})^2(120\,\text{N})}{8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = 0$$

or

$$q_1^2 + (-200\,\mu\text{C})q_1 - 4805(\mu\text{C})^2 = 0$$

Use the quadratic formula or your graphing calculator to obtain:

$$q_1 = \boxed{-21.7\,\mu\text{C}}$$

and

$$q_2 = Q - q_1 = \boxed{222\,\mu\text{C}}$$

(*b*) Use Coulomb's law to express the repulsive electric force each point charge exerts on the other when $q_1 = q_2 = 100\ \mu$C:

$$F = \frac{kq_1q_2}{r_{1,2}^2}$$

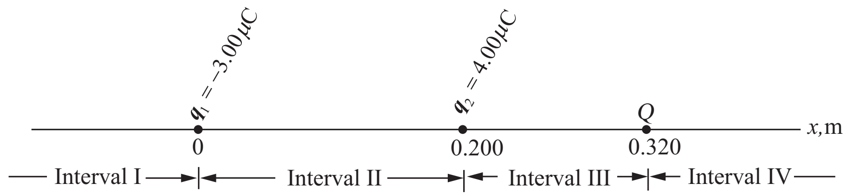
Substitute numerical values and evaluate F:

$$F = \left(8.988\times10^{9}\ \mathrm{N\cdot m^2/C^2}\right)\frac{\left(100\ \mu\mathrm{C}\right)^2}{\left(0.600\ \mathrm{m}\right)^2} = \boxed{250\ \mathrm{N}}$$

73 •• A point charge of –3.00 μC is located at the origin; a point charge of 4.00 μC is located on the x axis at $x = 0.200$ m; a third point charge Q is located on the x axis at $x = 0.320$ m. The electric force on the 4.00-μC charge is 240 N in the $+x$ direction. (a) Determine the charge Q. (b) With this configuration of three charges, at what location(s) is the electric field zero?

Comment: DAVID: In 87 the ism solution is cavilier about the region in which the electric field is zero. Just to say by inspection is little help to those who do not know how to go about the process.

Picture the Problem (a) We can use Coulomb's law for point charges and the superposition of forces to express the net electric force acting on q_2 and then solve this equation to determine the charge Q. (b) To identify the location(s) at which the electric field is zero, we'll need to systematically examine the resultant electric fields in the intervals I, II, III, and IV identified below on the pictorial representation. Drawing the electric field vectors in each of these intervals will help you get the signs of the terms in the field equations right.



(a) Use Coulomb's law to express the electric force on the particle whose charge is 4.00-μC:

$$\vec{F}_2 = \vec{F}_{1,2} + \vec{F}_{Q,2} = \frac{kq_1q_2}{r_{1,2}^2}\hat{i} + \frac{kQq_2}{r_{Q,2}^2}\left(-\hat{i}\right) = kq_2\left[\frac{q_1}{r_{1,2}^2} - \frac{Q}{r_{Q,2}^2}\right]\hat{i} = F_2\hat{i}$$

Solving for Q yields:

$$Q = r_{Q,2}^2\left[\frac{q_1}{r_{1,2}^2} - \frac{F_2}{kq_2}\right]$$

Substitute numerical values and evaluate Q:

$$Q = \left(0.120\ \mathrm{m}\right)^2\left[\frac{-3.00\ \mu\mathrm{C}}{\left(0.200\ \mathrm{m}\right)^2} - \frac{240\ \mathrm{N}}{\left(8.988\times10^{9}\ \mathrm{N\cdot m^2/C^2}\right)\left(4.00\ \mu\mathrm{C}\right)}\right] = \boxed{-97.2\ \mu\mathrm{C}}$$

(*b*) Applying Coulomb's law for electric fields and the superposition of fields in interval I yields:

$$\frac{3.00\ \mu\text{C}}{(x-0)^2}-\frac{4.00\ \mu\text{C}}{(x-0.200\,\text{m})^2}+\frac{97.2\ \mu\text{C}}{(x-0.320\,\text{m})^2}=0$$

where k has been divided out and x is in the interval defined by $x < 0$. The roots of this equation are at x = 0.170 m and x =0.220 m. Neither of these are in interval I.

Applying Coulomb's law for electric fields and the superposition of fields in interval II yields:

$$-\frac{3.00\ \mu\text{C}}{(x-0)^2}-\frac{4.00\ \mu\text{C}}{(x-0.200\,\text{m})^2}+\frac{97.2\ \mu\text{C}}{(x-0.320\,\text{m})^2}=0$$

The roots of this equation are at x = –0.0720 m, x = 0.0508 m, x = 0.169 m, and x = 0.220 m. The second and third of these are in interval II.

Applying Coulomb's law for electric fields and the superposition of fields in interval III yields:

$$-\frac{3.00\ \mu\text{C}}{(x-0)^2}+\frac{4.00\ \mu\text{C}}{(x-0.200\,\text{m})^2}+\frac{97.2\ \mu\text{C}}{(x-0.320\,\text{m})^2}=0$$

The roots of this equation are at x = –0.0649 m and x = 0.0454 m. Neither of these are in interval III.

Applying Coulomb's law for electric fields and the superposition of fields in interval IV yields:

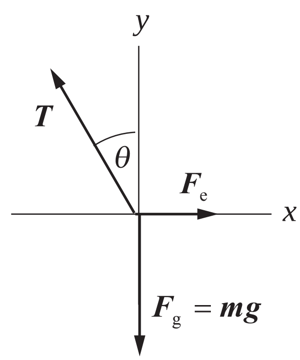
$$-\frac{3.00\ \mu\text{C}}{(x-0)^2}+\frac{4.00\ \mu\text{C}}{(x-0.200\,\text{m})^2}-\frac{97.2\ \mu\text{C}}{(x-0.320\,\text{m})^2}=0$$

The roots of this equation are at x = 0.170 m and x = 0.220. Neither of these are in interval IV.

Summarizing, the electric field is zero at two locations in interval II: $x=\boxed{0.0508\,\text{m}}$ and $x=\boxed{0.169\,\text{m}}$

74 •• Two point particles, each of mass m and charge q, are suspended from a common point by threads of length L. Each thread makes an angle θ with the vertical as shown in Figure 21-44. (*a*) Show that $q=2L\sin\theta\sqrt{(mg/k)\tan\theta}$ where k is the Coulomb constant. (*b*) Find q if m = 10.0 g, L = 50.0 cm, and θ = 10.0º.

Picture the Problem Each point particle is in static equilibrium under the influence of the tension $\vec{T}$, the gravitational force $\vec{F}_g$, and the electric force $\vec{F}_E$. We can use Coulomb's law to relate the electric force to the charge on each particle and their separation and the conditions for static equilibrium to relate these forces to the charge on each particle.



(*a*) Apply the conditions for static equilibrium to the point particle whose free-body diagram is shown above:

$$\sum F_x = F_E - T\sin\theta = \frac{kq^2}{r^2} - T\sin\theta = 0$$

and

$$\sum F_y = T\cos\theta - mg = 0$$

Eliminate T between these equations to obtain:

$$\tan\theta = \frac{kq^2}{mgr^2} \Rightarrow q = r\sqrt{\frac{mg\tan\theta}{k}}$$

Referring to the figure, relate the separation of the spheres r to the length of the pendulum L:

$$r = 2L\sin\theta$$

Substitute for r to obtain:

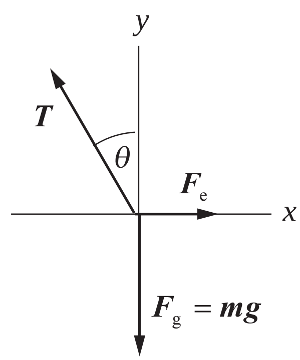
$$q = \boxed{2L\sin\theta\sqrt{\frac{mg\tan\theta}{k}}}$$

(*b*) Evaluate q for m = 10.0 g, L = 50.0 cm, and θ = 10°:

$$q = 2(0.500\,\text{m})\sin 10.0°\sqrt{\frac{(0.0100\,\text{kg})(9.81\,\text{m/s}^2)\tan 10.0°}{8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2}} = \boxed{0.241\,\mu\text{C}}$$

75 •• Suppose that in Problem 74 L = 1.5 m and m = 0.010 kg. (*a*) What is the angle that each string makes with the vertical if q = 0.75 μC? (*b*) What is the angle that each string makes with the vertical if one particle has a charge of 0.50 μC, the other has a charge of 1.0 μC?

Picture the Problem Each sphere is in static equilibrium under the influence of the tension $\vec{T}$, the gravitational force $\vec{F}_g$, and the electric force $\vec{F}_e$. We can use Coulomb's law to relate the electric force to the charge on each sphere and their separation and the conditions for static equilibrium to relate these forces to the charge on each sphere.



(*a*)Apply the conditions for static equilibrium to the charged sphere:

$$\sum F_x = F_e - T\sin\theta = \frac{kq^2}{r^2} - T\sin\theta = 0$$

and

$$\sum F_y = T\cos\theta - mg = 0$$

Eliminate *T* between these equations to obtain:

$$\tan\theta = \frac{kq^2}{mgr^2}$$

Referring to the figure for Problem 74, relate the separation of the spheres *r* to the length of the pendulum *L*:

$$r = 2L\sin\theta$$

Substitute for *r* to obtain:

$$\tan\theta = \frac{kq^2}{4mgL^2\sin^2\theta}$$

or

$$\sin^2\theta\tan\theta = \frac{kq^2}{4mgL^2} \qquad (1)$$

Substitute numerical values and evaluate $\sin^2\theta\tan\theta$:

$$\sin^2\theta\tan\theta = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(0.75\,\mu\text{C}\right)^2}{4\left(0.010\,\text{kg}\right)\left(9.81\,\text{m/s}^2\right)\left(1.5\,\text{m}\right)^2} = 5.73\times10^{-3}$$

Because $\sin^2\theta\tan\theta << 1$:

$$\sin\theta \approx \tan\theta \approx \theta$$

and

$$\theta^3 \approx 5.73\times10^{-3}$$

Solving for θ gives: $\theta = 0.179\,\text{rad} = \boxed{10°}$

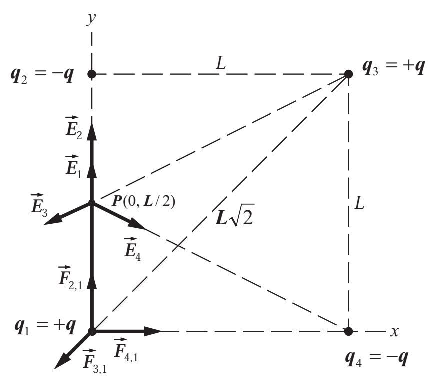
(*b*) Evaluate equation (1) with replacing q^2 with q_1q_2:

$$\sin^2\theta\tan\theta = \frac{(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(0.50\,\mu\text{C})(1.0\,\mu\text{C})}{4(0.010\,\text{kg})(9.81\,\text{m/s}^2)(1.5\,\text{m})^2} = 5.09\times10^{-3} \approx \theta^3$$

Solve for θ to obtain: $\theta = 0.172\,\text{rad} = \boxed{9.9°}$

76 •• Four point charges of equal magnitude are arranged at the corners of a square of side L as shown in Figure 21-45. (*a*) Find the magnitude and direction of the force exerted on the charge in the lower left corner by the other three charges. (*b*) Show that the electric field at the midpoint of one of the sides of the square is directed along that side toward the negative charge and has a magnitude E given by $E = k\dfrac{8q}{L^2}\left(1-\dfrac{1}{5\sqrt{5}}\right)$.

Picture the Problem Let the origin be at the lower left-hand corner and designate the point charges as shown in the diagram. We can apply Coulomb's law for point charges to find the forces exerted on q_1 by q_2, q_3, and q_4 and superimpose these forces to find the net force exerted on q_1. In Part (*b*), we'll use Coulomb's law for the electric field due to a point charge and the superposition of fields to find the electric field at point $P(0, L/2)$.



(*a*) Using superposition of forces, express the net force exerted on q_1:

$$\vec{F}_1 = \vec{F}_{2,1} + \vec{F}_{3,1} + \vec{F}_{4,1}$$

Apply Coulomb's law to express $\vec{F}_{2,1}$:

$$\vec{F}_{2,1} = \frac{kq_2q_1}{r_{2,1}^2}\hat{r}_{2,1} = \frac{kq_2q_1}{r_{2,1}^3}\vec{r}_{2,1} = \frac{k(-q)q}{L^3}\left(-L\,\hat{j}\right) = \frac{kq^2}{L^2}\hat{j}$$

Apply Coulomb's law to express $\vec{F}_{4,1}$:

$$\vec{F}_{4,1}=\frac{kq_4q_1}{r_{4,1}^2}\hat{r}_{4,1}=\frac{kq_4q_1}{r_{4,1}^3}\vec{r}_{4,1}=\frac{k(-q)q}{L^3}\left(-L\,\hat{i}\right)=\frac{kq^2}{L^2}\hat{i}$$

Apply Coulomb's law to express $\vec{F}_{3,1}$:

$$\begin{aligned}\vec{F}_{3,1}&=\frac{kq_3q_1}{r_{3,1}^2}\hat{r}_{3,1}=\frac{kq_3q_1}{r_{3,1}^3}\vec{r}_{3,1}\\&=\frac{kq^2}{2^{3/2}L^3}\left(-L\,\hat{i}-L\,\hat{j}\right)\\&=-\frac{kq^2}{2^{3/2}L^2}\left(\hat{i}+\hat{j}\right)\end{aligned}$$

Substitute and simplify to obtain:

$$\begin{aligned}\vec{F}_1&=\frac{kq^2}{L^2}\hat{j}-\frac{kq^2}{2^{3/2}L^2}\left(\hat{i}+\hat{j}\right)+\frac{kq^2}{L^2}\hat{i}\\&=\frac{kq^2}{L^2}\left(\hat{i}+\hat{j}\right)-\frac{kq^2}{2^{3/2}L^2}\left(\hat{i}+\hat{j}\right)\\&=\boxed{\frac{kq^2}{L^2}\left(1-\frac{1}{2\sqrt{2}}\right)\left(\hat{i}+\hat{j}\right)}\end{aligned}$$

(*b*) Using superposition of fields, express the resultant field at point *P*:

$$\vec{E}_P=\vec{E}_1+\vec{E}_2+\vec{E}_3+\vec{E}_4 \qquad (1)$$

Use Coulomb's law to express $\vec{E}_1$:

$$\begin{aligned}\vec{E}_1&=\frac{kq_1}{r_{1,P}^2}\hat{r}_{1,P}=\frac{kq}{r_{1,P}^3}\left(\frac{L}{2}\hat{j}\right)\\&=\frac{kq}{\left(\frac{L}{2}\right)^3}\left(\frac{L}{2}\hat{j}\right)=\frac{4kq}{L^2}\hat{j}\end{aligned}$$

Use Coulomb's law to express $\vec{E}_2$:

$$\begin{aligned}\vec{E}_2&=\frac{kq_2}{r_{2,P}^2}\hat{r}_{2,P}=\frac{k(-q)}{r_{2,P}^3}\left(\frac{L}{2}\hat{j}\right)\\&=\frac{-kq}{\left(\frac{L}{2}\right)^3}\left(-\frac{L}{2}\hat{j}\right)=\frac{4kq}{L^2}\hat{j}\end{aligned}$$

Use Coulomb's law to express $\vec{E}_3$:

$$\vec{E}_3 = \frac{kq_3}{r_{3,P}^2}\hat{r}_{3,P} = \frac{kq}{r_{3,P}^3}\left(-L\hat{i} - \frac{L}{2}\hat{j}\right)$$
$$= \frac{8kq}{5^{3/2}L^2}\left(-\hat{i} - \frac{1}{2}\hat{j}\right)$$

Use Coulomb's law to express $\vec{E}_4$:

$$\vec{E}_4 = \frac{kq_4}{r_{4,P}^2}\hat{r}_{4,P} = \frac{k(-q)}{r_{4,P}^3}\left(-L\hat{i} + \frac{L}{2}\hat{j}\right)$$
$$= \frac{8kq}{5^{3/2}L^2}\left(\hat{i} - \frac{1}{2}\hat{j}\right)$$

Substitute in equation (1) and simplify to obtain:

$$\vec{E}_P = \frac{4kq}{L^2}\hat{j} + \frac{4kq}{L^2}\hat{j} + \frac{8kq}{5^{3/2}L^2}\left(-\hat{i} - \frac{1}{2}\hat{j}\right) + \frac{8kq}{5^{3/2}L^2}\left(\hat{i} - \frac{1}{2}\hat{j}\right) = \boxed{k\frac{8q}{L^2}\left(1 - \frac{1}{5\sqrt{5}}\right)\hat{j}}$$

77 •• [SSM] Figure 21-46 shows a dumbbell consisting of two identical small particles, each of mass m, attached to the ends of a thin (massless) rod of length a that is pivoted at its center. The particles carry charges of $+q$ and $-q$, and the dumbbell is located in a uniform electric field $\vec{E}$. Show that for small values of the angle θ between the direction of the dipole and the direction of the electric field, the system displays a rotational form of simple harmonic motion, and obtain an expression for the period of that motion.

Picture the Problem We can apply Newton's second law in rotational form to obtain the differential equation of motion of the dipole and then use the small angle approximation $\sin\theta \approx \theta$ to show that the dipole experiences a linear restoring torque and, hence, will experience simple harmonic motion.

Apply $\sum\tau = I\alpha$ to the dipole:

$$-pE\sin\theta = I\frac{d^2\theta}{dt^2}$$

where τ is negative because it acts in such a direction as to decrease θ.

For small values of θ, $\sin\theta \approx \theta$ and:

$$-pE\theta = I\frac{d^2\theta}{dt^2}$$

Express the moment of inertia of the dipole:

$$I = \tfrac{1}{2}ma^2$$

Relate the dipole moment of the dipole to its charge and the charge separation:

$$p = qa$$

Substitute for p and I to obtain:

$$\tfrac{1}{2}ma^2\frac{d^2\theta}{dt^2} = -qaE\theta$$

or

$$\boxed{\frac{d^2\theta}{dt^2} = -\frac{2qE}{ma}\theta}$$

the differential equation for a simple harmonic oscillator with angular frequency $\omega = \sqrt{2qE/ma}$.

Express the period of a simple harmonic oscillator:

$$T = \frac{2\pi}{\omega}$$

Substitute for ω and simplify to obtain:

$$T = \boxed{2\pi\sqrt{\frac{ma}{2qE}}}$$

78 •• For the dumbbell in Problem 77, let m = 0.0200 kg, a = 0.300 m, and $\vec{E} = (600\text{ N/C})\hat{i}$. The dumbbell is initially at rest and makes an angle of 60º with the x axis. The dumbbell is then released, and when it is momentarily aligned with the electric field, its kinetic energy is 5.00 × 10^{-3} J. Determine the magnitude of q.

Picture the Problem We can apply conservation of energy and the definition of the potential energy of a dipole in an electric field to relate q to the kinetic energy of the dumbbell when it is aligned with the field.

Using conservation of energy, relate the initial potential energy of the dumbbell to its kinetic energy when it is momentarily aligned with the electric field:

$$\Delta K + \Delta U = 0$$

or, because $K_i = 0$,

$$K + \Delta U = 0 \qquad (1)$$

where K is the kinetic energy when it is aligned with the field.

Express the change in the potential energy of the dumbbell as it aligns with the electric field in terms of its dipole moment, the electric field, and the angle through which it rotates:

$$\begin{aligned}\Delta U &= U_{\mathrm{f}} - U_{\mathrm{i}} \\ &= -pE\cos\theta_{\mathrm{f}} + pE\cos\theta_{\mathrm{i}} \\ &= qaE(\cos 60° - 1)\end{aligned}$$

Substitute for ΔU in equation (1) to obtain:

$$K + qaE(\cos 60° - 1) = 0$$

Solving for q yields:

$$q = \frac{K}{aE(1 - \cos 60°)}$$

Substitute numerical values and evaluate q:

$$q = \frac{5.00\times10^{-3}\ \mathrm{J}}{(0.300\,\mathrm{m})(600\,\mathrm{N/C})(1-\cos 60°)} = \boxed{56\,\mu\mathrm{C}}$$

79 •• [SSM] An electron (charge $-e$, mass m) and a positron (charge $+e$, mass m) revolve around their common center of mass under the influence of their attractive coulomb force. Find the speed v of each particle in terms of e, m, k, and their separation distance L.

Picture the Problem The forces the electron and the proton exert on each other constitute an action-and-reaction pair. Because the magnitudes of their charges are equal and their masses are the same, we find the speed of each particle by finding the speed of either one. We'll apply Coulomb's force law for point charges and Newton's second law to relate v to e, m, k, and their separation distance L.

Apply Newton's second law to the positron to obtain:

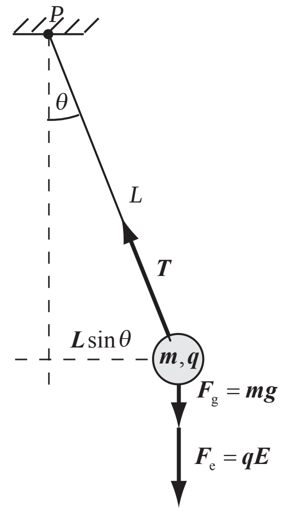
$$\frac{ke^2}{L^2} = m\frac{v^2}{\frac{1}{2}L} \Rightarrow \frac{ke^2}{L} = 2mv^2$$

Solving for v gives:

$$v = \boxed{\sqrt{\frac{ke^2}{2mL}}}$$

80 ••• A simple pendulum of length 1.0 m and mass 5.0×10^{-3} kg is placed in a uniform electric field $\vec{E}$ that is directed vertically upward. The bob has a charge of $-8.0\ \mu$C. The period of the pendulum is 1.2 s. What is the magnitude and direction of $\vec{E}$?

Picture the Problem Because the period of this pendulum is 60% of the period (2.006 s) of a simple pendulum with an uncharged bob, we know that the bob must be experiencing an additional downward force (in the direction of the gravitational force). Because the electric force acting on the negatively-charged bob is downward, the electric field must be upward. We can find the magnitude of the electric field by apply Newton's second law in rotational form to the simple pendulum. Doing so will lead us to the equation of motion for the pendulum and from this equation we can obtain an expression relating its period to the magnitude of E. Knowing the pendulum's period in the absence of the electric field will allow us to derive an expression for E from the ratio of the two periods.



Taking clockwise torques to be negative, apply $\sum \tau_P = I_P\alpha$ to the pendulum bob to obtain:

$$-(mg+qE)L\sin\theta = I_P\alpha$$

or, because $I_P = mL^2$ and $\alpha = \dfrac{d^2\theta}{dt^2}$,

$$-(mg+qE)L\sin\theta = mL^2\frac{d^2\theta}{dt^2}$$

For small displacements from equilibrium, $\sin\boldsymbol{\theta} \approx \boldsymbol{\theta}$:

$$mL^2\frac{d^2\theta}{dt^2} = -(mg+qE)L\theta$$

or

$$\frac{d^2\theta}{dt^2} + \frac{mg+qE}{mL}\theta = 0$$

This is the equation of simple harmonic motion with:

$$\omega^2 = \frac{mg+qE}{mL}$$

The period of this motion is given by:

$$T' = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{mL}{mg+qE}}$$

In the absence of the electric field, the period of the simple pendulum would be:

$$T = 2\pi\sqrt{\frac{L}{g}}$$

Dividing the second of these equations by the first and simplifying yields:

$$\frac{T}{T'}=\frac{2\pi\sqrt{\frac{L}{g}}}{2\pi\sqrt{\frac{mL}{mg+qE}}}=\sqrt{\frac{mg+qE}{mg}}$$
$$=\sqrt{1+\frac{qE}{mg}}$$

Solving for E gives:

$$E=\frac{mg}{q}\left[\left(\frac{T}{T'}\right)-1\right]$$

Noting that the period of the simple pendulum in the absence of the electric field is 2.006 s, substitute numerical values and evaluate E:

$$E=\frac{(5.0\text{ mg})(9.81\text{ m/s}^2)}{8.0\ \mu\text{C}}\left[\left(\frac{2.006\text{ s}}{1.2\text{ s}}\right)^2-1\right]=\boxed{1.1\times10^4\text{ N/C}}\text{, upward}$$

81 ••• A point particle of mass m and charge q is constrained to move vertically inside a narrow, frictionless cylinder (Figure 21-47). At the bottom of the cylinder is a point charge Q having the same sign as q. (a) Show that the particle whose mass is m will be in equilibrium at a height $y_0 = (kqQ/mg)^{1/2}$. (b) Show that if the particle is displaced from its equilibrium position by a small amount and released, it will exhibit simple harmonic motion with angular frequency $\omega = (2g/y_0)^{1/2}$.

Picture the Problem We can use Coulomb's force law for point particles and the condition for translational equilibrium to express the equilibrium position as a function of k, q, Q, m, and g. In Part (b) we'll need to show that the displaced point charge experiences a linear restoring force and, hence, will exhibit simple harmonic motion.

(a) Apply the condition for translational equilibrium to the particle:

$$\frac{kqQ}{y_0^2}-mg=0\Rightarrow y_0=\boxed{\sqrt{\frac{kqQ}{mg}}}$$

(b) Express the restoring force that acts on the particle when it is displaced a distance Δy from its equilibrium position:

$$F=\frac{kqQ}{(y_0+\Delta y)^2}-\frac{kqQ}{y_0^2}$$

or, because $\Delta y \ll y_0$,

$$F\approx\frac{kqQ}{y_0^2+2y_0\Delta y}-\frac{kqQ}{y_0^2}$$

Simplify this expression further by writing it with a common denominator:

$$F=-\frac{2y_0\Delta ykqQ}{y_0^4+2y_0^3\Delta y}=-\frac{2y_0\Delta ykqQ}{y_0^4\left(1+2\dfrac{\Delta y}{y_0}\right)}\approx-\frac{2\Delta ykqQ}{y_0^3}$$

again, because $\Delta y << y_0$.

From the 1st step of our solution: $\dfrac{kqQ}{y_0^2}=mg$

Substitute for $\dfrac{kqQ}{y_0^2}$ and simplify to obtain: $F=-\dfrac{2mg}{y_0}\Delta y$

Apply Newton's second law to the displaced particle to obtain:

$$m\frac{d^2\Delta y}{dt^2}=-\frac{2mg}{y_0}\Delta y$$

or

$$\boxed{\frac{d^2\Delta y}{dt^2}+\frac{2g}{y_0}\Delta y=0}$$

the differential equation of simple harmonic motion with $\omega=\boxed{\sqrt{2g/y_0}}$.

82 ••• Two neutral molecules on the x axis attract each other. Each molecule has a dipole moment $\vec{p}$, and these dipole moments are on the $+x$ axis and are separated by a distance d. Derive an expression for the force of attraction in terms of p and d.

Picture the Problem We can relate the force of attraction that each molecule exerts on the other to the potential energy function of either molecule using $F=-dU/dx$. We can relate U to the electric field at either molecule due to the presence of the other through $U = -pE$. Finally, the electric field at either molecule is given by $E=2kp/x^3$.

Express the force of attraction between the dipoles in terms of the spatial derivative of the potential energy function of p_1:

$$F=-\frac{dU_1}{dx} \qquad (1)$$

Express the potential energy of the dipole p_1:

$U_1=-p_1E_1$

where E_1 is the field at p_1 due to p_2.

Express the electric field strength at p_1 due to p_2:

$$E_1 = \frac{2kp_2}{x^3}$$

where x is the separation of the dipoles.

Substitute for E_1 to obtain:

$$U_1 = -\frac{2kp_1p_2}{x^3}$$

Substitute in equation (1) and differentiate with respect to x:

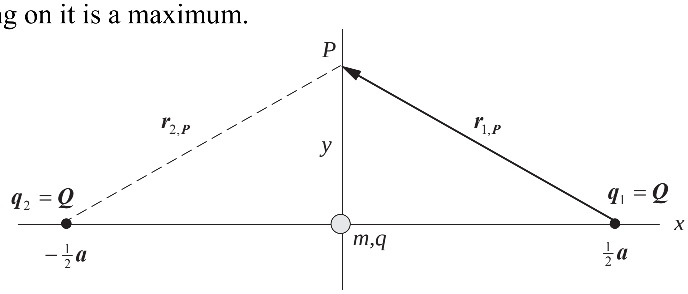
$$F = -\frac{d}{dx}\left[-\frac{2kp_1p_2}{x^3}\right] = \frac{6kp_1p_2}{x^4}$$

Evaluate F for $p_1 = p_2 = p$ and $x = d$ to obtain:

$$F = \boxed{\frac{6kp^2}{d^4}}$$

83 ••• Two equal positive point charges Q are on the x axis at $x = \frac{1}{2}a$ and $x = -\frac{1}{2}a$. (*a*) Obtain an expression for the electric field on the y axis as a function of y. (*b*) A bead of mass M, which has a charge q, moves along the y axis on a thin frictionless taut thread. Find the electric force that acts on the bead as a function of y and determine the sign of q such that this force always points away from the origin. (*c*) The bead is initially at rest at the origin. If it is given a slight nudge in the $+y$ direction, how fast will the bead be traveling the instant the net force on it is a maximum? (Assume any effects due to gravity are negligible.)

Picture the Problem (*a*) We can use Coulomb's law for the electric field due to a point charge and superposition of fields to find the electric field at any point on the y axis. (*b*) Using the definition of electric field will yield an expression for the electric force that acts on the bead. In Part (*c*) we can set $dF_y/dy = 0$ to find the value of y that maximizes F_y and then use the work-kinetic energy theorem (integrating F_y from 0 to this extreme value will yield an expression for the work done on the bead during this displacement) to find the speed of the bead when the force acting on it is a maximum.



(*a*) Use Coulomb's law for the electric field due to a point charge and superposition of fields, to express the field at point P on the y axis:

$$\vec{E}_y = \vec{E}_1 + \vec{E}_2 = \frac{kq_1}{r_{1,P}^2}\hat{r}_{1,P} + \frac{kq_2}{r_{2,P}^2}\hat{r}_{2,P}$$

The unit vectors $\hat{r}_{1,P}$ and $\hat{r}_{2,P}$ are given by:

$$\hat{r}_{1,P} = \frac{\hat{r}_{1,P}}{r_{1,P}} = \frac{-\frac{1}{2}a\hat{i} + y\hat{j}}{r_{1,P}}$$

and

$$\hat{r}_{2,P} = \frac{\hat{r}_{2,P}}{r_{2,P}} = \frac{\frac{1}{2}a\hat{i} + y\hat{j}}{r_{2,P}}$$

Substituting for q_1, q_2, $\hat{r}_{1,P}$, $\hat{r}_{2,P}$ and $r_{1,P} = r_{2,\mathrm{P}} = \left[y^2 + \left(\frac{1}{2}a\right)^2\right]^{1/2}$ yields:

$$\vec{E}_y = \frac{kQ}{r_{1,P}^2}\left(\frac{-\frac{1}{2}a\hat{i} + y\hat{j}}{r_{1,P}}\right) + \frac{kQ}{r_{2,P}^2}\left(\frac{\frac{1}{2}a\hat{i} + y\hat{j}}{r_{2,P}}\right) = \frac{kQ}{r_{1,P}^3}\left(-\frac{1}{2}a\hat{i} + y\hat{j}\right) + \frac{kQ}{r_{2,P}^3}\left(\frac{1}{2}a\hat{i} + y\hat{j}\right)$$

$$= \frac{kQ}{\left[y^2 + \left(\frac{1}{2}a\right)^2\right]^{3/2}}\left(y\hat{j}\right) + \frac{kQ}{\left[y^2 + \left(\frac{1}{2}a\right)^2\right]^{3/2}}\left(y\hat{j}\right) = \boxed{\frac{2kQy}{\left[y^2 + \frac{1}{4}a^2\right]^{3/2}}\hat{j}}$$

(*b*) Relate the electric force on the bead to its charge and the electric field:

$$\vec{F} = q\vec{E}_y = \boxed{\frac{2kqQy}{\left[y^2 + \frac{1}{4}a^2\right]^{3/2}}\hat{j}}$$

where q must be positive if $\vec{F}$ always points away from the origin.

(*c*) Apply the work-kinetic energy theorem to the bead as it moves from the origin to the location at which F_y is a maximum to obtain:

$$W_{\mathrm{net}_y} = \Delta K = K_\mathrm{f} - K_\mathrm{i}$$

or, because $K_\mathrm{i} = 0$,

$$W_{\text{done by } F_y} = \frac{1}{2}Mv_\mathrm{f}^2$$

Solving for v_f yields:

$$v_\mathrm{f} = \sqrt{\frac{2W_{\text{done by } F_y}}{M}}$$

The work done on the bead by F_y as the bead moves from the origin to $y_{\max}$ (the y coordinate of the point at which F_y is a maximum) is given by:

$$W_{\text{done by } F_y} = \int_0^{y_{\max}} \frac{2kqQy}{\left[y^2 + \left(\frac{1}{2}a\right)^2\right]^{3/2}}dy$$

Substituting for $W_{\text{done by } F_y}$ and simplifying yields:

$$v_f = \sqrt{\frac{4kqQ}{m}\int_0^{y_{max}} \frac{y}{\left[y^2 + \left(\frac{1}{2}a\right)^2\right]^{3/2}}dy}$$

The condition that F_y is a maximum is:

$$\frac{dF_y}{dy} = \frac{d}{dy}\left[\frac{y}{\left[y^2 + \left(\frac{1}{2}a\right)^2\right]^{3/2}}\right] = 0$$

Carrying out the details of the differentiation and solving for the critical value y_{max} yields:

$y_{max} = \dfrac{a}{2\sqrt{2}}$ where we've ignored the negative value because the bead is given a nudge in the $+y$ direction.

Substitute for y_{max} in the expression for v_f to obtain:

$$v_f = \sqrt{\frac{4kqQ}{M}\int_0^{\frac{a}{2\sqrt{2}}} \frac{y}{\left[y^2 + \left(\frac{1}{2}a\right)^2\right]^{3/2}}dy}$$

Evaluating the integral yields:

$$\int_0^{\frac{a}{2\sqrt{2}}} \frac{y}{\left[y^2 + \left(\frac{1}{2}a\right)^2\right]^{3/2}}dy \approx \frac{0.367}{a}$$

Substitute for $\int_0^{\frac{a}{2\sqrt{2}}} \frac{y}{\left[y^2 + \left(\frac{1}{2}a\right)^2\right]^{3/2}}dy$ and simplify to obtain:

$$v_f = \sqrt{\frac{4kqQ}{M}\left(\frac{0.367}{a}\right)} = \boxed{1.21\sqrt{\frac{kqQ}{aM}}}$$

84 ••• A gold nucleus is 100 fm (1 fm = 10^{-15} m) from a proton, which initially is at rest. When the proton is released, it speeds away because of the repulsion that it experiences due to the charge on the gold nucleus. What is the proton's speed a large distance (assume to be infinity) from the gold nucleus? (Assume the gold nucleus remains stationary.)

Picture the Problem The work done by the electric field of the gold nucleus changes the kinetic energy of the proton. We can apply the work-kinetic energy theorem to derive an expression for the speed of the proton as a function of its distance from the gold nucleus. Because the repulsive Coulomb force $\vec{F}_e$ varies with distance, we'll have to evaluate $\int \vec{F}_e \cdot d\vec{r}$ in order to find the work done on the proton by this force.

Apply the work-kinetic energy theorem to the proton to obtain:

$$W_{\text{net}} = \int_{r_0}^{\infty} \vec{\boldsymbol{F}}_{\text{e}} \cdot d\hat{\boldsymbol{r}} = \Delta K$$

or, because $\int_{r_0}^{\infty} \vec{\boldsymbol{F}}_{\text{e}} \cdot d\hat{\boldsymbol{r}} = \int_{r_0}^{\infty} \frac{ke(79e)}{r^2}dr$ and $K_{\text{i}} = 0$,

$$79ke^2 \int_{r_0}^{\infty} \frac{dr}{r^2} = \tfrac{1}{2} m_{\text{p}} v_{\text{f}}^2$$

Evaluating the integral yields:

$$-79ke^2\left[\frac{1}{r}\right]_{r_0}^{\infty} = \frac{79ke^2}{r_0} = \tfrac{1}{2} m_{\text{p}} v_{\text{f}}^2$$

Solve for v_{f} and simplify to obtain:

$$v_{\text{f}} = \sqrt{\frac{158ke^2}{m_{\text{p}} r_0}} = e\sqrt{\frac{158k}{m_{\text{p}} r_0}}$$

Substitute numerical values and evaluate v_{f}:

$$v_{\text{f}} = \left(1.602\times10^{-19}\,\text{C}\right)\sqrt{\frac{158\left(8.988\times10^{9}\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)}{\left(1.673\times10^{-27}\,\text{kg}\right)\left(1.00\times10^{-13}\,\text{m}\right)}} = \boxed{1.48\times10^{7}\,\text{m/s}}$$

85 ••• [SSM] During a famous experiment in 1919, Ernest Rutherford shot doubly ionized helium nuclei (also known as alpha particles) at a gold foil. He discovered that virtually all of the mass of an atom resides in an extremely compact nucleus. Suppose that during such an experiment, an alpha particle far from the foil has an initial kinetic energy of 5.0 MeV. If the alpha particle is aimed directly at the gold nucleus, and the only force acting on it is the electric force of repulsion exerted on it by the gold nucleus, how close will it approach the gold nucleus before turning back? That is, what is the minimum center-to-center separation of the alpha particle and the gold nucleus?

Comment: What????

Picture the Problem The work done by the electric field of the gold nucleus changes the kinetic energy of the alpha particle–eventually bringing it to rest. We can apply the work-kinetic energy theorem to derive an expression for the distance of closest approach. Because the repulsive Coulomb force $\vec{\boldsymbol{F}}_{\text{e}}$ varies with distance, we'll have to evaluate $\int \vec{\boldsymbol{F}}_{\text{e}} \cdot d\vec{\boldsymbol{r}}$ in order to find the work done on the alpha particles by this force.

Apply the work-kinetic energy theorem to the alpha particle to obtain:

$$W_{\text{net}} = \int_{\infty}^{r_{\min}} \vec{F}_{\text{e}} \cdot d\vec{r} = \Delta K$$

or, because

$$\int_{\infty}^{r_{\min}} \vec{F}_{\text{e}} \cdot d\vec{r} = -\int_{\infty}^{r_{\min}} \frac{k(2e)(79e)}{r^2}\,dr \text{ and}$$

$K_{\text{f}} = 0$,

$$-158ke^2 \int_{\infty}^{r_{\min}} \frac{dr}{r^2} = -K_{\text{i}}$$

Evaluating the integral yields:

$$-158ke^2\left[\frac{1}{r}\right]_{\infty}^{r_{\min}} = -\frac{158ke^2}{r_{\min}} = -K_{\text{i}}$$

Solve for $r_{\min}$ and simplify to obtain:

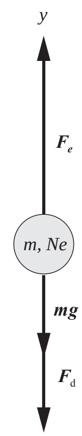
$$r_{\min} = \frac{158ke^2}{K_{\text{i}}}$$

Substitute numerical values and evaluate $r_{\min}$:

$$r_{\min} = \frac{158\left(8.988\times10^{9}\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.602\times10^{-19}\,\text{C}\right)^2}{5.0\,\text{Mev}\times\frac{1.602\times10^{-19}\,\text{J}}{\text{eV}}} = \boxed{4.6\times10^{-14}\ \text{m}}$$

86 ••• During the Millikan experiment used to determine the charge on the electron, a charged polystyrene microsphere is released in still air in a known vertical electric field. The charged microsphere will accelerate in the direction of the net force until it reaches terminal speed. The charge on the microsphere is determined by measuring the terminal speed. During one such experiment, the microsphere has radius of $r = 5.50 \times 10^{7}$ m, and the field has a magnitude $E = 6.00 \times 10^{4}$ N/C. The magnitude of the drag force on the sphere is given by $F_{\text{D}} = 6\pi\eta rv$, where v is the speed of the sphere and η is the viscosity of air ($\eta = 1.8 \times 10^{-5}$ N·s/m^2). Polystyrene has density 1.05×10^{3} kg/m^3. (*a*) If the electric field is pointing down and the polystyrene microsphere is rising with a terminal speed of 1.16×10^{-4} m/s, what is the charge on the sphere? (*b*) How many excess electrons are on the sphere? (*c*) If the direction of the electric field is reversed but its magnitude remains the same, what is the new terminal speed?

Picture the Problem The free body diagram shows the forces acting on the microsphere of mass m and having an excess charge of $q = Ne$ when the electric field is downward. Under terminal-speed conditions the sphere is in equilibrium under the influence of the electric force $\vec{F}_e$, its weight $m\vec{g}$, and the drag force $\vec{F}_d$. We can apply Newton's second law, under terminal-speed conditions, to relate the number of excess charges N on the sphere to its mass and, using Stokes' law, find its terminal speed.



(*a*) Apply Newton's second law to the microsphere to obtain:

$$F_e - mg - F_d = ma_y$$

or, because $a_y = 0$,

$$F_e - mg - F_{d,\text{terminal}} = 0$$

Substitute for F_e, m, and $F_{d,\text{terminal}}$ to obtain:

$$qE - \rho Vg - 6\pi\eta r v_t = 0$$

or, because $q = Ne$,

$$NeE - \tfrac{4}{3}\pi r^3\rho g - 6\pi\eta r v_t = 0$$

Solve for Ne to obtain:

$$Ne = \frac{\tfrac{4}{3}\pi r^3\rho g + 6\pi\eta r v_t}{E} \qquad (1)$$

Substitute numerical values and evaluate $\tfrac{4}{3}\pi r^3\rho g$:

$$\tfrac{4}{3}\pi r^3\rho g = \tfrac{4}{3}\pi\left(5.50\times10^{-7}\text{ m}\right)^3\left(1.05\times10^3\text{ kg/m}^3\right)\left(9.81\text{m/s}^2\right) = 7.18\times10^{-15}\text{ N}$$

Substitute numerical values and evaluate $6\pi\eta r v_t$:

$$6\pi\eta r v_t = 6\pi\left(1.8\times10^{-5}\text{ Pa}\cdot\text{s}\right)\left(5.50\times10^{-7}\text{ m}\right)\left(1.16\times10^{-4}\text{ m/s}\right) = 2.16\times10^{-14}\text{ N}$$

Substitute numerical values in equation (1) and evaluate Ne:

$$Ne = \frac{7.18\times10^{-15}\text{ N} + 2.16\times10^{-14}\text{ N}}{6.00\times10^4\text{ N/C}} = \boxed{4.8\times10^{-19}\text{ C}}$$

(*b*) Divide the result in (*a*) by e to obtain:

$$N = \frac{4.80\times10^{-19}\text{ C}}{1.602\times10^{-19}\text{ C}} = \boxed{3}$$

(*c*) With the field pointing upward, the electric force is downward and the application of $\sum F_y = ma_y$ to the bead yields:

$$F_{\text{d,terminal}} - F_{\text{e}} - mg = 0$$
or
$$6\pi\eta r v_{\text{t}} - NeE - \tfrac{4}{3}\pi r^3 \rho g = 0$$

Solve for v_{t} to obtain:

$$v_{\text{t}} = \frac{NeE + \tfrac{4}{3}\pi r^3 \rho g}{6\pi\eta r}$$

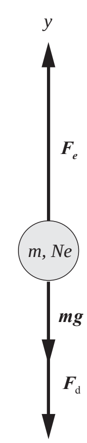
Substitute numerical values and evaluate v_{t}:

$$v_{\text{t}} = \frac{3\left(1.602\times10^{-19}\ \text{C}\right)\left(6.00\times10^{4}\ \dfrac{\text{N}}{\text{C}}\right) + \tfrac{4}{3}\pi\left(5.50\times10^{-7}\ \text{m}\right)^3\left(1.05\times10^{3}\ \dfrac{\text{kg}}{\text{m}^3}\right)\left(9.81\dfrac{\text{m}}{\text{s}^2}\right)}{6\pi\left(1.8\times10^{-5}\ \text{Pa}\cdot\text{s}\right)\left(5.50\times10^{-7}\ \text{m}\right)}$$

$$= \boxed{0.19\,\text{mm/s}}$$

87 ••• [SSM] In Problem 86, there is a description of the Millikan experiment used to determine the charge on the electron. During the experiment, a switch is used to reverse the direction of the electric field without changing its magnitude, so that one can measure the terminal speed of the microsphere both as it is moving upward and as it is moving downward. Let v_{u} represent the terminal speed when the particle is moving up, and v_{d} the terminal speed when moving down. (*a*) If we let $u = v_{\text{u}} + v_{\text{d}}$, show that $q = 3\pi\eta r u/E$, where q is the microsphere's net charge. For the purpose of determining q, what advantage does measuring both v_{u} and v_{d} have over measuring only one terminal speed?
(*b*) Because charge is quantized, u can only change by steps of magnitude N, where N is an integer. Using the data from Problem 86, calculate Δu.

Picture the Problem The free body diagram shows the forces acting on the microsphere of mass m and having an excess charge of $q = Ne$ when the electric field is downward. Under terminal-speed conditions the sphere is in equilibrium under the influence of the electric force $\vec{F}_{\text{e}}$, its weight $m\vec{g}$, and the drag force $\vec{F}_{\text{d}}$. We can apply Newton's second law, under terminal-speed conditions, to relate the number of excess charges N on the sphere to its mass and, using Stokes' law, to its terminal speed.



(*a*) Apply Newton's second law to the microsphere when the electric field is downward:

$$F_e - mg - F_d = ma_y$$

or, because $a_y = 0$,

$$F_e - mg - F_{d,\text{terminal}} = 0$$

Substitute for F_e and $F_{d,\text{terminal}}$ to obtain:

$$qE - mg - 6\pi\eta r v_u = 0$$

or, because $q = Ne$,

$$NeE - mg - 6\pi\eta r v_u = 0$$

Solve for v_u to obtain:

$$v_u = \frac{NeE - mg}{6\pi\eta r} \quad (1)$$

With the field pointing upward, the electric force is downward and the application of Newton's second law to the microsphere yields:

$$F_{d,\text{terminal}} - F_e - mg = 0$$

or

$$6\pi\eta r v_d - NeE - mg = 0$$

Solve for v_d to obtain:

$$v_d = \frac{NeE + mg}{6\pi\eta r} \quad (2)$$

Add equations (1) and (2) and simplify to obtain:

$$u = v_u + v_d = \frac{NeE - mg}{6\pi\eta r} + \frac{NeE + mg}{6\pi\eta r} = \frac{NeE}{3\pi\eta r} = \boxed{\frac{qE}{3\pi\eta r}}$$

Measuring both v_u and v_d has the advantage that you don't need to know the mass of the microsphere.

(*b*) Letting Δu represent the change in the terminal speed of the microsphere due to a gain (or loss) of one electron we have:

$$\Delta u = v_{N+1} - v_N$$

Noting that Δv will be the same whether the microsphere is moving upward or downward, express its terminal speed when it is moving upward with N electronic charges on it:

$$v_N = \frac{NeE - mg}{6\pi\eta r}$$

Express its terminal speed upward when it has $N + 1$ electronic charges:

$$v_{N+1} = \frac{(N+1)eE - mg}{6\pi\eta r}$$

Substitute and simplify to obtain:

$$\Delta u = \frac{(N+1)eE - mg}{6\pi\eta r} - \frac{NeE - mg}{6\pi\eta r} = \frac{eE}{6\pi\eta r}$$

Substitute numerical values and evaluate Δu:

$$\Delta u = \frac{(1.602\times10^{-19}\ \text{C})(6.00\times10^{4}\ \text{N/C})}{6\pi(1.8\times10^{-5}\ \text{Pa}\cdot\text{m})(5.50\times10^{-7}\ \text{m})} = \boxed{52\ \mu\text{m/s}}$$

Chapter 22
The Electric Field 2: Continuous Charge Distributions

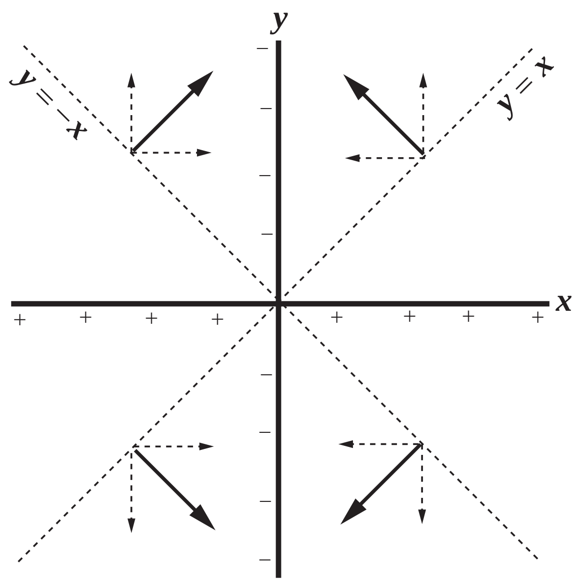
Conceptual Problems

1 • **[SSM]** Figure 22-37 shows an L-shaped object that has sides that are equal in length. Positive charge is distributed uniformly along the length of the object. What is the direction of the electric field along the dashed 45° line? Explain your answer.

Determine the Concept The resultant field is the superposition of the electric fields due to the charge distributions along the axes and is directed along the dashed line, pointing away from the intersection of the two sides of the L-shaped object. This can be seen by dividing each leg of the object into 10 (or more) equal segments and then drawing the electric field on the dashed line due to the charges on each pair of segments that are equidistant from the intersection of the legs.

2 • Positive charge is distributed uniformly along the entire length of the x axis, and negative charge is distributed uniformly along the entire length of the y axis. The charge per unit length on the two axes is identical, except for the sign. Determine the direction of the electric field at points on the lines defined by $y = x$ and $y = -x$. Explain your answer.

Determine the Concept The electric fields along the lines defined by $y = x$ and $y = -x$ are the superposition of the electric fields due to the charge distributions along the axes. The direction of the electric field is the direction of the force acting on a test charge at the point(s) of interest. Typical points are shown at two points on each of the two lines.



3 • True or false:

(*a*) The electric field due to a hollow uniformly charged thin spherical shell is zero at all points inside the shell.
(*b*) In electrostatic equilibrium, the electric field everywhere inside the material of a conductor must be zero.
(*c*) If the net charge on a conductor is zero, the charge density must be zero at every point on the surface of the conductor.

(*a*) True (assuming there are no charges inside the shell).

(*b*) True. The charges reside on the surface of conductor.

(*c*) False. Consider a spherical conducting shell. Such a surface will have equal charges on its inner and outer surfaces but, because their areas differ, so will their charge densities.

4 • If the electric flux through a closed surface is zero, must the electric field be zero everywhere on that surface? If not, give a specific example. From the given information can the net charge inside the surface be determined? If so, what is it?

Determine the Concept No, this is not necessarily true. The only conclusion that we can draw is that there is equal positive and negative flux. For example, the net flux through a Gaussian surface completely enclosing a dipole is zero. If the electric flux is zero through the closed surface, we can conclude that the net charge inside the surface is zero.

5 • True or false:

(*a*) Gauss's law holds only for symmetric charge distributions.
(*b*) The result that $E = 0$ everywhere inside the material of a conductor under electrostatic conditions can be derived from Gauss's law.

(*a*) False. Gauss's law states that the net flux through any surface is given by $\phi_{\text{net}} = \oint_S E_n\, dA = 4\pi k Q_{\text{inside}}$. While it is true that Gauss's law is easiest to apply to symmetric charge distributions, it holds for *any* surface.

(*b*) True. Because the charges on a conductor, under electrostatic conditions, reside on the surface of the conductor, the net flux inside the conductor is zero. Hence, by Gauss's law, the electric field inside the conductor must also be zero.

6 •• A single point charge q is located at the center of both an imaginary cube and an imaginary sphere. How does the electric flux through the surface of the cube compare to that through the surface of the sphere? Explain your answer.

Determine the Concept Because the net flux is proportional to the net charge enclosed, and this is the same for both surfaces, the electric flux through the surface of the cube is the same as the electric flux through the surface of the sphere.

7 •• **[SSM]** An electric dipole is completely inside a closed imaginary surface and there are no other charges. True or False:

(*a*) The electric field is zero everywhere on the surface.
(*b*) The electric field is normal to the surface everywhere on the surface.
(c) The electric flux through the surface is zero.
(*d*) The electric flux through the surface could be positive or negative.
(*e*) The electric flux through a portion of the surface might not be zero.

(*a*) False. Near the positive end of the dipole, the electric field, in accordance with Coulomb's law, will be directed outward and will be nonzero. Near the negative end of the dipole, the electric field, in accordance with Coulomb's law, will be directed inward and will be nonzero.

(*b*) False. The electric field is perpendicular to the Gaussian surface only at the intersections of the surface with a line defined by the axis of the dipole.

(*c*) True. Because the net charge enclosed by the Gaussian surface is zero, the net flux, given by $\phi_{\text{net}} = \oint_S E_n dA = 4\pi k Q_{\text{inside}}$, through this surface must be zero.

(*d*) False. The flux through the closed surface is zero.

(*e*) True. All Gauss's law tells us is that, because the net charge inside the surface is zero, the *net* flux through the surface must be zero.

8 •• Explain why the electric field strength increases linearly with r, rather than decreases inversely with r^2, between the center and the surface of a uniformly charged solid sphere.

Determine the Concept We can show that the charge inside a uniformly charged solid sphere of radius r is proportional to r^3 and that the area of a sphere is proportional to r^2. Using Gauss's law, it follows that the electric field must be proportional to $r^3/r^2 = r$.

Use Gauss's law to express the electric field inside a spherical charge distribution of constant volume charge density:

$$E = \frac{4\pi k Q_{\text{inside}}}{A}$$

where $A = 4\pi r^2$.

Express Q_{inside} as a function of ρ and r:

$$Q_{\text{inside}} = \rho V = \tfrac{4}{3}\pi\rho r^3$$

Substitute for Q_{inside} to obtain:

$$E = \frac{4\pi k \tfrac{4}{3}\pi\rho r^3}{4\pi r^2} = \frac{4k\pi\rho}{3}r$$

This result shows that the electric field *increases* linearly as you move out from the center of a spherical charge distribution.

9 •• **[SSM]** Suppose that the total charge on the conducting spherical shell in Figure 22-38 is zero. The negative point charge at the center has a magnitude given by Q. What is the direction of the electric field in the following regions? (*a*) $r < R_1$, (*b*) $R_2 > r > R_1$, (*c*) and $r > R_2$. Explain your answer.

Determine the Concept We can apply Gauss's law to determine the electric field for $r < R_1$, $R_2 > r > R_1$, and $r > R_2$. We also know that the direction of an electric field at any point is determined by the direction of the electric force acting on a positively charged object located at that point.

(*a*) From the application of Gauss's law we know that the electric field in this region is not zero. A positively charged object placed in the region for which $r < R_1$ will experience an attractive force from the charge $-Q$ located at the center of the shell. Hence the direction of the electric field is radially inward.

(*b*) Because the total charge on the conducting sphere is zero, the charge on its inner surface must be positive (the positive charges in the conducting sphere are drawn there by the negative charge at the center of the shell) and the charge on its outer surface must be negative. Hence the electric field in the region $R_2 > r > R_1$ is radially outward.

(*c*) Because the charge on the outer surface of the conducting shell is negative, the electric field in the region $r > R_2$ is radially inward.

10 •• The conducting shell in Figure 22-38 is grounded, and the negative point charge at the center has a magnitude given by Q. Which of the following statements is correct?

(*a*) The charge on the inner surface of the shell is $+Q$ and the charge on the outer surface is $-Q$.
(*b*) The charge on the inner surface of the shell is $+Q$ and the charge on the outer surface is zero.
(*c*) The charge on both surfaces of the shell is $+Q$.
(*d*) The charge on both surfaces of the shell is zero.

Determine the Concept We can decide what will happen when the conducting shell is grounded by thinking about the distribution of charge on the shell before it is grounded and the effect on this distribution of grounding the shell.

The negative point charge at the center of the conducting shell induces a positive charge on the inner surface of the shell and a negative charge on the outer surface. Grounding the shell attracts positive charge from ground; resulting in the outer surface becoming electrically neutral. $\boxed{(b)}$ is correct.

11 •• **T**he conducting shell in Figure 22-38 is grounded, and the negative point charge at the center has a magnitude given by Q. What is the direction of the electric field in the following regions? (*a*) $r < R_1$, (*b*) $R_2 > r > R_1$, (*c*) and $r > R_2$. Explain your answers.

Determine the Concept We can apply Gauss's law to determine the electric field for $r < R_1$, $R_2 > r > R_1$, and $r > R_2$. We also know that the direction of an electric field at any point is determined by the direction of the electric force acting on a positively charged object located at that point.

(*a*) From the application of Gauss's law we know that the electric field in this region is not zero. A positively charged object placed in the region for which $r < R_1$ will experience an attractive force from the charge $-Q$ located at the center of the shell. Hence the direction of the electric field is radially inward.

(*b*) Because the conducting shell is grounded, its inner surface is positively charged and its outer surface will have zero net charge. Hence the electric field in the region $R_2 > r > R_1$ is radially outward.

(*c*) Because the conducting shell is grounded, the net charge on the outer surface of the conducting shell is zero, and the electric field in the region $r > R_2$ is zero.

Estimation and Approximation

12 •• In the chapter, the expression for the electric field due to a uniformly charged disk (on its axis), was derived. At any location on the axis, the field

magnitude is $|E| = 2\pi k\sigma\left[1-\left(1+\frac{R^2}{z^2}\right)^{-1/2}\right]$. At large distances ($|z| >> R$), it was shown that this equation approaches $E \approx kQ/z^2$. Very near the disk ($|z| << R$), the field strength is approximately that of an infinite plane of charge or $|E| \approx 2\pi k\sigma$. Suppose you have a disk of radius 2.5 cm that has a uniform surface charge density of 3.6 μC/m^2. Use both the exact and appropriate expression from those given above to find the electric-field strength on the axis at distances of (*a*) 0.010 cm, (*b*) 0.040 cm, and (*c*) 5.0 m. Compare the two values in each case and comment on the how well the approximations work in their region of validity.

Picture the Problem For $z << R$, we can model the disk as an infinite plane. For $z >> R$, we can approximate the ring charge by a point charge.

(*a*) Evaluate the exact expression for z = 0.010 cm:

$$|E|_{z=0.010\,\text{cm}} = 2\pi\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.6\,\mu\text{C/m}^2\right)\left(1-\left(1+\frac{(2.5\ \text{cm})^2}{(0.010\ \text{cm})^2}\right)^{-1/2}\right)$$
$$= 2.025\times10^{5}\ \text{N/C} = \boxed{2.0\times10^{5}\ \text{N/C}}$$

For $z << R$, the electric field strength near an infinite plane of charge is given by:

$$|E| \approx 2\pi k\sigma$$

Evaluate the approximate expression for z = 0.010 cm:

$$|E|_{\text{approx}} = 2\pi\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.6\,\mu\text{C/m}^2\right) = 2.033\times10^{5}\ \text{N/C}$$
$$= \boxed{2.0\times10^{5}\ \text{N/C}}$$

The approximate value agrees to within 0.40% with the exact value and is larger than the exact value.

(*b*) Evaluate the exact expression for $z = 0.040$ cm:

$$\left|E\right|_{z=0.040\,\text{cm}} = 2\pi\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.6\,\mu\text{C/m}^2\right)\left(1-\left(1+\frac{(2.5\ \text{cm})^2}{(0.040\ \text{cm})^2}\right)^{-1/2}\right)$$

$$= 2.001\times10^{5}\ \text{N/C} = \boxed{2.0\times10^{5}\ \text{N/C}}$$

The approximate value agrees to within 1.2% with the exact value and is smaller than the exact value.

(*c*) Evaluate the exact expression for $z = 5.0$ m:

$$\left|E\right|_{z=5.0\,\text{m}} = 2\pi\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.6\,\mu\text{C/m}^2\right)\left(1-\left(1+\frac{(2.5\ \text{cm})^2}{(5.0\ \text{m})^2}\right)^{-1/2}\right)$$

$$= 2.541\ \text{N/C} = \boxed{2.5\ \text{N/C}}$$

Because $z >> R$, we can use Coulomb's law for the electric field due to a point charge to obtain:

$$\left|E(z)\right| = \frac{kQ}{z^2} = \frac{k\pi r^2\sigma}{z^2}$$

Evaluate $\left|E(5.0\ \text{m})\right|$:

$$\left|E(5.0\,\text{m})\right|_{\text{approx}} = \frac{\pi\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(2.5\,\text{cm})^2\left(3.6\,\mu\text{C/m}^2\right)}{(5.0\,\text{m})^2} = 2.541\,\text{N/C}$$

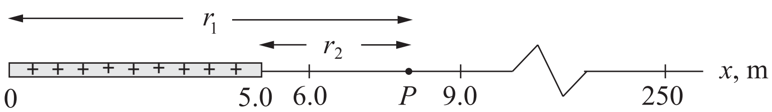
$$= \boxed{2.5\,\text{N/C}}$$

The approximate value agrees, to four significant figures, with the exact value.

Calculating $\vec{E}$ From Coulomb's Law

13 •• [SSM] A uniform line charge that has a linear charge density λ equal to 3.5 nC/m is on the x axis between $x = 0$ and $x = 5.0$ m. (*a*) What is its total charge? Find the electric field on the x axis at (*b*) $x = 6.0$ m, (*c*) $x = 9.0$ m, and (*d*) $x = 250$ m. (*e*) Estimate the electric field at $x = 250$ m, using the approximation that the charge is a point charge on the x axis at $x = 2.5$ m, and compare your result with the result calculated in Part (*d*). (To do this you will need to assume that the values given in this problem statement are valid to more than two significant figures.) Is your approximate result greater or smaller than the exact result? Explain your answer.

Picture the Problem (*a*) We can use the definition of λ to find the total charge of the line of charge. (*b*), (*c*) and (*d*) Equation 22-2*b* gives the electric field on the axis of a finite line of charge. In Part (*e*) we can apply Coulomb's law for the electric field due to a point charge to approximate the electric field at x = 250 m. In the following diagram, L = 5.0 m and P is a generic point on the x axis.



(*a*) Use the definition of linear charge density to express Q in terms of λ:

$$Q = \lambda L = (3.5\,\text{nC/m})(5.0\,\text{m}) = 17.5\,\text{nC} = \boxed{18\,\text{nC}}$$

The electric field on the axis of a finite line charge is given by Equation 22-2*b*:

$$E_x = k\lambda\left(\frac{1}{r_2} - \frac{1}{r_1}\right)$$

(*b*) Substitute numerical values and evaluate $E_{x=6.0\,\text{m}}$:

$$E_{x=6.0\,\text{m}} = \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(3.5\times10^{-9}\,\frac{\text{C}}{\text{m}}\right)\left(\frac{1}{6.0\,\text{m}-5.0\,\text{m}} - \frac{1}{6.0\,\text{m}}\right) = \boxed{26\,\text{N/C}}$$

(*c*) Substitute numerical values and evaluate $E_{x=9.0\,\text{m}}$:

$$E_{x=9.0\,\text{m}} = \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(3.5\times10^{-9}\,\frac{\text{C}}{\text{m}}\right)\left(\frac{1}{9.0\,\text{m}-5.0\,\text{m}} - \frac{1}{9.0\,\text{m}}\right) = \boxed{4.4\,\text{N/C}}$$

(*d*) Substitute numerical values and evaluate E_x at x = 250 m:

$$E_{x=250\,\text{m}} = \left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(3.5\times10^{-9}\,\frac{\text{C}}{\text{m}}\right)\left(\frac{1}{250\,\text{m}-5.0\,\text{m}} - \frac{1}{250\,\text{m}}\right)$$
$$= 2.56800\,\text{mN/C} = \boxed{2.6\,\text{mN/C}}$$

(*e*) Using the approximation that the charge is a point charge on the x axis at x = 2.5 m, Coulomb's law gives:

$$E_x = \frac{kQ}{\left(r_1 - \frac{1}{2}L\right)^2}$$

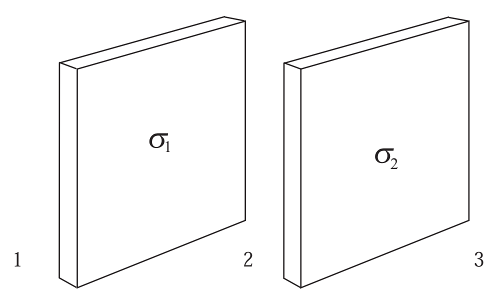
Substitute numerical values and evaluate $E_{x=250\text{ m}}$:

$$E_{x=250\text{ m}} = \frac{\left(8.988\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2\right)\left(17.5\text{ nC}\right)}{\left(250\text{ m}-\frac{1}{2}\left(5.0\text{ m}\right)\right)^2} = 2.56774\text{ mN/C} = \boxed{2.6\text{ mN/C}}$$

This result is about 0.01% less than the exact value obtained in (*d*). This suggests that the line of charge is too long for its field at a distance of 250 m to be modeled exactly as that due to a point charge.

14 • Two infinite nonconducting sheets of charge are parallel to each other, with sheet A in the $x = -2.0$ m plane and sheet B in the $x = +2.0$ m plane. Find the electric field in the region $x < -2.0$ m, in the region $x > +2.0$ m, and between the sheets for the following situations. (*a*) When each sheet has a uniform surface charge density equal to $+3.0\ \mu\text{C/m}^2$ and (*b*) when sheet A has a uniform surface charge density equal to $+3.0\ \mu\text{C/m}^2$ and sheet B has a uniform surface charge density equal to $-3.0\ \mu\text{C/m}^2$. (*c*) Sketch the electric field-line pattern for each case.

Picture the Problem Choose a coordinate system in which the $+x$ direction is perpendicular to the surfaces and points to the right. Let the charge densities on the two plates be σ_1 and σ_2 and denote the three regions of interest as 1, 2, and 3. Choose a coordinate system in which the positive x direction is to the right. We can apply the equation for $\vec{E}$ near an infinite plane of charge and the superposition of fields to find the field in each of the three regions.



(*a*) Use the equation for $\vec{E}$ near an infinite plane of charge to express the field in region 1 when $\sigma_1 = \sigma_2 = +3.0\ \mu\text{C/m}^2$:

$$\begin{aligned}\vec{E}_1 &= \vec{E}_{\sigma_1} + \vec{E}_{\sigma_2} \\ &= -2\pi k\sigma_1\hat{i} - 2\pi k\sigma_2\hat{i} \\ &= -4\pi k\sigma\,\hat{i}\end{aligned}$$

Substitute numerical values and evaluate $\vec{E}_1$:

$$\vec{E}_1 = -4\pi\left(8.988\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2\right)\left(3.0\ \mu\text{C/m}^2\right)\hat{i} = \boxed{-\left(3.4\times10^{5}\text{ N/C}\right)\hat{i}}$$

Proceed as above for region 2:

$$\vec{E}_2 = \vec{E}_{\sigma_1} + \vec{E}_{\sigma_2} = 2\pi k\sigma_1\hat{i} - 2\pi k\sigma_2\hat{i}$$
$$= 2\pi k\sigma\,\hat{i} - 2\pi k\sigma\,\hat{i}$$
$$= \boxed{0}$$

Proceed as above for region 3:

$$\vec{E}_3 = \vec{E}_{\sigma_1} + \vec{E}_{\sigma_2} = 2\pi k\sigma_1\hat{i} + 2\pi k\sigma_2\hat{i} = 4\pi k\sigma\,\hat{i}$$
$$= 4\pi\left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(3.0\ \mu\text{C/m}^2\right)\hat{i}$$
$$= \boxed{\left(3.4\times10^5\ \text{N/C}\right)\hat{i}}$$

(*b*) Use the equation for $\vec{E}$ near an infinite plane of charge to express and evaluate the field in region 1 when $\sigma_1 = +3.0\ \mu\text{C/m}^2$ and $\sigma_2 = -3.0\ \mu\text{C/m}^2$:

$$\vec{E}_1 = \vec{E}_{\sigma_1} + \vec{E}_{\sigma_2} = 2\pi k\sigma_1\hat{i} - 2\pi k\sigma_2\hat{i}$$
$$= 2\pi k\sigma\,\hat{i} - 2\pi k\sigma\,\hat{i}$$
$$= \boxed{0}$$

Proceed as above for region 2:

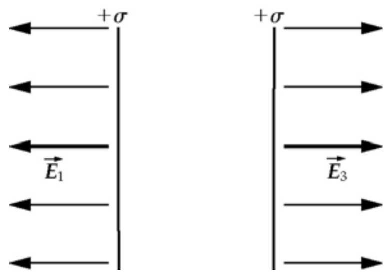
$$\vec{E}_2 = \vec{E}_{\sigma_1} + \vec{E}_{\sigma_2} = 2\pi k\sigma_1\hat{i} + 2\pi k\sigma_2\hat{i} = 4\pi k\sigma\,\hat{i}$$
$$= 4\pi\left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(3.0\ \mu\text{C/m}^2\right)\hat{i}$$
$$= \boxed{\left(3.4\times10^5\ \text{N/C}\right)\hat{i}}$$

Proceed as above for region 3:

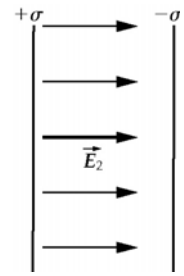
$$\vec{E}_3 = \vec{E}_{\sigma_1} + \vec{E}_{\sigma_2} = 2\pi k\sigma_1\hat{i} - 2\pi k\sigma_2\hat{i}$$
$$= 2\pi k\sigma\,\hat{i} - 2\pi k\sigma\,\hat{i}$$
$$= \boxed{0}$$

(c) The electric field lines for (a) and (b) are shown below:

(a)



(b)



15 • A charge of 2.75 μC is uniformly distributed on a ring of radius 8.5 cm. Find the electric field strength on the axis at distances of (a) 1.2 cm, (b) 3.6 cm, and (c) 4.0 m from the center of the ring. (d) Find the field strength at 4.0 m using the approximation that the ring is a point charge at the origin, and compare your results for Parts (c) and (d). Is your approximate result a good one? Explain your answer.

Picture the Problem The magnitude of the electric field at a distance z on the axis of a ring of charge Q and radius a is given by $E_z = \dfrac{kQz}{\left(z^2+a^2\right)^{3/2}}$.

Express $\vec{\boldsymbol{E}}$ on the axis of a ring charge:

$$E_z = \frac{kQz}{\left(z^2+a^2\right)^{3/2}}$$

(a) Substitute numerical values and evaluate E_z for z = 1.2 cm:

$$E_{z=1.2\,\text{cm}} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(2.75\,\mu\text{C})(1.2\,\text{cm})}{\left[(1.2\,\text{cm})^2+(8.5\,\text{cm})^2\right]^{3/2}} = \boxed{4.7\times10^5\ \text{N/C}}$$

(b) Proceed as in (a) with z = 3.6 cm:

$$E_{z=3.6\,\text{cm}} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(2.75\,\mu\text{C})(3.6\,\text{cm})}{\left[(3.6\,\text{cm})^2+(8.5\,\text{cm})^2\right]^{3/2}} = \boxed{1.1\times10^6\ \text{N/C}}$$

(c) Proceed as in (a) with z = 4.0 m:

$$E_{z=4.0\,\text{m}} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(2.75\,\mu\text{C})(4.0\,\text{m})}{\left[(4.0\,\text{m})^2+(8.5\,\text{cm})^2\right]^{3/2}} = \boxed{1.5\times10^3\ \text{N/C}}$$

(*d*) Using Coulomb's law for the electric field due to a point charge, express E_z:

$$E_z = \frac{kQ}{z^2}$$

Substitute numerical values and evaluate $E_{z=4.0\,\text{m}}$:

$$E_{z=4.0\,\text{m}} = \frac{(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2.75\,\mu\text{C})}{(4.0\,\text{m})^2} = \boxed{1.5\times10^3\ \text{N/C}}$$

While this result agrees exactly, to two significant figures, with the result obtained in Part (*c*), it should be slightly larger because the point charge is nearer $z = 4.0$ m than is the ring of charge.

16 • A non-conducting disk of radius R lies in the $z = 0$ plane with its center at the origin. The disk has a uniform surface charge density σ. Find the value of z for which $E_z = \sigma/\left(4\in_0\right)$. Note that at this distance, the magnitude of the electric-field strength is half the electric-field strength at points on the x axis that are very close to the disk.

Picture the Problem The magnitude of the electric field at an axial distance z from a disk that has a uniform charge density σ and whose radius is R is given by

$$E_z = 2\pi k\sigma\left(1-\frac{1}{\sqrt{1+\frac{R^2}{z^2}}}\right).$$

We can equate this expression and $E_z = \frac{1}{2}\sigma/\left(2\in_0\right)$ and solve for z.

Express the electric field on the axis of a disk charge:

$$E_z = 2\pi k\sigma\left(1-\frac{1}{\sqrt{1+\frac{R^2}{z^2}}}\right)$$

We're given that:

$$E_z = \tfrac{1}{2}\sigma/\left(2\in_0\right) = \frac{\sigma}{4\in_0}$$

Equating these expressions gives:

$$\frac{\sigma}{4\in_0} = 2\pi k\sigma\left(1-\frac{1}{\sqrt{1+\frac{R^2}{z^2}}}\right)$$

Substituting for k yields:

$$\frac{\sigma}{4\in_0}=2\pi\left(\frac{1}{4\pi\in_0}\right)\sigma\left(1-\frac{1}{\sqrt{1+\frac{R^2}{z^2}}}\right)$$

Solve for z to obtain:

$$z=\boxed{\frac{R}{\sqrt{3}}}$$

17 • [SSM] A ring that has radius a lies in the $z = 0$ plane with its center at the origin. The ring is uniformly charged and has a total charge Q. Find E_z on the z axis at (a) $z = 0.2a$, (b) $z = 0.5a$, (c) $z = 0.7a$, (d) $z = a$, and (e) $z = 2a$. (f) Use your results to plot E_z versus z for both positive and negative values of z. (Assume that these distances are exact.)

Picture the Problem The electric field at a distance z from the center of a ring whose charge is Q and whose radius is a is given by $E_z=\frac{kQz}{\left(z^2+a^2\right)^{3/2}}$.

(a) Evaluating $E_{z=0.2a}$ gives:

$$E_{z=0.2a}=\frac{kQ(0.2a)}{\left[(0.2a)^2+a^2\right]^{3/2}}=\boxed{0.189\frac{kQ}{a^2}}$$

(b) Evaluating $E_{z=0.5a}$ gives:

$$E_{z=0.5a}=\frac{kQ(0.5a)}{\left[(0.5a)^2+a^2\right]^{3/2}}=\boxed{0.358\frac{kQ}{a^2}}$$

(c) Evaluating $E_{z=0.7a}$ gives:

$$E_{z=0.7a}=\frac{kQ(0.7a)}{\left[(0.7a)^2+a^2\right]^{3/2}}=\boxed{0.385\frac{kQ}{a^2}}$$

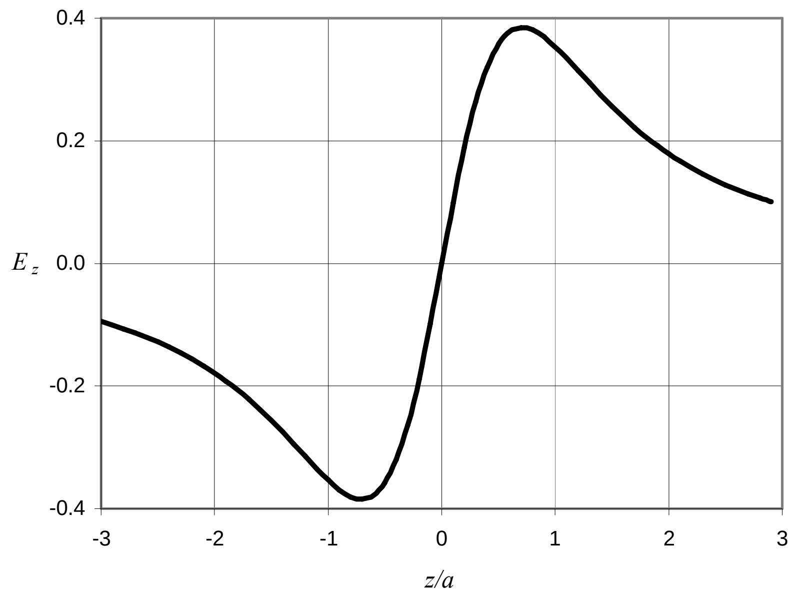
(d) Evaluating $E_{z=a}$ gives:

$$E_{z=a}=\frac{kQa}{\left[a^2+a^2\right]^{3/2}}=\boxed{0.354\frac{kQ}{a^2}}$$

(e) Evaluating $E_{z=2a}$ gives:

$$E_{z=2a}=\frac{2kQa}{\left[(2a)^2+a^2\right]^{3/2}}=\boxed{0.179\frac{kQ}{a^2}}$$

(f) The field along the z axis is plotted below. The z coordinates are in units of z/a and E is in units of kQ/a^2.



18 • A non-conducting disk of radius a lies in the $z = 0$ plane with its center at the origin. The disk is uniformly charged and has a total charge Q. Find E_z on the z axis at (a) $z = 0.2a$, (b) $z = 0.5a$, (c) $z = 0.7a$, (d) $z = a$, and (e) $z = 2a$. (f) Use your results to plot E_z versus z for both positive and negative values of z. (Assume that these distances are exact.)

Picture the Problem The magnitude of the electric field at a distance z from the center of a ring whose charge density is σ and whose radius is a is given by

$$E_z = 2\pi k\sigma\left(1-\frac{1}{\sqrt{1+\frac{a^2}{z^2}}}\right).$$

The magnitude of the electric field on the axis of a charged disk of radius a is given by:

$$E_z = 2\pi k\sigma\left(1-\frac{1}{\sqrt{1+\frac{a^2}{z^2}}}\right)$$

$$= \frac{Q}{2\pi \in_0 a^2}\left(1-\frac{1}{\sqrt{1+\frac{a^2}{z^2}}}\right)$$

(*a*) Evaluating $E_{z=0.2a}$ gives:

$$E_{z=0.2a} = \frac{Q}{2\pi \in_0 a^2}\left(1 - \frac{1}{\sqrt{1 + \frac{a^2}{(0.2a)^2}}}\right)$$

$$= \boxed{0.128\frac{Q}{\in_0 a^2}}$$

(*b*) Evaluating $E_{z=0.5a}$ gives:

$$E_{z=0.5a} = \frac{Q}{2\pi \in_0 a^2}\left(1 - \frac{1}{\sqrt{1 + \frac{a^2}{(0.5a)^2}}}\right)$$

$$= \boxed{0.088\frac{Q}{\in_0 a^2}}$$

(*c*) Evaluating $E_{z=0.7a}$ gives:

$$E_{z=0.7a} = \frac{Q}{2\pi \in_0 a^2}\left(1 - \frac{1}{\sqrt{1 + \frac{a^2}{(0.7a)^2}}}\right)$$

$$= \boxed{0.068\frac{Q}{\in_0 a^2}}$$

(*d*) Evaluating $E_{z=a}$ gives:

$$E_{z=a} = \frac{Q}{2\pi \in_0 a^2}\left(1 - \frac{1}{\sqrt{1 + \frac{a^2}{a^2}}}\right)$$

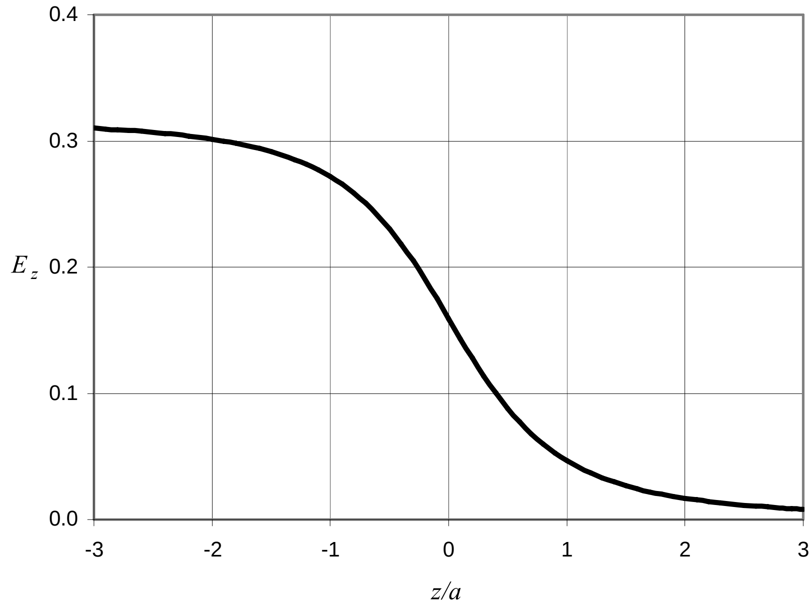
$$= \boxed{0.047\frac{Q}{\in_0 a^2}}$$

(*e*) Evaluating $E_{z=2a}$ gives:

$$E_{z=2a} = \frac{Q}{2\pi \in_0 a^2}\left(1 - \frac{1}{\sqrt{1 + \frac{a^2}{(2a)^2}}}\right)$$

$$= \boxed{0.017\frac{Q}{\in_0 a^2}}$$

The field along the z axis is plotted below. The z coordinates are in units of z/a and E_z is in units of $\dfrac{Q}{\epsilon_0\, a^2}$.



19 •• (a) Using a **spreadsheet** program or graphing calculator, make a graph of the electric field strength on the axis of a disk that has a radius a = 30.0 cm and a surface charge density σ = 0.500 nC/m^2. (b) Compare your results to the results based on the approximation $E = 2\pi k\sigma$ (the formula for the electric-field strength of a uniformly charged infinite sheet). At what distance does the solution based on approximation differ from the exact solution by 10.0 percent?

Picture the Problem The magnitude of the electric field on the z axis of a disk of radius a carrying a surface charge density σ is given by

$$E_z = 2\pi k\sigma\left(1-\frac{1}{\sqrt{1+\dfrac{a^2}{z^2}}}\right) = 2\pi k\sigma\left(1-\frac{z}{\sqrt{z^2+a^2}}\right).$$

The electric field due to an infinite sheet of charge density σ is independent of the distance from the plane and is given by $E_{\text{sheet}} = 2\pi k\sigma$.

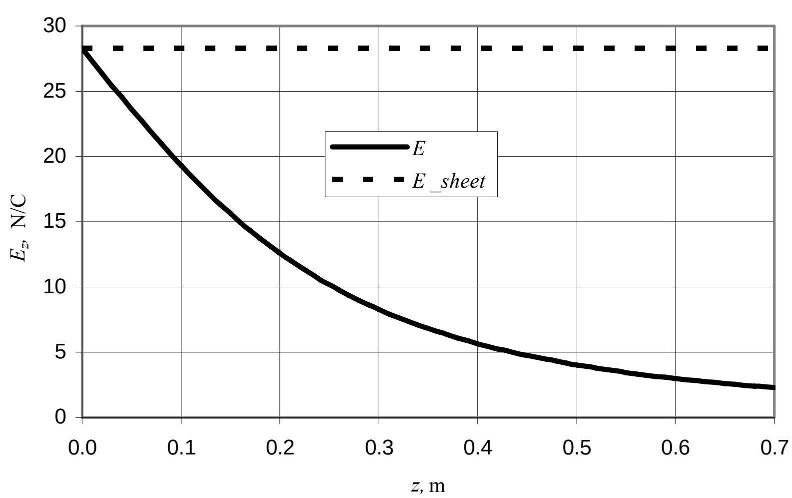
(a) A spreadsheet program to graph E_z is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
B3	9.00E+09	k
B4	5.00E−10	σ
B5	0.3	a

A8	0	z_0
A9	0.01	$x_0 + 0.01$
B8	2*PI()*$B$3*$B$4*(1−A8/(A8^2+$B$5^2)^2)^0.5)	$2\pi k\sigma\left(1-\dfrac{z}{\sqrt{z^2+a^2}}\right)$
C8	2*PI()*$B$3*$B$4	$2\pi k\sigma$

	A	B	C
1			
2			
3	k=	9.00E+09	N·m²/C²
4	σ=	5.00E-10	C/m²
5	a=	0.300	m
6			
7	z	E_z	E_{sheet}
8	0.00	28.27	28.3
9	0.01	27.33	28.3
77	0.69	2.34	28.3
78	0.70	2.29	28.3

(*b*) A graph of E_z follows. The electric field from an infinite sheet with the same charge density is shown for comparison. The magnitudes differ by more than 10.0 percent for $x \geq 0.0300$ m.



20 •• (*a*) Show that the electric-field strength E on the axis of a ring charge of radius a has maximum values at $z = \pm a/\sqrt{2}$. (*b*) Sketch the field strength E versus z for both positive and negative values of z. (*c*) Determine the maximum value of E.

Picture the Problem The electric field on the axis of a ring charge as a function of distance z along the axis from the center of the ring is given by $E_z = \frac{kQz}{\left(z^2+a^2\right)^{3/2}}$. We can show that it has its maximum and minimum values at $z = +a/\sqrt{2}$ and $z = -a/\sqrt{2}$ by setting its first derivative equal to zero and solving the resulting equation for z. The graph of E_z will confirm that the maximum and minimum occur at these coordinates.

(*a*) The variation of E_z with z on the axis of a ring charge is given by:

$$E_z = \frac{kQz}{\left(z^2+a^2\right)^{3/2}}$$

Differentiate this expression with respect to z to obtain:

$$\frac{dE_x}{dz} = kQ\frac{d}{dz}\left[\frac{x}{\left(z^2+a^2\right)^{3/2}}\right] = kQ\frac{\left(z^2+a^2\right)^{3/2} - z\frac{d}{dz}\left(z^2+a^2\right)^{3/2}}{\left(z^2+a^2\right)^{3}}$$

$$= kQ\frac{\left(z^2+a^2\right)^{3/2} - z\left(\tfrac{3}{2}\right)\left(z^2+a^2\right)^{1/2}(2z)}{\left(z^2+a^2\right)^{3}} = kQ\frac{\left(z^2+a^2\right)^{3/2} - 3z^2\left(z^2+a^2\right)^{1/2}}{\left(z^2+a^2\right)^{3}}$$

Set this expression equal to zero for extrema and simplify:

$$\frac{\left(z^2+a^2\right)^{3/2} - 3z^2\left(z^2+a^2\right)^{1/2}}{\left(z^2+a^2\right)^{3}} = 0,$$

$$\left(z^2+a^2\right)^{3/2} - 3z^2\left(z^2+a^2\right)^{1/2} = 0,$$

and

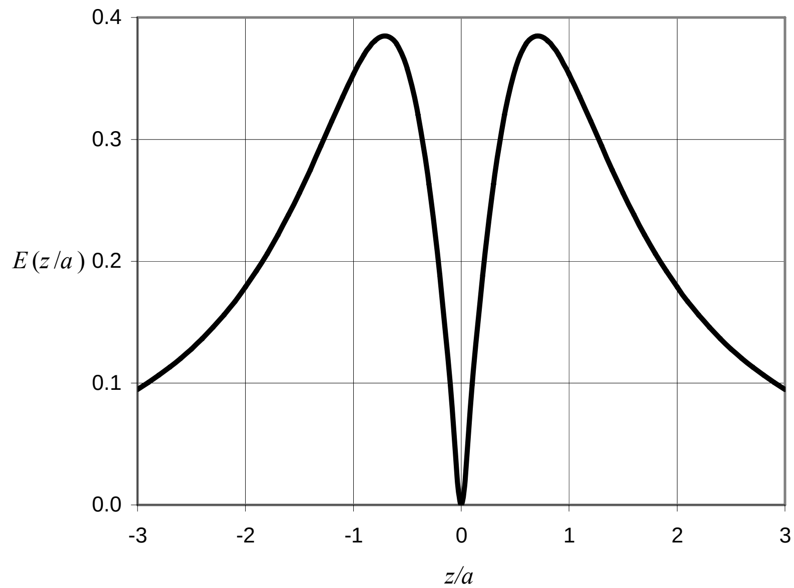
$$z^2 + a^2 - 3z^2 = 0$$

Solving for z yields:

$$z = \boxed{\pm\frac{a}{\sqrt{2}}}$$

as our candidates for maxima or minima.

(*b*) A graph of the magnitude of E_z, in units of kQ/a^2, versus z/a follows. This graph shows that the extrema at $z = \pm a/\sqrt{2}$ are, in fact, maxima.



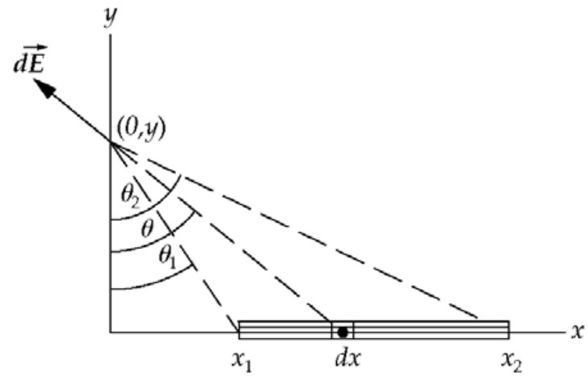
(*c*) Evaluate $E_z\left(\pm\frac{a}{\sqrt{2}}\right)$ and simplify to obtain the maximum value of the magnitude of E_z:

$$E_{z,\max} = E_{z=\pm\frac{a}{\sqrt{2}}} = \left|\frac{kQ\left(\pm\frac{a}{\sqrt{2}}\right)}{\left(\left(\pm\frac{a}{\sqrt{2}}\right)^2 + a^2\right)^{3/2}}\right| = \frac{kQ\frac{a}{\sqrt{2}}}{\left(\frac{1}{2}a^2 + a^2\right)^{3/2}} = \boxed{\frac{2\sqrt{3}}{9}\frac{kQ}{a^2}}$$

Remarks: Note that our result in Part (*c*) confirms the maxima obtained graphically in Part (*b*).

21 •• A line charge that has a uniform linear charge density λ lies along the x axis from $x = x_1$ to $x = x_2$ where $x_1 < x_2$. Show that the x component of the electric field at a point on the y-axis is given by $E_x = \frac{k\lambda}{y}\left(\cos\theta_2 - \cos\theta_1\right)$ where $\theta_1 = \tan^{-1}(x_1/y)$, $\theta_2 = \tan^{-1}(x_2/y)$ and $y \neq 0$.

Picture the Problem The line charge and point (0, y) are shown in the diagram. Also shown is a line element of length dx and the field $d\vec{E}$ its charge produces at (0, y). We can find dE_x from $d\vec{E}$ and then integrate from $x = x_1$ to $x = x_2$.



Express the x component of $d\vec{\mathbf{E}}$:

$$dE_x = -\frac{k\lambda}{x^2 + y^2}\sin\theta dx$$
$$= -\frac{k\lambda}{x^2 + y^2}\frac{x}{\sqrt{x^2 + y^2}}dx$$
$$= -\frac{k\lambda x}{\left(x^2 + y^2\right)^{3/2}}dx$$

Integrate from $x = x_1$ to x_2 and simplify to obtain:

$$E_x = -k\lambda\int_{x_1}^{x_2}\frac{x}{\left(x^2 + y^2\right)^{3/2}}dx$$
$$= -k\lambda\left[-\frac{1}{\sqrt{x^2 + y^2}}\right]_{x_1}^{x_2}$$
$$= -k\lambda\left[-\frac{1}{\sqrt{x_2^2 + y^2}} + \frac{1}{\sqrt{x_1^2 + y^2}}\right]$$
$$= -\frac{k\lambda}{y}\left[-\frac{y}{\sqrt{x_2^2 + y^2}} + \frac{y}{\sqrt{x_1^2 + y^2}}\right]$$

From the diagram we see that:

$$\cos\theta_2 = \frac{y}{\sqrt{x_2^2 + y^2}} \text{ or } \theta_2 = \tan^{-1}\left(\frac{x_2}{y}\right)$$

and

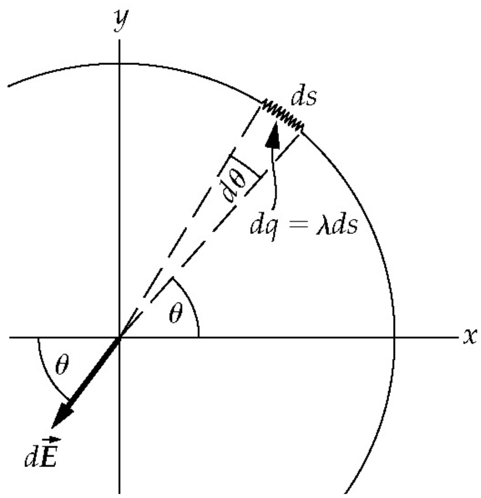
$$\cos\theta_1 = \frac{y}{\sqrt{x_1^2 + y^2}} \text{ or } \theta_1 = \tan^{-1}\left(\frac{x_1}{y}\right)$$

Substitute for $\frac{y}{\sqrt{x_2^2+y^2}}$ and $\frac{y}{\sqrt{x_1^2+y^2}}$ to obtain:

$$E_x = -\frac{k\lambda}{y}\left[-\cos\theta_2 + \cos\theta_1\right]$$
$$= \boxed{\frac{k\lambda}{y}\left[\cos\theta_2 - \cos\theta_1\right]}$$

22 •• A ring of radius a has a charge distribution on it that varies as $\lambda(\theta) = \lambda_0 \sin\theta$, as shown in Figure 22-39. (*a*) What is the direction of the electric field at the center of the ring? (*b*) What is the magnitude of the field at the center of the ring?

Picture the Problem The following diagram shows a segment of the ring of length ds that has a charge $dq = \lambda ds$. We can express the electric field $d\vec{E}$ at the center of the ring due to the charge dq and then integrate this expression from $\theta = 0$ to 2π to find the magnitude of the field in the center of the ring.



(*a*) and (*b*) The field $d\vec{E}$ at the center of the ring due to the charge dq is:

$$d\vec{E} = d\vec{E}_x + d\vec{E}_y = -dE\cos\theta\,\hat{\boldsymbol{i}} - dE\sin\theta\,\hat{\boldsymbol{j}} \quad (1)$$

The magnitude dE of the field at the center of the ring is:

$$dE = \frac{kdq}{r^2}$$

Because $dq = \lambda ds$:

$$dE = \frac{k\lambda ds}{r^2}$$

The linear charge density varies with θ according to $\lambda(\theta) = \lambda_0 \sin\theta$:

$$dE = \frac{k\lambda_0 \sin\theta\, ds}{r^2}$$

Substitute $rd\theta$ for ds:

$$dE = \frac{k\lambda_0 \sin\theta\, r d\theta}{r^2} = \frac{k\lambda_0 \sin\theta\, d\theta}{r}$$

Substitute for dE in equation (1) to obtain:

$$d\vec{E} = -\frac{k\lambda_0 \sin\theta \cos\theta\, d\theta}{r}\hat{i} - \frac{k\lambda_0 \sin^2\theta\, d\theta}{r}\hat{j}$$

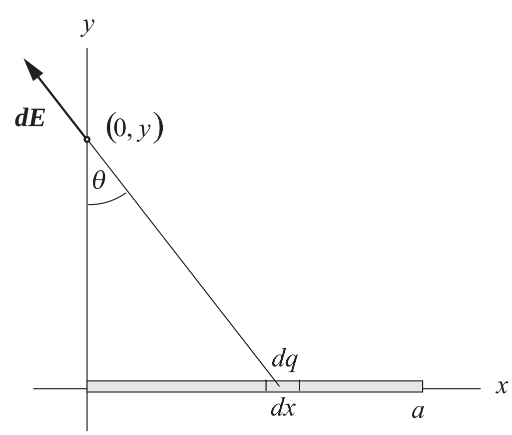
Integrate $d\vec{E}$ from $\theta = 0$ to 2π and simplify to obtain:

$$\vec{E} = -\frac{k\lambda_0}{2r}\int_0^{2\pi}\sin 2\theta\, d\theta\,\hat{i} - \frac{k\lambda_0}{r}\int_0^{2\pi}\sin^2\theta\, d\theta\,\hat{j} = 0 - \frac{\pi k\lambda_0}{r}\hat{j} = \boxed{-\frac{\pi k\lambda_0}{r}\hat{j}}$$

(*b*) The field at the origin is in the negative y direction and its magnitude is $\frac{\pi k\lambda_0}{r}$.

23 •• A line of charge that has uniform linear charge density λ lies on the x axis from $x = 0$ to $x = a$. Show that the y component of the electric field at a point on the y axis is given by $E_y = \frac{k\lambda}{y}\frac{a}{\sqrt{y^2 + a^2}}, \quad y \neq 0$.

Picture the Problem The line of charge and the point whose coordinates are (0, y) are shown in the diagram. Also shown is a segment of the line of length dx and charge dq. The field due to this charge at (0, y) is $d\vec{E}$. We can find dE_y from $d\vec{E}$ and then integrate from $x = 0$ to $x = a$ to find the y component of the electric field at a point on the y axis.



(*a*) Express the magnitude of the field $d\vec{E}$ due to charge dq of the element of length dx:

$$dE = \frac{kdq}{r^2}$$

where $r^2 = x^2 + y^2$

Because $dq = \lambda dx$:

$$dE = \frac{k\lambda dx}{x^2 + y^2}$$

Express the y component of dE:

$$dE_y = \frac{k\lambda}{x^2 + y^2}\cos\theta\, dx$$

Refer to the diagram to express $\cos\theta$ in terms of x and y:

$$\cos\theta = \frac{y}{\sqrt{x^2 + y^2}}$$

Substitute for $\cos\theta$ in the expression for dE_y to obtain:

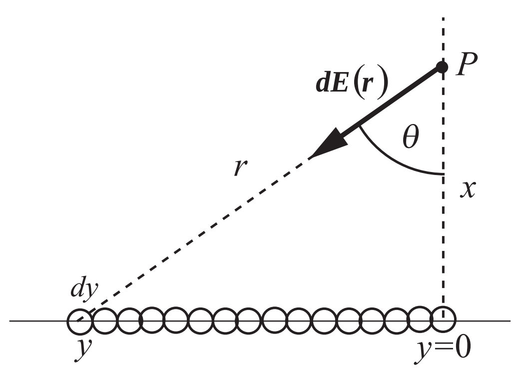
$$dE_y = \frac{k\lambda y}{\left(x^2 + y^2\right)^{3/2}}dx$$

Integrate from $x = 0$ to $x = a$ and simplify to obtain:

$$E_y = k\lambda y\int_0^a \frac{1}{\left(x^2 + y^2\right)^{3/2}}dx = k\lambda y\left[\frac{x}{y^2\sqrt{x^2 + y^2}}\right]_0^a = \boxed{\frac{k\lambda}{y}\frac{a}{\sqrt{a^2 + y^2}}}$$

24 ••• Calculate the electric field a distance z from a uniformly charged infinite flat non-conducting sheet by modeling the sheet as a continuum of infinite straight lines of charge.

Picture the Problem The field due to a line of charge is given by $E(r) = \frac{1}{2\pi\epsilon_0}\frac{\lambda}{r}$ where r is the perpendicular distance to the line. The diagram shows a point P, at which we will calculate the electric field due a continuum of infinite straight non-conducting lines of charge, and a few of the lines of charge. P is a distance L from the plane and the origin of the coordinate system is directly below P. Note that the horizontal components of the field at P, by symmetry, add up to zero. Hence we need only find the sum of all the z components of the field.



Because the horizontal components of the electric field add up to zero, the resultant field is given by:

$$E = E_{\perp} = \int_{-\pi/2}^{\pi/2} dE(r)\cos\theta \qquad (1)$$

Express the field due to an infinite line of charge:

$$dE(r)=\frac{1}{2\pi\in_0}\frac{d\lambda}{r}$$, where r is the perpendicular distance to the line of charge.

The surface charge density σ of the plane and the linear charge density of the charged rings λ are related:

$$d\lambda=\sigma\,dy$$

Substitute for $d\lambda$ to obtain:

$$dE(r)=\frac{1}{2\pi\in_0}\frac{\sigma\,dy}{r}$$

Substituting for $dE(r)$ in equation (1) yields:

$$E=\frac{1}{2\pi\in_0}\int_{-\pi/2}^{\pi/2}\frac{\sigma\,dy}{r}\cos\theta$$

Referring to the diagram, note that:

$$y=x\tan\theta\Rightarrow dy=x\sec^2\theta\,d\theta$$

Substitute for dy in the expression for E to obtain:

$$E=\frac{\sigma}{2\pi\in_0}\int_{-\pi/2}^{\pi/2}\frac{x\sec^2\theta\cos\theta\,d\theta}{r}$$

Because $x=r\cos\theta$:

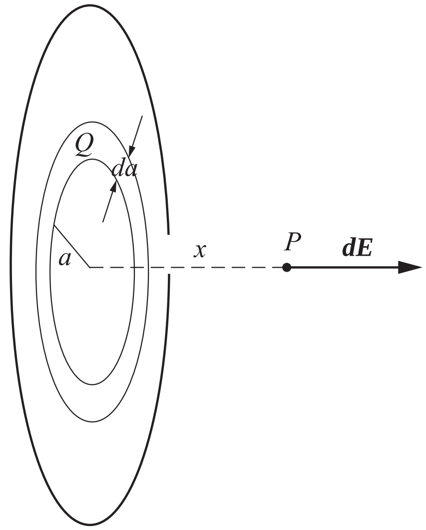
$$E_\perp=\frac{\sigma}{2\pi\in_0}\int_{-\pi/2}^{\pi/2}\sec^2\theta\cos^2\theta\,d\theta$$
$$=\frac{\sigma}{2\pi\in_0}\int_{-\pi/2}^{\pi/2}d\theta$$

Integrating this expression yields:

$$E=\frac{\sigma}{2\pi\in_0}\int_{-\pi/2}^{\pi/2}d\theta=\frac{\sigma}{2\pi\in_0}\pi=\boxed{\frac{\sigma}{2\in_0}}$$

25 •• [SSM] Calculate the electric field a distance z from a uniformly charged infinite flat non-conducting sheet by modeling the sheet as a continuum of infinite circular rings of charge.

Picture the Problem The field at a point on the axis of a uniformly charged ring lies along the axis and is given by Equation 22-8. The diagram shows one ring of the continuum of circular rings of charge. The radius of the ring is a and the distance from its center to the field point P is x. The ring has a uniformly distributed charge Q. The resultant electric field at P is the sum of the fields due to the continuum of circular rings. Note that, by symmetry, the horizontal components of the electric field cancel.



Express the field of a single uniformly charged ring with charge Q and radius a on the axis of the ring at a distance x away from the plane of the ring:

$$\vec{\boldsymbol{E}} = E_x \hat{\boldsymbol{i}} \text{ , where } E_x = \frac{kQx}{\left(x^2 + a^2\right)^{3/2}}$$

Substitute dq for Q and dE_x for E_x to obtain:

$$dE_x = \frac{kxdq}{\left(x^2 + a^2\right)^{3/2}}$$

The resultant electric field at P is the sum of the fields due to all the circular rings. Integrate both sides to calculate the resultant field for the entire plane. The field point remains fixed, so x is constant:

$$E = \int \frac{kxdq}{\left(x^2 + a^2\right)^{3/2}} = kx\int \frac{dq}{\left(x^2 + a^2\right)^{3/2}}$$

To evaluate this integral we change integration variables from q to a. The charge $dq = \sigma\, dA$ where $dA = 2\pi\, a\, da$ is the area of a ring of radius a and width da:

$$dq = 2\pi\sigma\, a\, da$$

so

$$E = kx\int_0^{\infty} \frac{2\pi\, \sigma\, a\, da}{\left(x^2 + a^2\right)^{3/2}}$$

$$= 2\pi\, \sigma\, kx\int_0^{\infty} \frac{a\, da}{\left(x^2 + a^2\right)^{3/2}}$$

To integrate this expression, let $u = \sqrt{x^2 + a^2}$. Then:

$$du = \tfrac{1}{2}\frac{1}{\sqrt{x^2 + a^2}}\left(2ada\right) = \frac{a}{u}da$$

or

$$ada = udu$$

Noting that when $a = 0$, $u = x$, substitute and simplify to obtain:

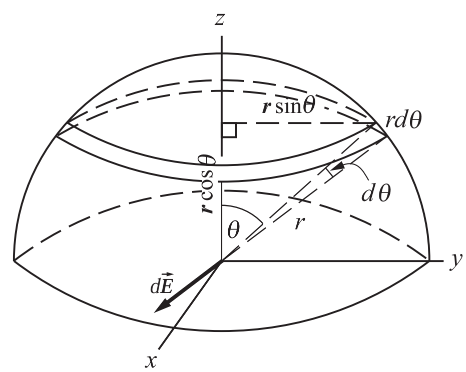
$$E = 2\pi\sigma kx\int_x^\infty \frac{u}{u^3}du = 2\pi\sigma kx\int_x^\infty u^{-2}du$$

Evaluating the integral yields:

$$E = 2\pi\sigma kx\left(-\frac{1}{u}\right)\Bigg|_x^\infty = 2\pi k\sigma = \boxed{\frac{\sigma}{2\in_0}}$$

26 ••• A thin hemispherical shell of radius R has a uniform surface charge σ. Find the electric field at the center of the base of the hemispherical shell.

Picture the Problem Consider the ring with its axis along the z direction shown in the diagram. Its radius is $z = r\cos\theta$ and its width is $rd\theta$. We can use the equation for the field on the axis of a ring charge and then integrate to express the field at the center of the hemispherical shell.



Express the field on the axis of the ring of charge:

$$dE = \frac{kzdq}{\left(r^2\sin^2\theta + r^2\cos^2\theta\right)^{3/2}} = \frac{kzdq}{r^3}$$

where $z = r\cos\theta$

Express the charge dq on the ring:

$$dq = \sigma dA = \sigma\left(2\pi r\sin\theta\right)rd\theta = 2\pi\sigma r^2\sin\theta d\theta$$

Substitute to obtain:

$$dE = \frac{k\left(r\cos\theta\right)2\pi\sigma r^2\sin\theta d\theta}{r^3} = 2\pi k\sigma\sin\theta\cos\theta d\theta$$

Integrating dE from $\theta = 0$ to $\pi/2$ yields:

$$E = 2\pi k\sigma\int_0^{\pi/2}\sin\theta\cos\theta d\theta = 2\pi k\sigma\left[\tfrac{1}{2}\sin^2\theta\right]_0^{\pi/2} = \boxed{\pi k\sigma}$$

Gauss's Law

27 • A square that has 10-cm-long edges is centered on the x axis in a region where there exists a uniform electric field given by $\vec{E} = (2.00\text{ kN/C})\hat{i}$. (a) What is the electric flux of this electric field through the surface of a square if the normal to the surface is in the $+x$ direction? (b) What is the electric flux through the same square surface if the normal to the surface makes a 60º angle with the y axis and an angle of 90° with the z axis?

Picture the Problem The definition of electric flux is $\phi = \oint_S \vec{E} \cdot \hat{n}\,dA$. We can apply this definition to find the electric flux through the square in its two orientations.

(a) Apply the definition of ϕ to find the flux of the field when the square is parallel to the yz plane:

$$\begin{aligned}\phi &= \oint_S (2.00\,\text{kN/C})\hat{i} \cdot \hat{i}\,dA \\ &= (2.00\,\text{kN/C})\oint_S dA \\ &= (2.00\,\text{kN/C})(0.100\,\text{m})^2 \\ &= \boxed{20.0\,\text{N}\cdot\text{m}^2/\text{C}}\end{aligned}$$

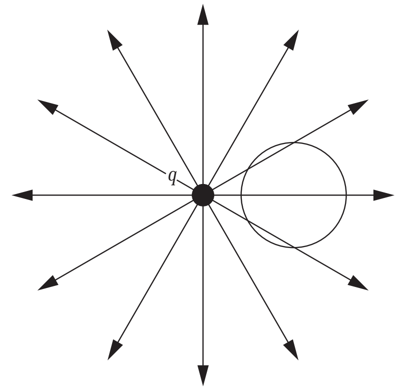
(b) Proceed as in (a) with $\hat{i} \cdot \hat{n} = \cos 30°$ to obtain:

$$\begin{aligned}\phi &= \oint_S (2.00\,\text{kN/C})\cos 30°\,dA \\ &= (2.00\,\text{kN/C})\cos 30° \oint_S dA \\ &= (2.00\,\text{kN/C})(0.100\,\text{m})^2 \cos 30° \\ &= \boxed{17\,\text{N}\cdot\text{m}^2/\text{C}}\end{aligned}$$

28 • A single point charge (q = +2.00 μC) is fixed at the origin. An imaginary spherical surface of radius 3.00 m is centered on the x axis at x = 5.00 m. (a) Sketch electric-field lines for this charge (in two dimensions) assuming twelve equally-spaced field lines in the xy plane leave the charge location, with one of the lines in the $+x$ direction. Do any lines enter the spherical surface? If so, how many? (b) Do any lines leave the spherical surface? If so, how many? (c) Counting the lines that enter as negative and the ones that leave as positive, what is the net number of field lines that penetrate the spherical surface? (d) What is the net electric flux through this spherical surface?

Determine the Concept We must show the twelve electric field lines originating at q and, in the absence of other charges, radially symmetric with respect to the location of q. While we're drawing twelve lines in this problem, the number of lines that we draw is always, by agreement, in proportion to the magnitude of q.

(*a*) The sketch of the field lines and of the spherical surface is shown in the diagram to the right.



Given the number of field lines drawn from *q,* 3 lines enter the spherical surface. Had we chosen to draw 24 field lines, 6 would have entered the spherical surface.

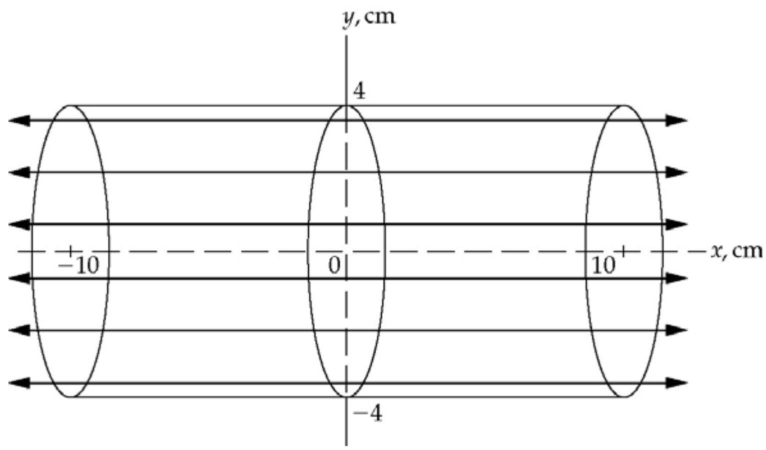
(*b*) Three lines leave the spherical surface.

(*c*) Because the three lines that enter the spherical surface also leave the spherical surface, the net number of field lines that pass through the surface is zero.

(*d*) Because as many field lines leave the spherical surface as enter it, the net flux is zero.

29 • [SSM] An electric field is given by $\vec{E} = \text{sign}(x)\cdot(300\text{ N/C})\hat{i}$, where sign($x$) equals –1 if $x < 0$, 0 if $x = 0$, and +1 if $x > 0$. A cylinder of length 20 cm and radius 4.0 cm has its center at the origin and its axis along the x axis such that one end is at $x = +10$ cm and the other is at $x = -10$ cm. (*a*) What is the electric flux through each end? (*b*) What is the electric flux through the curved surface of the cylinder? (*c*) What is the electric flux through the entire closed surface? (*d*) What is the net charge inside the cylinder?

Picture the Problem The field at both circular faces of the cylinder is parallel to the outward vector normal to the surface, so the flux is just *EA*. There is no flux through the curved surface because the normal to that surface is perpendicular to $\vec{E}$. The net flux through the closed surface is related to the net charge inside by Gauss's law.



(a) Use Gauss's law to calculate the flux through the right circular surface:

$$\phi_{\text{right}} = \vec{E}_{\text{right}} \cdot \hat{n}_{\text{right}} A = (300\,\text{N/C})\hat{i} \cdot \hat{i}(\pi)(0.040\,\text{m})^2 = \boxed{1.5\,\text{N}\cdot\text{m}^2/\text{C}}$$

Apply Gauss's law to the left circular surface to obtain:

$$\phi_{\text{left}} = \vec{E}_{\text{left}} \cdot \hat{n}_{\text{left}} A = (-300\,\text{N/C})\hat{i} \cdot (-\hat{i})(\pi)(0.040\,\text{m})^2 = \boxed{1.5\,\text{N}\cdot\text{m}^2/\text{C}}$$

(b) Because the field lines are parallel to the curved surface of the cylinder:

$$\phi_{\text{curved}} = \boxed{0}$$

(c) Express and evaluate the net flux through the entire cylindrical surface:

$$\phi_{\text{net}} = \phi_{\text{right}} + \phi_{\text{left}} + \phi_{\text{curved}} = 1.5\,\text{N}\cdot\text{m}^2/\text{C} + 1.5\,\text{N}\cdot\text{m}^2/\text{C} + 0 = \boxed{3.0\,\text{N}\cdot\text{m}^2/\text{C}}$$

(d) Apply Gauss's law to obtain:

$$\phi_{\text{net}} = 4\pi k Q_{\text{inside}} \Rightarrow Q_{\text{inside}} = \frac{\phi_{\text{net}}}{4\pi k}$$

Substitute numerical values and evaluate Q_{inside}:

$$Q_{\text{inside}} = \frac{3.0\,\text{N}\cdot\text{m}^2/\text{C}}{4\pi\left(8.988\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2\right)} = \boxed{2.7\times10^{-11}\,\text{C}}$$

30 • Careful measurement of the electric field at the surface of a black box indicates that the net outward electric flux through the surface of the box is 6.0 kN·m^2/C. (*a*) What is the net charge inside the box? (*b*) If the net outward electric flux through the surface of the box were zero, could you conclude that there were no charges inside the box? Explain your answer.

Picture the Problem We can use Gauss's law to find the net charge inside the box.

(*a*) Apply Gauss's law in terms of ϵ_0 to find the net charge inside the box:

$$\phi_{\text{net}} = \frac{Q_{\text{inside}}}{\epsilon_0} \Rightarrow Q_{\text{inside}} = \epsilon_0\, \phi_{\text{net}}$$

Substitute numerical values and evaluate Q_{inside}:

$$Q_{\text{inside}} = \left(8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(6.0\,\frac{\text{kN}\cdot\text{m}^2}{\text{C}}\right) = \boxed{5.3\times10^{-8}\ \text{C}}$$

(*b*) You can only conclude that the net charge is zero. There may be an equal number of positive and negative charges present inside the box.

31 • A point charge ($q = +2.00\ \mu$C) is at the center of an imaginary sphere that has a radius equal to 0.500 m. (*a*) Find the surface area of the sphere. (*b*) Find the magnitude of the electric field at all points on the surface of the sphere. (*c*) What is the flux of the electric field through the surface of the sphere? (*d*) Would your answer to Part (*c*) change if the point charge were moved so that it was inside the sphere but not at its center? (*e*) What is the flux of the electric field through the surface of an imaginary cube that has 1.00-m-long edges and encloses the sphere?

Picture the Problem We can apply Gauss's law to find the flux of the electric field through the surface of the sphere.

(*a*) Use the formula for the surface area of a sphere to obtain:

$$A = 4\pi r^2 = 4\pi(0.500\,\text{m})^2 = 3.142\,\text{m}^2 = \boxed{3.14\,\text{m}^2}$$

(*b*) Apply Coulomb's law to find *E*:

$$E = \frac{1}{4\pi\,\epsilon_0}\frac{q}{r^2} = \frac{1}{4\pi\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}\frac{2.00\,\mu\text{C}}{(0.500\,\text{m})^2} = 7.190\times10^4\ \text{N/C}$$
$$= \boxed{7.19\times10^4\ \text{N/C}}$$

(*c*) Apply Gauss's law to obtain:

$$\phi = \oint_S \vec{\boldsymbol{E}} \cdot \hat{\boldsymbol{n}}dA = \oint_S EdA$$
$$= \left(7.190\times10^4\ \text{N/C}\right)\left(3.142\,\text{m}^2\right)$$
$$= \boxed{2.26\times10^5\ \text{N}\cdot\text{m}^2/\text{C}}$$

(*d*) No. The flux through the surface is independent of where the charge is located inside the sphere.

(*e*) Because the cube encloses the sphere, the flux through the surface of the sphere will also be the flux through the cube:

$$\phi_{\text{cube}} = \boxed{2.26\times10^5\ \text{N}\cdot\text{m}^2/\text{C}}$$

32 • What is the electric flux through one side of a cube that has a single point charge of –3.00 μC placed at its center? *HINT: You do not need to integrate any equations to get the answer.*

Picture the Problem The flux through the cube is given by $\phi_{\text{net}} = Q_{\text{inside}}/\in_0$, where Q_{inside} is the charge at the center of the cube. The flux through one side of the cube is one-sixth of the total flux through the cube.

The flux through one side of the cube is one-sixth of the total flux through the cube:

$$\phi_{1\text{ face}} = \tfrac{1}{6}\phi_{\text{tot}} = \frac{Q}{6\in_0}$$

Substitute numerical values and evaluate $\phi_{1\text{ face}}$:

$$\phi_{1\text{ face}} = \frac{-3.00\,\mu\text{C}}{6\left(8.854\times10^{-12}\ \dfrac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)}$$
$$= \boxed{-5.65\times10^4\ \frac{\text{N}\cdot\text{m}^2}{\text{C}}}$$

33 • **[SSM]** A single point charge is placed at the center of an imaginary cube that has 20-cm-long edges. The electric flux out of one of the cube's sides is –1.50 kN·m^2/C. How much charge is at the center?

Picture the Problem The net flux through the cube is given by $\phi_{\text{net}} = Q_{\text{inside}}/\in_0$, where Q_{inside} is the charge at the center of the cube.

The flux through one side of the cube is one-sixth of the total flux through the cube:

$$\phi_{1\text{ faces}} = \tfrac{1}{6}\phi_{\text{net}} = \frac{Q_{\text{inside}}}{6\in_0}$$

Solving for Q_{inside} yields: $Q_{\text{inside}} = 6\in_0 \phi_{\text{2 faces}}$

Substitute numerical values and evaluate Q_{inside}:

$$Q_{\text{inside}} = 6\left(8.854\times10^{-12}\ \frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(-1.50\frac{\text{kN}\cdot\text{m}^2}{\text{C}^2}\right) = \boxed{-79.7\ \text{nC}}$$

34 •• Because the formulas for Newton's law of gravity and for Coulomb's law have the same inverse-square dependence on distance, a formula analogous to the formula for Gauss's law can be found for gravity. The gravitational field $\vec{g}$ at a location is the force per unit mass on a test mass m_0 placed at that location. Then, for a point mass m at the origin, the gravitational field $\vec{g}$ at some position $\vec{r}$ is $\vec{g} = \left(Gm/r^2\right)\hat{r}$. Compute the flux of the gravitational field through a spherical surface of radius R centered at the origin, and verify that the gravitational analog of Gauss's law is $\phi_{\text{net}} = -4\pi Gm_{\text{inside}}$.

Picture the Problem We'll define the flux of the gravitational field in a manner that is analogous to the definition of the flux of the electric field and then substitute for the gravitational field and evaluate the integral over the closed spherical surface.

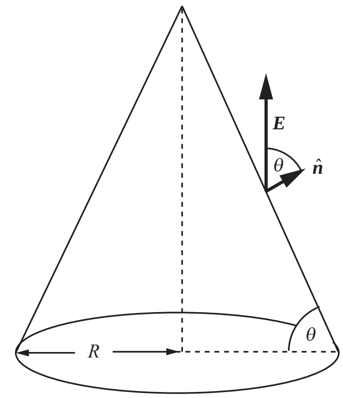
Define the gravitational flux as: $\phi_{\text{g}} = \oint_S \vec{g}\cdot\hat{n}dA$

Substitute for $\vec{g}$ and evaluate the integral to obtain:

$$\begin{aligned}\phi_{\text{net}} &= \oint_S\left(-\frac{Gm_{\text{inside}}}{r^2}\hat{r}\right)\cdot\hat{n}dA\\ &= -\frac{Gm_{\text{inside}}}{r^2}\oint_S dA\\ &= \left(-\frac{Gm_{\text{inside}}}{r^2}\right)\left(4\pi r^2\right)\\ &= \boxed{-4\pi Gm_{\text{inside}}}\end{aligned}$$

35 •• An imaginary right circular cone (Figure 22-40) that has a base angle θ and a base radius R is in a charge free region that has a uniform electric field $\vec{E}$ (field lines are vertical and parallel to the cone's axis). What is the ratio of the number of field lines per unit area penetrating the base to the number of field lines per unit area penetrating the conical surface of the cone? Use Gauss's law in your answer. (The field lines in the figure are only a representative sample.)

Picture the Problem Because the cone encloses no charge, we know, from Gauss's law, that the net flux of the electric field through the cone's surface is zero. Thus, the number of field lines penetrating the curved surface of the cone must equal the number of field lines penetrating the base and the entering flux must equal the exiting flux.



The flux penetrating the base of the cone is given by:

$$\phi_{\text{entering}} = EA_{\text{base}}$$

The flux penetrating the curved surface of the cone is given by:

$$\phi_{\text{exiting}} = \oint_S \vec{E}\cdot\hat{n}\,dA = \oint_S E\cos\theta\,dA$$

Equating the fluxes and simplifying yields:

$$A_{\text{base}} = \cos\theta\oint_S dA = (\cos\theta)A_{\substack{\text{curved}\\\text{surface}}}$$

The ratio of the density of field lines is:

$$\frac{A_{\text{base}}}{A_{\substack{\text{curved}\\\text{surface}}}} = \boxed{\cos\theta}$$

36 •• In the atmosphere and at an altitude of 250 m, you measure the electric field to be 150 N/C directed downward and you measure the electric field to be 170 N/C directed downward at an altitude of 400 m. Calculate the volume charge density of the atmosphere in the region between altitudes of 250 m and 400 m, assuming it to be uniform. (You may neglect the curvature of Earth. Why?)

Picture the Problem We'll model this portion of Earth's atmosphere as though it is a cylinder with cross-sectional area A and height h. Because the electric flux increases with altitude, we can conclude that there is charge inside the cylindrical region and use Gauss's law to find that charge and hence the charge density of the atmosphere in this region.

The definition of volume charge density is:

$$\rho = \frac{Q}{V}$$

Express the charge inside a cylinder of base area A and height h for a charge density ρ:

$$Q = \rho Ah$$

Taking upward to be the positive direction, apply Gauss's law to the charge in the cylinder:

$Q = -(E_h A - E_0 A)\epsilon_0 = (E_0 A - E_h A)\epsilon_0$

where we've taken our zero at 250 m above the surface of a flat Earth.

Substitute to obtain:

$$\rho = \frac{(E_0 A - E_h A)\epsilon_0}{Ah} = \frac{(E_0 - E_h)\epsilon_0}{h}$$

Substitute numerical values and evaluate ρ:

$$\rho = \frac{(150\,\text{N/C} - 170\,\text{N/C})(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)}{400\,\text{m} - 250\,\text{m}} = \boxed{-1.2\times10^{-12}\ \text{C/m}^3}$$

where we've been able to neglect the curvature of Earth because the maximum height of 400 m is approximately 0.006% of the radius of Earth and because the diameter of the cylindrical Gaussian surface can be arbitrarily small.

Gauss's Law Applications in Spherical Symmetry Situations

37 • A thin non-conducting spherical shell of radius R_1 has a total charge q_1 that is uniformly distributed on its surface. A second, larger thin non-conducting spherical shell of radius R_2 that is coaxial with the first has a charge q_2 that is uniformly distributed on its surface. (*a*) Use Gauss's law to obtain expressions for the electric field in each of the three regions: $r < R_1$, $R_1 < r < R_2$, and $r > R_2$. (*b*) What should the ratio of the charges q_1/q_2 and the relative signs for q_1 and q_2 be for the electric field to be zero throughout the region $r > R_2$? (*c*) Sketch the electric field lines for the situation in Part (*b*) when q_1 is positive.

Picture the Problem To find E_n in these three regions we can choose Gaussian surfaces of appropriate radii and apply Gauss's law. On each of these surfaces, E_r is constant and Gauss's law relates E_r to the total charge inside the surface.

(*a*) Use Gauss's law to find the electric field in the region $r < R_1$:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}}$$

and

$\vec{E}_{r<R_1} = \dfrac{Q_{\text{inside}}}{\epsilon_0 A}\hat{r}$ where $\hat{r}$ is a unit radial vector.

Because $Q_{\text{inside}} = 0$:

$$\vec{E}_{r<R_1} = \boxed{0}$$

Apply Gauss's law in the region $R_1 < r < R_2$:

$$\vec{E}_{R_1<r<R_1} = \frac{q_1}{\epsilon_0 (4\pi r^2)}\hat{r} = \boxed{\frac{kq_1}{r^2}\hat{r}}$$

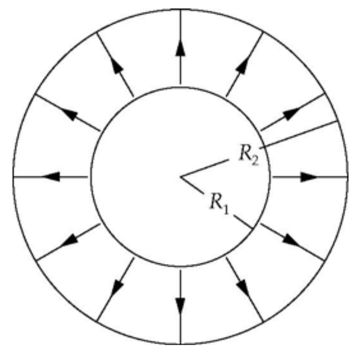
Using Gauss's law, find the electric field in the region $r > R_2$:

$$\vec{E}_{r>R_2} = \frac{q_1 + q_2}{\epsilon_0 \left(4\pi r^2\right)}\hat{r} = \boxed{\frac{k\left(q_1 + q_2\right)}{r^2}\hat{r}}$$

(*b*) Set $E_{r>R_2} = 0$ to obtain:

$$q_1 + q_2 = 0 \Rightarrow \frac{q_1}{q_2} = \boxed{-1}$$

(*c*) The electric field lines for the situation in (*b*) with q_1 positive is shown to the right.



38 • A spherical shell of radius 6.00 cm carries a uniform surface charge density of A non-conducting thin spherical shell of radius 6.00 cm has a uniform surface charge density of 9.00 nC/m^2. (*a*) What is the total charge on the shell? Find the electric field at the following distances from the sphere's center: (*b*) 2.00 cm, (*c*) 5.90 cm, (*d*) 6.10 cm, and (*e*) 10.0 cm.

Picture the Problem We can use the definition of surface charge density and the formula for the area of a sphere to find the total charge on the shell. Because the charge is distributed uniformly over a spherical shell, we can choose a spherical Gaussian surface and apply Gauss's law to find the electric field as a function of the distance from the center of the spherical shell.

(*a*) Using the definition of surface charge density, relate the charge on the sphere to its area:

$$Q = \sigma A = 4\pi\sigma r^2$$

Substitute numerical values and evaluate Q:

$$Q = 4\pi\left(9.00\,\text{nC/m}^2\right)\left(0.0600\,\text{m}\right)^2$$
$$= 0.4072\,\text{nC} = \boxed{0.407\,\text{nC}}$$

Apply Gauss's law to a spherical surface of radius r that is concentric the spherical shell to obtain:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 4\pi r^2 E_n = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Noting that, due to symmetry, $E_r = E_n$, solve for E_r to obtain:

$$E_r = \frac{Q_{\text{inside}}}{4\pi \in_0} \frac{1}{r^2} = \frac{kQ_{\text{inside}}}{r^2}$$

(*b*) The charge inside a sphere whose radius is 2.00 cm is zero and hence:

$$E_{r=2.00\,\text{cm}} = \boxed{0}$$

(*c*) The charge inside a sphere whose radius is 5.90 cm is zero and hence:

$$E_{r=5.90\,\text{cm}} = \boxed{0}$$

(*d*) The charge inside a sphere whose radius is 6.10 cm is 0.4072 nC and hence:

$$E_{r=6.10\,\text{cm}} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(0.4072\,\text{nC}\right)}{\left(0.0610\,\text{m}\right)^2} = \boxed{983\,\text{N/C}}$$

(*e*) The charge inside a sphere whose radius is 10.0 cm is 0.4072 nC and hence:

$$E_{r=10\,\text{cm}} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(0.4072\,\text{nC}\right)}{\left(0.100\,\text{m}\right)^2} = \boxed{366\,\text{N/C}}$$

39 •• [SSM] A non-conducting sphere of radius 6.00 cm has a uniform volume charge density of 450 nC/m^3. (*a*) What is the total charge on the sphere? Find the electric field at the following distances from the sphere's center: (*b*) 2.00 cm, (*c*) 5.90 cm, (*d*) 6.10 cm, and (*e*) 10.0 cm.

Picture the Problem We can use the definition of volume charge density and the formula for the volume of a sphere to find the total charge of the sphere. Because the charge is distributed uniformly throughout the sphere, we can choose a spherical Gaussian surface and apply Gauss's law to find the electric field as a function of the distance from the center of the sphere.

(*a*) Using the definition of volume charge density, relate the charge on the sphere to its volume:

$$Q = \rho V = \tfrac{4}{3}\pi\rho r^3$$

Substitute numerical values and evaluate Q:

$$Q = \tfrac{4}{3}\pi\left(450\,\text{nC/m}^3\right)\left(0.0600\,\text{m}\right)^3 = 0.4072\,\text{nC} = \boxed{0.407\,\text{nC}}$$

Apply Gauss's law to a spherical surface of radius $r < R$ that is concentric with the spherical shell to obtain:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 4\pi r^2 E_n = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Noting that, due to symmetry, $E_n = E_r$, solve for E_r to obtain:

$$E_r = \frac{Q_{\text{inside}}}{4\pi \epsilon_0} \frac{1}{r^2} = \frac{kQ_{\text{inside}}}{r^2}$$

Because the charge distribution is uniform, we can find the charge inside the Gaussian surface by using the definition of volume charge density to establish the proportion:

$$\frac{Q}{V} = \frac{Q_{\text{inside}}}{V'}$$

where V' is the volume of the Gaussian surface.

Solve for Q_{inside} to obtain:

$$Q_{\text{inside}} = Q\frac{V'}{V} = Q\frac{r^3}{R^3}$$

Substitute for Q_{inside} to obtain:

$$E_{r<R} = \frac{Q_{\text{inside}}}{4\pi \epsilon_0} \frac{1}{r^2} = \frac{kQ}{R^3} r$$

(b) Evaluate $E_{r = 2.00\text{ cm}}$:

$$E_{r=2.00\,\text{cm}} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(0.4072\,\text{nC}\right)}{\left(0.0600\,\text{m}\right)^3}\left(0.0200\,\text{m}\right) = \boxed{339\,\text{N/C}}$$

(c) Evaluate $E_{r = 5.90\text{ cm}}$:

$$E_{r=5.90\,\text{cm}} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(0.4072\,\text{nC}\right)}{\left(0.0600\,\text{m}\right)^3}\left(0.0590\,\text{m}\right) = \boxed{1.00\,\text{kN/C}}$$

Apply Gauss's law to the Gaussian surface with $r > R$:

$$4\pi r^2 E_r = \frac{Q_{\text{inside}}}{\epsilon_0} \Rightarrow E_r = \frac{kQ_{\text{inside}}}{r^2} = \frac{kQ}{r^2}$$

(d) Evaluate $E_{r = 6.10\text{ cm}}$:

$$E_{r=6.10\,\text{cm}} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(0.4072\,\text{nC}\right)}{\left(0.0610\,\text{m}\right)^2} = \boxed{983\,\text{N/C}}$$

(e) Evaluate $E_{r\,=\,10.0\text{ cm}}$:

$$E_{r=10.0\,\text{cm}} = \frac{\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(0.4072\,\text{nC}\right)}{\left(0.100\,\text{m}\right)^2} = \boxed{366\,\text{N/C}}$$

40 •• Consider the solid conducting sphere and the concentric conducting spherical shell in Figure 22-41. The spherical shell has a charge –7*Q*. The solid sphere has a charge +2*Q*. (*a*) How much charge is on the outer surface and how much charge is on the inner surface of the spherical shell? (*b*) Suppose a metal wire is now connected between the solid sphere and the shell. After electrostatic equilibrium is re-established, how much charge is on the solid sphere and on each surface of the spherical shell? Does the electric field at the surface of the solid sphere change when the wire is connected? If so, in what way? (*c*) Suppose we return to the conditions in Part (*a*), with +2*Q* on the solid sphere and –7*Q* on the spherical shell. We next connect the solid sphere to ground with a metal wire, and then disconnect it. Then how much total charge is on the solid sphere and on each surface of the spherical shell?

Determine the Concept The charges on a conducting sphere, in response to the repulsive Coulomb forces each experiences, will separate until electrostatic equilibrium conditions exit. The use of a wire to connect the two spheres or to ground the outer sphere will cause additional redistribution of charge.

(*a*) Because the outer sphere is conducting, the field in the thin shell must vanish. Therefore, $-2Q$, uniformly distributed, resides on the inner surface, and $-5Q$, uniformly distributed, resides on the outer surface.

(*b*) Now there is no charge on the inner surface and $-5Q$ on the outer surface of the spherical shell. The electric field just outside the surface of the inner sphere changes from a finite value to zero.

(*c*) In this case, the $-5Q$ is drained off, leaving no charge on the outer surface and $-2Q$ on the inner surface. The total charge on the outer sphere is then $-2Q$.

41 •• A non-conducting solid sphere of radius 10.0 cm has a uniform volume charge density. The magnitude of the electric field at 20.0 cm from the sphere's center is 1.88×10^3 N/C. (*a*) What is the sphere's volume charge density? (*b*) Find the magnitude of the electric field at a distance of 5.00 cm from the sphere's center.

Picture the Problem (*a*) We can use the definition of volume charge density, in conjunction with Equation 22-18a, to find the sphere's volume charge density.
(*b*) We can use Equation 22-18b, in conjunction with our result from Part (*a*), to find the electric field at a distance of 5.00 cm from the solid sphere's center.

(*a*) The solid sphere's volume charge density is the ratio of its charge to its volume:

$$\rho = \frac{Q_{\text{inside}}}{V} = \frac{Q_{\text{inside}}}{\frac{4}{3}\pi R^3} \qquad (1)$$

For $r \geq R$, Equation 22-18*a* gives the electric field at a distance r from the center of the sphere:

$$E_{\text{r}} = \frac{1}{4\pi \in_0} \frac{Q_{\text{inside}}}{r^2} \qquad (2)$$

Solving for Q_{inside} yields:

$$Q_{\text{inside}} = 4\pi \in_0 E_{\text{r}} r^2$$

Substitute for Q_{inside} in equation (1) and simplify to obtain:

$$\rho = \frac{4\pi \in_0 E_{\text{r}} r^2}{\frac{4}{3}\pi R^3} = \frac{3 \in_0 E_{\text{r}} r^2}{R^3}$$

Substitute numerical values and evaluate ρ:

$$\rho = \frac{3\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(1.88\times10^3\ \text{N/C}\right)\left(20.0\ \text{cm}\right)^2}{\left(10.0\ \text{cm}\right)^3} = 1.997\,\mu\text{C/m}^3$$

$$= \boxed{2.00\,\mu\text{C/m}^3}$$

(*b*) For $r \leq R$, the electric field at a distance r from the center of the sphere is given by:

$$E_r = \frac{1}{4\pi \in_0} \frac{Q_{\text{inside}}}{R^3} r \qquad (3)$$

Express Q_{inside} for $r \leq R$:

$$Q_{\text{inside}} = \rho V_{\substack{\text{sphere whose}\\ \text{radius is } r}} = \tfrac{4}{3}\pi r^3 \rho$$

Substituting for Q_{inside} in equation (3) and simplifying yields:

$$E_r = \frac{1}{4\pi \in_0} \frac{\frac{4}{3}\pi r^3 \rho}{R^3} r = \frac{\rho r^4}{3 \in_0 R^3}$$

Substitute numerical values and evaluate $E_{r\,=\,5.00\ \text{cm}}$:

$$E_{r=5.00\,\text{cm}} = \frac{\left(1.997\,\mu\text{C/m}^3\right)\left(5.00\ \text{cm}\right)^4}{3\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(10.0\ \text{cm}\right)^3} = \boxed{470\ \text{N/C}}$$

42 •• A non-conducting solid sphere of radius R has a volume charge density that is proportional to the distance from the center. That is, $\rho = Ar$ for $r \leq R$, where A is a constant. (*a*) Find the total charge on the sphere. (*b*) Find the expressions for the electric field inside the sphere ($r < R$) and outside the sphere ($r > R$). (*c*) Sketch the magnitude of the electric field as a function of the distance r from the sphere's center.

Picture the Problem We can find the total charge on the sphere by expressing the charge dq in a spherical shell and integrating this expression between $r = 0$ and $r = R$. By symmetry, the electric fields must be radial. To find E_r inside the charged sphere we choose a spherical Gaussian surface of radius $r < R$. To find E_r outside the charged sphere we choose a spherical Gaussian surface of radius $r > R$. On each of these surfaces, E_r is constant. Gauss's law then relates E_r to the total charge inside the surface.

(*a*) Express the charge dq in a shell of thickness dr and volume $4\pi r^2\,dr$:

$$dq = 4\pi r^2 \rho dr = 4\pi r^2 (Ar)dr = 4\pi A r^3 dr$$

Integrate this expression from $r = 0$ to R to find the total charge on the sphere:

$$Q = 4\pi A\int_0^R r^3 dr = \left[\pi A r^4\right]_0^R = \boxed{\pi A R^4}$$

(*b*) Apply Gauss's law to a spherical surface of radius $r > R$ that is concentric with the nonconducting sphere to obtain:

$$\oint_S E_r dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 4\pi r^2 E_r = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Solving for E_r yields:

$$E_{r>R} = \frac{Q_{\text{inside}}}{4\pi\epsilon_0}\frac{1}{r^2} = \frac{kQ_{\text{inside}}}{r^2} = \frac{kA\pi R^4}{r^2} = \boxed{\frac{AR^4}{4\epsilon_0 r^2}}$$

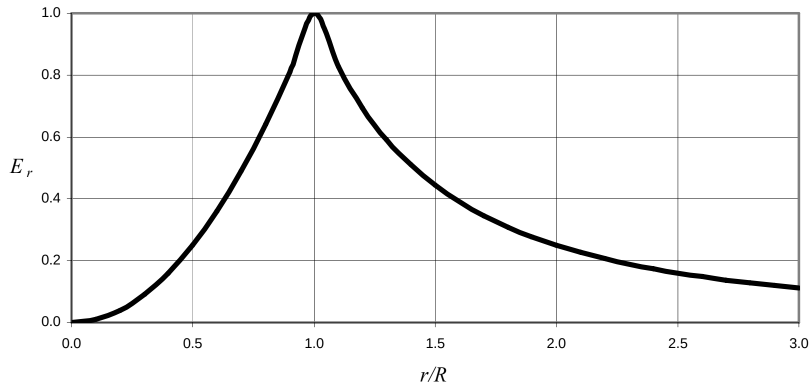
Apply Gauss's law to a spherical surface of radius $r < R$ that is concentric with the nonconducting sphere to obtain:

$$\oint_S E_r dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 4\pi r^2 E_r = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Solve for E_r and simplify to obtain:

$$E_{r<R} = \frac{Q_{\text{inside}}}{4\pi r^2\epsilon_0} = \frac{\pi A r^4}{4\pi r^2\epsilon_0} = \boxed{\frac{Ar^2}{4\epsilon_0}}$$

(c) The following graph of E_r versus r/R, with E_r in units of $A/(4\epsilon_0)$, was plotted using a spreadsheet program.



Remarks: Note that the results for (*a*) and (*b*) agree at *r* = *R*.

43 •• [SSM] A sphere of radius R has volume charge density $\rho = B/r$ for $r < R$, where B is a constant and $\rho = 0$ for $r > R$. (a) Find the total charge on the sphere. (b) Find the expressions for the electric field inside and outside the charge distribution (c) Sketch the magnitude of the electric field as a function of the distance r from the sphere's center.

Picture the Problem We can find the total charge on the sphere by expressing the charge dq in a spherical shell and integrating this expression between $r = 0$ and $r = R$. By symmetry, the electric fields must be radial. To find E_r inside the charged sphere we choose a spherical Gaussian surface of radius $r < R$. To find E_r outside the charged sphere we choose a spherical Gaussian surface of radius $r > R$. On each of these surfaces, E_r is constant. Gauss's law then relates E_r to the total charge inside the surface.

(a) Express the charge dq in a shell of thickness dr and volume $4\pi r^2\,dr$:

$$dq = 4\pi r^2 \rho dr = 4\pi r^2 \frac{B}{r} dr$$
$$= 4\pi B r dr$$

Integrate this expression from $r = 0$ to R to find the total charge on the sphere:

$$Q == 4\pi B \int_0^R r dr = \left[2\pi B r^2\right]_0^R$$
$$= \boxed{2\pi B R^2}$$

(b) Apply Gauss's law to a spherical surface of radius $r > R$ that is concentric with the nonconducting sphere to obtain:

$$\oint_S E_r dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \text{ or } 4\pi r^2 E_r = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Solving for E_r yields:

$$E_{r>R}=\frac{Q_{\text{inside}}}{4\pi\in_0}\frac{1}{r^2}=\frac{kQ_{\text{inside}}}{r^2}$$
$$=\frac{k2\pi BR^2}{r^2}=\boxed{\frac{BR^2}{2\in_0 r^2}}$$

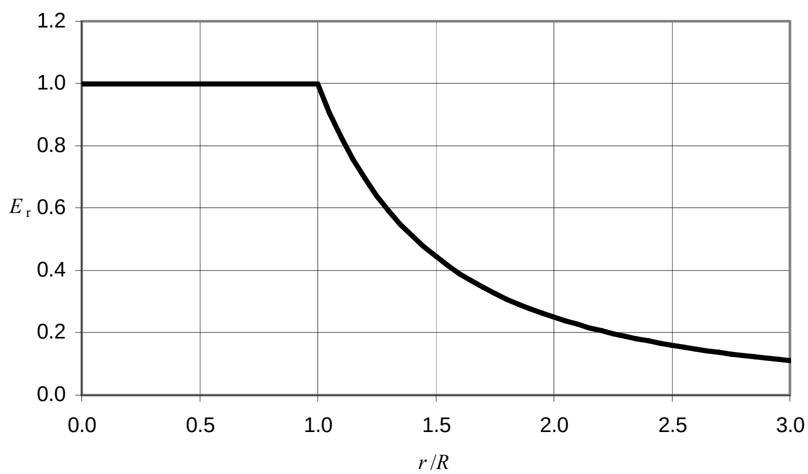
Apply Gauss's law to a spherical surface of radius $r < R$ that is concentric with the nonconducting sphere to obtain:

$$\oint_S E_r dA=\frac{1}{\in_0}Q_{\text{inside}}\Rightarrow 4\pi r^2 E_r=\frac{Q_{\text{inside}}}{\in_0}$$

Solving for E_r yields:

$$E_{r<R}=\frac{Q_{\text{inside}}}{4\pi r^2\in_0}=\frac{2\pi Br^2}{4\pi r^2\in_0}=\boxed{\frac{B}{2\in_0}}$$

(*c*) The following graph of E_r versus r/R, with E_r in units of $B/(2\in_0)$, was plotted using a spreadsheet program.



Remarks: Note that our results for (*a*) and (*b*) agree at *r* = *R*.

44 •• A sphere of radius R has volume charge density $\rho = C/r^2$ for $r < R$, where C is a constant and $\rho = 0$ for $r > R$. (*a*) Find the total charge on the sphere. (*b*) Find the expressions for the electric field inside and outside the charge distribution (*c*) Sketch the magnitude of the electric field as a function of the distance r from the sphere's center.

Picture the Problem We can find the total charge on the sphere by expressing the charge dq in a spherical shell and integrating this expression between $r = 0$ and $r = R$. By symmetry, the electric fields must be radial. To find E_r inside the charged sphere we choose a spherical Gaussian surface of radius $r < R$. To find E_r outside the charged sphere we choose a spherical Gaussian surface of radius $r > R$.

On each of these surfaces, E_r is constant. Gauss's law then relates E_r to the total charge inside the surface.

(*a*) Express the charge dq in a shell of thickness dr and volume $4\pi r^2\,dr$:

$$dq = 4\pi r^2 \rho dr = 4\pi r^2 \frac{C}{r^2} dr = 4\pi C dr$$

Integrate this expression from $r = 0$ to R to find the total charge on the sphere:

$$Q = 4\pi C \int_0^R dr = \left[4\pi Cr\right]_0^R = \boxed{4\pi CR}$$

(*b*) Apply Gauss's law to a spherical surface of radius $r > R$ that is concentric with the nonconducting sphere to obtain:

$$\oint_S E_r dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 4\pi r^2 E_r = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Solving for E_r yields:

$$E_{r>R} = \frac{Q_{\text{inside}}}{4\pi \epsilon_0} \frac{1}{r^2} = \frac{kQ_{\text{inside}}}{r^2} = \frac{k4\pi CR}{r^2} = \boxed{\frac{CR}{\epsilon_0 r^2}}$$

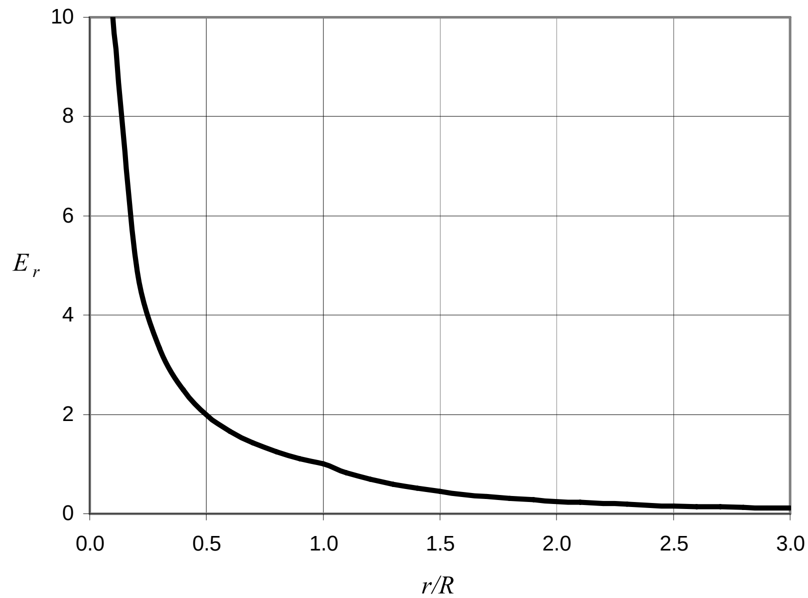
Apply Gauss's law to a spherical surface of radius $r < R$ that is concentric with the nonconducting sphere to obtain:

$$\oint_S E_r dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \text{ or } 4\pi r^2 E_r = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Solving for E_r yields:

$$E_{r<R} = \frac{Q_{\text{inside}}}{4\pi r^2 \epsilon_0} = \frac{4\pi Cr}{4\pi r^2 \epsilon_0} = \boxed{\frac{C}{\epsilon_0 r}}$$

(c) The following graph of E_r versus r/R, with E_r in units of $C/(\epsilon_0 R)$, was plotted using a spreadsheet program.



45 ••• A non-conducting spherical shell of inner radius R_1 and outer radius R_2 has a uniform volume charge density ρ. (a) Find the total charge on the shell. (b) Find expressions for the electric field everywhere.

Picture the Problem By symmetry, the electric fields resulting from this charge distribution must be radial. To find E_r for $r < R_1$ we choose a spherical Gaussian surface of radius $r < R_1$. To find E_r for $R_1 < r < R_2$ we choose a spherical Gaussian surface of radius $R_1 < r < R_2$. To find E_r for $r > R_2$ we choose a spherical Gaussian surface of radius $r > R_2$. On each of these surfaces, E_r is constant. Gauss's law then relates E_r to the total charge inside the surface.

(a) The charge in an infinitesimal spherical shell of radius r and thickness dr is:

$$dQ = \rho dV = 4\pi\rho r^2 dr$$

Integrate dQ from $r = R_1$ to R_2 to find the total charge in the spherical shell in the interval $R_1 < r < R_2$:

$$Q_{\text{total}} = 4\pi\rho\int_{R_1}^{R_2} r^2 dr = \left[\frac{4\pi C r^3}{3}\right]_{R_1}^{R_2}$$

$$= \boxed{\frac{4\pi\rho}{3}\left(R_2^3 - R_1^3\right)}$$

(*b*) Apply Gauss's law to a spherical surface of radius *r* that is concentric with the nonconducting spherical shell to obtain:

$$\oint_S E_r dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 4\pi r^2 E_r = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Solving for E_r yields:

$$E_r = \frac{Q_{\text{inside}}}{4\pi \epsilon_0} \frac{1}{r^2} = \frac{kQ_{\text{inside}}}{r^2}$$

Evaluate $E_{r<R_1}$:

$$E_{r<R_1} = \frac{Q_{\text{inside}}}{4\pi \epsilon_0} \frac{1}{r^2} = \frac{kQ_{\text{inside}}}{r^2} = \boxed{0}$$

because $\rho_{r<R_1} = 0$ and, therefore, $Q_{\text{inside}} = 0$.

Evaluate $E_{R_1<r<R_2}$:

$$E_{R_1<r<R_2} = \frac{kQ_{\text{inside}}}{r^2} = \frac{4\pi k\rho}{3r^2}\left(r^3 - R_1^3\right)$$

$$= \boxed{\frac{\rho}{3\epsilon_0 r^2}\left(r^3 - R_1^3\right)}$$

For $r > R_2$:

$$Q_{\text{inside}} = \frac{4\pi\rho}{3}\left(R_2^3 - R_1^3\right)$$

and

$$E_{r>R_2} = \frac{4\pi k\rho}{3r^2}\left(R_2^3 - R_1^3\right)$$

$$= \boxed{\frac{\rho}{3\epsilon_0 r^2}\left(R_2^3 - R_1^3\right)}$$

Remarks: Note that *E* is continuous at *r* = R_2.

Gauss's Law Applications in Cylindrical Symmetry Situations

46 • For your senior project you are in charge of designing a Geiger tube for detecting radiation in the nuclear physics laboratory. This instrument will consist of a long metal cylindrical tube that has a long straight metal wire running down its central axis. The diameter of the wire is to be 0.500 mm and the inside diameter of the tube will be 4.00 cm. The tube is to be filled with a dilute gas in which electrical discharge (breakdown) occurs when the electric field reaches 5.50×10^6 N/C. Determine the maximum linear charge density on the wire if breakdown of the gas is not to happen. Assume that the tube and the wire are infinitely long.

Picture the Problem The electric field of a line charge of infinite length is given by $E_r = \dfrac{1}{2\pi \in_0} \dfrac{\lambda}{r}$, where r is the distance from the center of the line of charge and λ is the linear charge density of the wire.

The electric field of a line charge of infinite length is given by:

$$E_r = \frac{1}{2\pi \in_0} \frac{\lambda}{r}$$

Because E_r varies inversely with r, its maximum value occurs at the surface of the wire where $r = R$, the radius of the wire:

$$E_{\max} = \frac{1}{2\pi \in_0} \frac{\lambda}{R}$$

Solving for λ yields:

$$\lambda = 2\pi \in_0 RE_{\max}$$

Substitute numerical values and evaluate λ:

$$\lambda = 2\pi \left(8.854\times10^{-12}\ \frac{\mathrm{C^2}}{\mathrm{N\cdot m^2}}\right)(0.250\ \mathrm{mm})\left(5.50\times10^{6}\ \frac{\mathrm{N}}{\mathrm{C}}\right) = \boxed{76.5\ \mathrm{nC/m}}$$

47 ••• In Problem 54, suppose ionizing radiation produces an ion and an electron at a distance of 2.00 cm from the long axis of the central wire of the Geiger tube. Suppose that the central wire is positively charged and has a linear charge density equal to 76.5 pC/m. (*a*) In this case, what will be the electron's speed as it impacts the wire? (*b*) Qualitatively, how will the electron's speed compare to that of the ion's final speed when it impacts the outside cylinder? Explain your reasoning.

Picture the Problem Because the inward force on the electron increases as its distance from the wire decreases, we'll need to integrate the net electric force acting on the electron to obtain an expression for its speed as a function of its distance from the wire in the Geiger tube.

(*a*) The force the electron experiences is the radial component of the force on the electron and is the product of its charge and the radial component of the electric field due to the positively charged central wire:

$$F_{e,r} = eE_r$$

The radial electric field due to the charged wire is given by:

$$E_r = \frac{1}{2\pi \in_0} \frac{\lambda}{r}$$

Substituting for E_r yields:

$$F_{e,r}=-\left(\frac{e\lambda}{2\pi\in_0}\right)\frac{1}{r}$$ where the minus sign indicates that the force acting on the electron is radially inward.

Apply Newton's second law to the electron to obtain:

$$-\left(\frac{e\lambda}{2\pi\in_0}\right)\frac{1}{r}=m\frac{dv}{dt}=m\frac{dv}{dt}\frac{dr}{dr}$$
$$=m\frac{dv}{dr}\frac{dr}{dt}=mv\frac{dv}{dr}$$

Separating variables yields:

$$vdv=-\left(\frac{e\lambda}{2\pi m\in_0}\right)\frac{dr}{r}$$

Express the integral of this equation to obtain:

$$\int_0^{v_\mathrm{f}}vdv=-\left(\frac{e\lambda}{2\pi m\in_0}\right)\int_{r_1}^{r_2}\frac{dr}{r}$$ where the lower limit on the left-hand side is zero because the electron is initially at rest.

Integrating yields:

$$\tfrac{1}{2}v_\mathrm{f}^2=-\left(\frac{e\lambda}{2\pi m\in_0}\right)\ln\left(\frac{r_2}{r_1}\right)$$

Solve for v_f to obtain:

$$v_\mathrm{f}=\sqrt{\left(\frac{e\lambda}{\pi m\in_0}\right)\ln\left(\frac{r_1}{r_2}\right)}$$

Substitute numerical values and evaluate v_f:

$$v_\mathrm{f}=\sqrt{\left(\frac{\left(1.602\times10^{-19}\ \mathrm{C}\right)\left(76.5\ \frac{\mathrm{pC}}{\mathrm{m}}\right)}{\pi\left(9.109\times10^{-31}\ \mathrm{kg}\right)\left(8.854\times10^{-12}\ \frac{\mathrm{C}^2}{\mathrm{N\cdot m^2}}\right)}\right)\ln\left(\frac{0.0200\ \mathrm{m}-0.0025\ \mathrm{m}}{0.250\ \mathrm{mm}}\right)}$$
$$=\boxed{1.43\times10^{6}\ \mathrm{m/s}}$$

(*b*) The positive ion is accelerated radially outward and will impact the tube instead of the wire. Because of its much larger mass, the impact speed of the ion will be much less than the impact speed of the electron.

48 •• Show that the electric field due to an infinitely long, uniformly charged thin cylindrical shell of radius a having a surface charge density σ is given by the following expressions: $E = 0$ for $0 \le R < a$ and $E_R = \sigma a/(\epsilon_0 R)$ for $R > a$.

Picture the Problem From symmetry, the field in the tangential direction must vanish. We can construct a Gaussian surface in the shape of a cylinder of radius r and length L and apply Gauss's law to find the electric field as a function of the distance from the centerline of the infinitely long, uniformly charged cylindrical shell.

Apply Gauss's law to the cylindrical surface of radius r and length L that is concentric with the infinitely long, uniformly charged cylindrical shell:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}}$$

or

$$2\pi r L E_R = \frac{Q_{\text{inside}}}{\epsilon_0}$$

where we've neglected the end areas because no there is no flux through them and, due to symmetry, $E_n = E_R$.

Solve for E_R:

$$E_R = \frac{Q_{\text{inside}}}{2\pi r L \epsilon_0} = \frac{2kQ_{\text{inside}}}{Lr}$$

For $R < a$, $Q_{\text{inside}} = 0$ and:

$$E_{R<a} = \boxed{0}$$

For $R > a$, $Q_{\text{inside}} = \lambda L$ and:

$$E_{R>a} = \frac{2k\lambda L}{Lr} = \frac{2k\lambda}{r} = \frac{2k(2\pi a\sigma)}{r} = \boxed{\frac{a\sigma}{\epsilon_0 r}}$$

49 •• A thin cylindrical shell of length 200 m and radius 6.00 cm has a uniform surface charge density of 9.00 nC/m^2. (*a*) What is the total charge on the shell? Find the electric field at the following radial distances from the long axis of the cylinder. (*b*) 2.00 cm, (*c*) 5.90 cm, (*d*) 6.10 cm, and (*e*) 10.0 cm. (Use the results of Problem 48.)

Picture the Problem We can use the definition of surface charge density to find the total charge on the shell. From symmetry, the electric field in the tangential direction must vanish. We can construct a Gaussian surface in the shape of a cylinder of radius r and length L and apply Gauss's law to find the electric field as a function of the distance from the centerline of the uniformly charged cylindrical shell.

(*a*) Using its definition, relate the surface charge density to the total charge on the shell:

$$Q = \sigma A = 2\pi RL\sigma$$

Substitute numerical values and evaluate Q:

$$Q = 2\pi(0.0600\,\text{m})(200\,\text{m})(9.00\,\text{nC/m}^2) = \boxed{679\,\text{nC}}$$

(*b*) From Problem 48 we have, for $r = 2.00$ cm:

$$E_{r=2.00\,\text{cm}} = \boxed{0}$$

(*c*) From Problem 48 we have, for $r = 5.90$ cm:

$$E_{r=5.90\,\text{cm}} = \boxed{0}$$

(*d*) From Problem 48 we have, for $r = 6.10$ cm:

$$E_r = \frac{\sigma R}{\epsilon_0\, r}$$

Substitute numerical values and evaluate $E_{r=6.10\,\text{cm}}$:

$$E_{r=6.10\,\text{cm}} = \frac{(9.00\,\text{nC/m}^2)(0.0600\,\text{m})}{(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)(0.0610\,\text{m})} = \boxed{1.00\,\text{kN/C}}$$

(*e*) From Problem 48 we have, for $r = 10.0$ cm:

$$E_{r=10.0\,\text{cm}} = \frac{(9.00\,\text{nC/m}^2)(0.0600\,\text{m})}{(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)(0.100\,\text{m})} = \boxed{610\,\text{N/C}}$$

50 •• An infinitely long non-conducting solid cylinder of radius a has a uniform volume charge density of ρ_0. Show that the electric field is given by the following expressions: $E_a = \rho_0 a/(2\epsilon_0)$ for $0 \le r < a$ and $E_a = \rho_0 a^2/(2\epsilon_0\, r)$ for $r > a$, where r is the distance from the long axis of the cylinder.

Picture the Problem From symmetry, the field tangent to the surface of the cylinder must vanish. We can construct a Gaussian surface in the shape of a cylinder of radius r and length L and apply Gauss's law to find the electric field as a function of the distance from the centerline of the infinitely long nonconducting cylinder.

Apply Gauss's law to a cylindrical surface of radius r and length L that is concentric with the infinitely long nonconducting cylinder:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}}$$

or

$$2\pi r L E_n = \frac{Q_{\text{inside}}}{\epsilon_0}$$

where we've neglected the end areas because there is no flux through them.

Due to symmetry, $E_n = E_r$. Solving for E_r yields:

$$E_r = \frac{Q_{\text{inside}}}{2\pi r L \epsilon_0} = \frac{2kQ_{\text{inside}}}{Lr}$$

Express Q_{inside} for $r < a$:

$$Q_{\text{inside}} = \rho(r)V = \rho_0(\pi r^2 L)$$

Substitute to obtain:

$$E_{r<R} = \frac{2k(\pi\rho_0 L r^2)}{Lr} = \boxed{\frac{\rho_0}{2\epsilon_0} r}$$

or, because $\lambda = \rho\pi a^2$,

$$E_{r<R} = \boxed{\frac{\lambda}{2\pi\epsilon_0 a^2} r}$$

Express Q_{inside} for $r > a$:

$$Q_{\text{inside}} = \rho(r)V = \rho_0(\pi a^2 L)$$

Substitute for Q_{inside} to obtain:

$$E_{r>a} = \frac{2k(\pi\rho_0 L a^2)}{Lr} = \boxed{\frac{\rho_0 a^2}{2\epsilon_0 r}}$$

or, because $\lambda = \rho\pi a^2$

$$E_{r>a} = \boxed{\frac{\lambda}{2\pi\epsilon_0 r}}$$

51 •• **[SSM]** A solid cylinder of length 200 m and radius 6.00 cm has a uniform volume charge density of 300 nC/m^3. (*a*) What is the total charge of the cylinder? Use the formulas given in Problem 50 to calculate the electric field at a point equidistant from the ends at the following radial distances from the cylindrical axis: (*b*) 2.00 cm, (*c*) 5.90 cm, (*d*) 6.10 cm, and (*e*) 10.0 cm.

Picture the Problem We can use the definition of volume charge density to find the total charge on the cylinder. From symmetry, the electric field tangent to the surface of the cylinder must vanish. We can construct a Gaussian surface in the shape of a cylinder of radius *r* and length *L* and apply Gauss's law to find the electric field as a function of the distance from the centerline of the uniformly charged cylinder.

(*a*) Use the definition of volume charge density to express the total charge of the cylinder:

$$Q_{\text{total}} = \rho V = \rho\left(\pi R^2 L\right)$$

Substitute numerical values to obtain:

$$Q_{\text{total}} = \pi\left(300\,\text{nC/m}^3\right)\left(0.0600\,\text{m}\right)^2\left(200\,\text{m}\right) = \boxed{679\,\text{nC}}$$

(*b*) From Problem 50, for $r < R$, we have:

$$E_{r<R} = \frac{\rho}{2\epsilon_0}r$$

For $r = 2.00$ cm:

$$E_{r=2.00\,\text{cm}} = \frac{\left(300\,\text{nC/m}^3\right)\left(0.0200\,\text{m}\right)}{2\left(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)} = \boxed{339\,\text{N/C}}$$

(*c*) For $r = 5.90$ cm:

$$E_{r=5.90\,\text{cm}} = \frac{\left(300\,\text{nC/m}^3\right)\left(0.0590\,\text{m}\right)}{2\left(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)} = \boxed{1.00\,\text{kN/C}}$$

From Problem 50, for $r > R$, we have:

$$E_{r>R} = \frac{\rho R^2}{2\epsilon_0 r}$$

(*d*) For $r = 6.10$ cm:

$$E_{r=6.10\,\text{cm}} = \frac{\left(300\,\text{nC/m}^3\right)\left(0.0600\,\text{m}\right)^2}{2\left(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(0.0610\,\text{m}\right)} = \boxed{1.00\,\text{kN/C}}$$

(*e*) For $r = 10.0$ cm:

$$E_{r=10.0\,\text{cm}} = \frac{\left(300\,\text{nC/m}^3\right)\left(0.0600\,\text{m}\right)^2}{2\left(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(0.100\,\text{m}\right)} = \boxed{610\,\text{N/C}}$$

52 •• Consider two infinitely long, coaxial thin cylindrical shells. The inner shell has a radius a_1 and has a uniform surface charge density of σ_1, and the outer shell has a radius a_2 and has a uniform surface charge density of σ_2. (*a*) Use Gauss's law to find expressions for the electric field in the three regions: $0 \le r < a_1$, $a_1 < r < a_2$, and $r > a_2$, where *r* is the distance from the axis. (*b*) What is the ratio of the surface charge densities σ_2/σ_1 and their relative signs if the electric field is to be zero everywhere outside the largest cylinder? (*c*) For the case in Part (*b*), what would be the electric field between the shells? (*d*) Sketch the electric field lines for the situation in Part (*b*) if σ_1 is positive.

Picture the Problem From symmetry; the field tangent to the surfaces of the shells must vanish. We can construct a Gaussian surface in the shape of a cylinder of radius *r* and length *L* and apply Gauss's law to find the electric field as a function of the distance from the centerline of the infinitely long, uniformly charged cylindrical shells.

(*a*) Apply Gauss's law to the cylindrical surface of radius *r* and length *L* that is concentric with the infinitely long, uniformly charged cylindrical shell:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 2\pi r L E_n = \frac{Q_{\text{inside}}}{\epsilon_0}$$

where we've neglected the end areas because there is no flux through them.

Noting that, due to symmetry, $E_n = E_r$, Solve for E_r to obtain:

$$E_r = \frac{2kQ_{\text{inside}}}{Lr} \qquad (1)$$

For $r < R_1$, $Q_{\text{inside}} = 0$ and:

$$E_{r<R_1} = \boxed{0}$$

Express Q_{inside} for $a_1 < r < a_2$:

$$Q_{\text{inside}} = \sigma_1 A_1 = 2\pi\sigma_1 a_1 L$$

Substitute in equation (1) to obtain:

$$E_{a_1<r<a_2} = \frac{2k(2\pi\sigma_1 a_1 L)}{Lr} = \boxed{\frac{\sigma_1 a_1}{\epsilon_0 r}}$$

Express Q_{inside} for $r > a_2$:

$$Q_{\text{inside}} = \sigma_1 A_1 + \sigma_2 A_2 = 2\pi\sigma_1 a_1 L + 2\pi\sigma_2 a_2 L$$

Substitute in equation (1) to obtain:

$$E_{r>a_2} = \frac{2k(2\pi\sigma_1 a_1 L + 2\pi\sigma_2 a_2 L)}{Lr} = \boxed{\frac{\sigma_1 a_1 + \sigma_2 a_2}{\epsilon_0 r}}$$

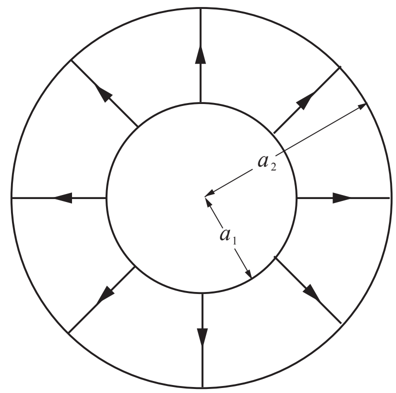
(*b*) Set $E = 0$ for $r > a_2$ to obtain:

$$\frac{\sigma_1 a_1 + \sigma_2 a_2}{\epsilon_0 r} = 0 \Rightarrow \frac{\sigma_2}{\sigma_1} = \boxed{-\frac{a_1}{a_2}}$$

(*c*) Because the electric field is determined by the charge inside the Gaussian surface, the field under these conditions would be as given above:

$$E_{a_1<r<a_2} = \boxed{\frac{\sigma_1 a_1}{\epsilon_0 r}}$$

(*d*) Because σ_1 is positive, the field lines are directed as shown to the right:



53 •• Figure 22-42 shows a portion of an infinitely long, concentric cable in cross section. The inner conductor has a charge of 6.00 nC/m and the outer conductor has no net charge. (*a*) Find the electric field for all values of *R*, where *R* is the perpendicular distance from the common axis of the cylindrical system. (*b*) What are the surface charge densities on the inside and the outside surfaces of the outer conductor?

Picture the Problem The electric field is directed radially outward. We can construct a Gaussian surface in the shape of a cylinder of radius *r* and length *L* and apply Gauss's law to find the electric field as a function of the distance from the centerline of the infinitely long, uniformly charged cylindrical shell.

(*a*) Apply Gauss's law to a cylindrical surface of radius *r* and length *L* that is concentric with the inner conductor:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 2\pi r L E_n = \frac{Q_{\text{inside}}}{\epsilon_0}$$

where we've neglected the end areas because there is no flux through them.

Noting that, due to symmetry, $E_n = E_r$, solve for E_r to obtain:

$$E_r = \frac{2kQ_{\text{inside}}}{Lr} \qquad (1)$$

For $r < 1.50$ cm, $Q_{\text{inside}} = 0$ and:

$$E_{r<1.50\,\text{cm}} = \boxed{0}$$

Letting $R = 1.50$ cm, express Q_{inside} for 1.50 cm < r < 4.50 cm:

$$Q_{\text{inside}} = \lambda L = 2\pi\sigma RL$$

Substitute in equation (1) to obtain:

$$E_{1.50\,\text{cm}<r<4.50\,\text{cm}} = \frac{2k(\lambda L)}{Lr} = \frac{2k\lambda}{r}$$

Substitute numerical values and evaluate $E_{1.50\,\text{cm}<r<4.50\,\text{cm}}$:

$$E_{1.50\,\text{cm}<r<4.50\,\text{cm}} = 2\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(6.00\,\text{nC/m})}{r} = \boxed{\frac{(108\,\text{N}\cdot\text{m/C})}{r}}$$

Express Q_{inside} for 4.50 cm < r < 6.50 cm:

$$Q_{\text{inside}} = 0$$

and

$$E_{4.50\,\text{cm}<r<6.50\,\text{cm}} = \boxed{0}$$

Because the net charge on the outer conductor is zero:

$$Q_{\text{inside}} = \lambda L$$

Substitute in equation (1) to obtain:

$$E_r = \frac{2k\lambda L}{Lr} = \frac{\lambda}{2\pi \in_0 r}$$

Substitute numerical values and evaluate $E_{r>6.50\,\text{cm}}$:

$$E_{r>6.50\,\text{cm}} = \frac{6.00\times10^{-9}\ \text{C/m}}{2\pi\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)r} = \boxed{\frac{108\,\text{N}\cdot\text{m/C}}{r}}$$

(*b*) The surface charge densities on the inside and the outside surfaces of the outer conductor are given by:

$$\sigma_{\text{inside}} = \frac{-\lambda}{2\pi R_{\text{inside}}}$$

and

$$\sigma_{\text{outside}} = \frac{\lambda}{2\pi R_{\text{outside}}}$$

Substitute numerical values and evaluate σ_{inside} and σ_{outside}:

$$\sigma_{\text{inside}} = \frac{-6.00\,\text{nC/m}}{2\pi(0.0450\,\text{m})} = -21.22\,\text{nC/m}^2 = \boxed{-21.2\,\text{nC/m}^2}$$

and

$$\sigma_{\text{outside}} = \frac{6.00\,\text{nC/m}}{2\pi(0.0650\,\text{m})} = \boxed{14.7\,\text{nC/m}^2}$$

54 •• An infinitely long non-conducting solid cylinder of radius a has a non-uniform volume charge density. This density varies linearly with R, the perpendicular distance from its axis, according to $\rho(R) = \beta R$, where β is a constant. (a) Show that the linear charge density of the cylinder is given by $\lambda = 2\pi\beta a^3/3$. ($b$) Find expressions for the electric field for $R < a$ and $R > a$.

Picture the Problem From symmetry considerations, we can conclude that the field tangent to the surface of the cylinder must vanish. We can construct a Gaussian surface in the shape of a cylinder of radius r and length L and apply Gauss's law to find the electric field as a function of the distance from the centerline of the infinitely long nonconducting cylinder.

(a) The linear charge density of the cylinder is given by:

$$\lambda = \frac{q}{L} \qquad (1)$$

The total charge q in the long non-conducting solid cylinder is given by:

$$q = \int \rho(R)dV$$

Substituting for $\rho(R)$ and dV gives:

$$q = \int \beta R(2\pi RLdR)$$

Substitute for q in equation (1) and simplify to obtain:

$$\lambda = 2\pi\beta\int_0^a R^2 dR = \boxed{\frac{2\pi\beta a^3}{3}}$$

(b) Apply Gauss's law to a cylindrical surface of radius R and length L that is concentric with the infinitely long nonconducting cylinder:

$$\oint_S E_n dA = \frac{1}{\epsilon_0}Q_{\text{inside}} \Rightarrow 2\pi RLE_n = \frac{Q_{\text{inside}}}{\epsilon_0}$$

where we've neglected the end areas because there is no flux through them.

Noting that, due to symmetry, $E_n = E_R$, solve for E_R to obtain:

$$E_R = \frac{Q_{\text{inside}}}{2\pi RL\epsilon_0} \qquad (2)$$

Express dQ_{inside} for $\rho(R) = \beta R$:

$$dQ_{\text{inside}} = \rho(R)dV = \beta R(2\pi RL)dR = 2\pi\beta R^2 LdR$$

Integrate dQ_{inside} from $R = 0$ to r to obtain:

$$Q_{\text{inside}} = 2\pi\beta L\int_0^r R^2 dR = 2\pi aL\left[\frac{R^3}{3}\right]_0^r = \frac{2\pi\beta Lr^3}{3}$$

Substitute for Q_{inside} in equation (2) and simplify to obtain:

$$E_{R<a} = \frac{\frac{2\pi\beta Lr^3}{3}}{2\pi \in_0 Lr} = \boxed{\frac{\beta}{3\in_0}r^2}$$

For $R > a$:

$$Q_{\text{inside}} = \lambda L = \frac{2\pi\beta La^3}{3}$$

Substitute for Q_{inside} in equation (1) and simplify to obtain:

$$E_{R>a} = \frac{\frac{2\pi\beta La^3}{3}}{2\pi rL\in_0} = \boxed{\frac{\beta}{3r\in_0}a^3}$$

55 •• [SSM] An infinitely long non-conducting solid cylinder of radius a has a non-uniform volume charge density. This density varies with R, the perpendicular distance from its axis, according to $\rho(R) = bR^2$, where b is a constant. (a) Show that the linear charge density of the cylinder is given by $\lambda = \pi ba^4/2$. (b) Find expressions for the electric field for $R < a$ and $R > a$.

Picture the Problem From symmetry; the field tangent to the surface of the cylinder must vanish. We can construct a Gaussian surface in the shape of a cylinder of radius r and length L and apply Gauss's law to find the electric field as a function of the distance from the centerline of the infinitely long nonconducting cylinder.

(a) Apply Gauss's law to a cylindrical surface of radius R and length L that is concentric with the infinitely long nonconducting cylinder:

$$\oint_S E_n dA = \frac{1}{\in_0}Q_{\text{inside}} \Rightarrow 2\pi RLE_n = \frac{Q_{\text{inside}}}{\in_0}$$

where we've neglected the end areas because there is no flux through them.

Noting that, due to symmetry, $E_n = E_R$, solve for E_R to obtain:

$$E_R = \frac{Q_{\text{inside}}}{2\pi RL\in_0} \qquad (1)$$

Express dQ_{inside} for $\rho(R) = bR^2$:

$$dQ_{\text{inside}} = \rho(R)dV = bR^2(2\pi RL)dR = 2\pi bR^3 LdR$$

Integrate dQ_{inside} from 0 to R to obtain:

$$Q_{\text{inside}} = 2\pi bL\int_0^R R^3 dr = 2\pi bL\left[\frac{R^4}{4}\right]_0^R = \frac{\pi bL}{2}R^4$$

Divide both sides of this equation by L to obtain an expression for the charge per unit length λ of the cylinder:

$$\lambda = \frac{Q_{\text{inside}}}{L} = \boxed{\frac{\pi bR^4}{2}}$$

(b) Substitute for Q_{inside} in equation (1) and simplify to obtain:

$$E_{R<a} = \frac{\frac{\pi bL}{2}r^4}{2\pi Lr\in_0} = \boxed{\frac{b}{4\in_0}r^3}$$

For $r > a$:

$$Q_{\text{inside}} = \frac{\pi bL}{2}a^4$$

Substitute for Q_{inside} in equation (1) and simplify to obtain:

$$E_{R>a} = \frac{\frac{\pi bL}{2}a^4}{2\pi rL\in_0} = \boxed{\frac{ba^4}{4\in_0 r}}$$

56 ••• An infinitely long, non-conducting cylindrical shell of inner radius a_1 and outer radius a_2 has a uniform volume charge density ρ. Find expressions for the electric field everywhere.

Picture the Problem From symmetry; the field tangent to the surface of the cylinder must vanish. We can construct a Gaussian surface in the shape of a cylinder of radius r and length L and apply Gauss's law to find the electric field as a function of the distance from the centerline of the infinitely long nonconducting cylindrical shell.

Apply Gauss's law to a cylindrical surface of radius r and length L that is concentric with the infinitely long nonconducting cylindrical shell:

$$\oint_S E_n dA = \frac{1}{\in_0}Q_{\text{inside}} \Rightarrow 2\pi rLE_n = \frac{Q_{\text{inside}}}{\in_0}$$

where we've neglected the end areas because no flux crosses them.

Noting that, due to symmetry, $E_n = E_r$, solve for E_r to obtain:

$$E_r = \frac{Q_{\text{inside}}}{2\pi rL \in_0}$$

For $r < a_1$, $Q_{\text{inside}} = 0$:

$$E_{r<a_1} = \boxed{0}$$

Express Q_{inside} for $a_1 < r < a_2$:

$$Q_{\text{inside}} = \rho V = \rho\pi r^2 L - \rho\pi a_1^2 L = \rho\pi L\left(r^2 - a_1^2\right)$$

Substitute for Q_{inside} and simplify to obtain:

$$E_{a_1<r<a_2} = \frac{\rho\pi L\left(r^2 - a_1^2\right)}{2\pi \in_0 Lr} = \boxed{\frac{\rho\left(r^2 - a_1^2\right)}{2 \in_0 r}}$$

Express Q_{inside} for $r > a_2$:

$$Q_{\text{inside}} = \rho V = \rho\pi a_2^2 L - \rho\pi a_1^2 L = \rho\pi L\left(a_2^2 - a_1^2\right)$$

Substitute for Q_{inside} and simplify to obtain:

$$E_{r>a_2} = \frac{\rho\pi L\left(a_2^2 - a_1^2\right)}{2\pi \in_0 rL} = \boxed{\frac{\rho\left(a_2^2 - a_1^2\right)}{2 \in_0 r}}$$

57 ••• [SSM] The inner cylinder of Figure 22-42 is made of non-conducting material and has a volume charge distribution given by $\rho(R) = C/R$, where $C = 200$ nC/m^2. The outer cylinder is metallic, and both cylinders are infinitely long. (*a*) Find the charge per unit length (that is, the linear charge density) on the inner cylinder. (*b*) Calculate the electric field for all values of R.

Picture the Problem We can integrate the density function over the radius of the inner cylinder to find the charge on it and then calculate the linear charge density from its definition. To find the electric field for all values of r we can construct a Gaussian surface in the shape of a cylinder of radius r and length L and apply Gauss's law to each region of the cable to find the electric field as a function of the distance from its centerline.

(*a*) Find the charge Q_{inner} on the inner cylinder:

$$Q_{\text{inner}} = \int_0^R \rho(r)dV = \int_0^R \frac{C}{r} 2\pi rLdr = 2\pi CL\int_0^R dr = 2\pi CLR$$

Relate this charge to the linear charge density:

$$\lambda = \frac{Q_{\text{inner}}}{L} = \frac{2\pi CLR}{L} = 2\pi CR$$

Substitute numerical values and evaluate λ:

$$\lambda = 2\pi(200\,\text{nC/m})(0.0150\,\text{m}) = \boxed{18.8\,\text{nC/m}}$$

(*b*) Apply Gauss's law to a cylindrical surface of radius *r* and length *L* that is concentric with the infinitely long nonconducting cylinder:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 2\pi r L E_n = \frac{Q_{\text{inside}}}{\epsilon_0}$$

where we've neglected the end areas because there is no flux through them.

Noting that, due to symmetry, $E_n = E_r$, solve for E_r to obtain:

$$E_r = \frac{Q_{\text{inside}}}{2\pi r L \epsilon_0}$$

Substitute to obtain, for $r < 1.50$ cm:

$$E_{r<1.50\,\text{cm}} = \frac{2\pi C L r}{2\pi \epsilon_0 L r} = \frac{C}{\epsilon_0}$$

Substitute numerical values and evaluate $E_\text{n}(r < 1.50\text{ cm})$:

$$E_{r<1.50\,\text{cm}} = \frac{200\,\text{nC/m}^2}{8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2} = \boxed{22.6\,\text{kN/C}}$$

Express Q_{inside} for 1.50 cm $< r <$ 4.50 cm:

$$Q_{\text{inside}} = 2\pi C L R$$

Substitute to obtain, for 1.50 cm $< r <$ 4.50 cm:

$$E_{1.50\,\text{cm}<r<4.50\,\text{cm}} = \frac{2C\pi R L}{2\pi \epsilon_0 r L} = \frac{CR}{\epsilon_0 r}$$

where $R = 1.50$ cm.

Substitute numerical values and evaluate $E_{1.50\,\text{cm}<r<4.50\,\text{cm}}$:

$$E_{1.50\,\text{cm}<r<4.50\,\text{cm}} = \frac{(200\,\text{nC/m}^2)(0.0150\,\text{m})}{(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)r} = \boxed{\frac{339\,\text{N}\cdot\text{m/C}}{r}}$$

Because the outer cylindrical shell is a conductor:

$$E_{4.50\,\text{cm}<r<6.50\,\text{cm}} = \boxed{0}$$

For $r > 6.50$ cm, $Q_{\text{inside}} = 2\pi C L R$ and:

$$E_{r>6.50\,\text{cm}} = \boxed{\frac{339\,\text{N}\cdot\text{m/C}}{r}}$$

Electric Charge and Field at Conductor Surfaces

58 • An uncharged penny is in a region that has a uniform electric field of magnitude 1.60 kN/C directed perpendicular to its faces. (*a*) Find the charge density on each face of the penny, assuming the faces are planes. (*b*) If the radius of the penny is 1.00 cm, find the total charge on one face.

Picture the Problem Because the penny is in an external electric field, it will have charges of opposite signs induced on its faces. The induced charge σ is related to the electric field by $E = \sigma/\epsilon_0$. Once we know σ, we can use the definition of surface charge density to find the total charge on one face of the penny.

(*a*) Relate the electric field to the charge density on each face of the penny:

$$E = \frac{\sigma}{\epsilon_0} \Rightarrow \sigma = \epsilon_0 E$$

Substitute numerical values and evaluate σ:

$$\sigma = \left(8.854\times10^{-12}\,\mathrm{C^2/N\cdot m^2}\right)\left(1.60\,\mathrm{kN/C}\right) = 14.17\,\mathrm{nC/m^2} = \boxed{14.2\,\mathrm{nC/m^2}}$$

(*b*) Use the definition of surface charge density to obtain:

$$\sigma = \frac{Q}{A} = \frac{Q}{\pi r^2} \Rightarrow Q = \sigma\pi r^2$$

Substitute numerical values and evaluate Q:

$$Q = \pi\left(14.17\,\mathrm{nC/m^2}\right)\left(0.0100\,\mathrm{m}\right)^2 = \boxed{4.45\,\mathrm{pC}}$$

59 • A thin metal slab has a net charge of zero and has square faces that have 12-cm-long sides. It is in a region that has a uniform electric field that is perpendicular to its faces. The total charge induced on one of the faces is 1.2 nC. What is the magnitude of the electric field?

Picture the Problem Because the metal slab is in an external electric field, it will have charges of opposite signs induced on its faces. The induced charge σ is related to the electric field by $E = \sigma/\epsilon_0$.

Relate the magnitude of the electric field to the charge density on the metal slab:

$$E = \frac{\sigma}{\epsilon_0}$$

Use its definition to express σ:

$$\sigma = \frac{Q}{A} = \frac{Q}{L^2}$$

Substitute for σ to obtain:

$$E = \frac{Q}{L^2 \in_0}$$

Substitute numerical values and evaluate E:

$$E = \frac{1.2\,\text{nC}}{(0.12\,\text{m})^2\left(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)} = \boxed{9.4\,\text{kN/C}}$$

60 •• A charge of -6.00 nC is uniformly distributed on a thin square sheet of non-conducting material of edge length 20.0 cm. (*a*) What is the surface charge density of the sheet? (*b*) What are the magnitude and direction of the electric field next to the sheet and proximate to the center of the sheet?

Picture the Problem We can apply its definition to find the surface charge density of the nonconducting material and calculate the electric field at either of its surfaces from $\sigma/(2\in_0)$.

(*a*) Use its definition to find σ:

$$\sigma = \frac{Q}{A} = \frac{-6.00\,\text{nC}}{(0.200\,\text{m})^2} = \boxed{-150\,\text{nC/m}^2}$$

(*b*) The magnitude of the electric field just outside the surface of the sheet on the side that is charged is given by:

$$|E| = \frac{\sigma}{2\in_0} = \left|\frac{-150\,\text{nC/m}^2}{2\left(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}\right| = \boxed{8.47\,\text{kN/C}}$$

The direction of the field on the side of the sheet that is charged is the direction of the electric force acting on a test charge. Because the surface is negatively charged, this force and, hence, the electric field, is directed toward the surface.

Because the sheet is constructed from non-conducting material, no charge is induced on the second surface of the sheet and there is, therefore, no electric field just outside the sheet surface on this side.

61 • A conducting spherical shell that has zero net charge has an inner radius R_1 and an outer radius R_2. A positive point charge q is placed at the center of the shell. (*a*) Use Gauss's law and the properties of conductors in electrostatic equilibrium to find the electric field in the three regions: $0 \le r < R_1$, $R_1 < r < R_2$, and $r > R_2$, where r is the distance from the center. (*b*) Draw the electric field lines in all three regions. (*c*) Find the charge density on the inner surface ($r = R_1$) and on the outer surface ($r = R_2$) of the shell.

Picture the Problem We can construct a Gaussian surface in the shape of a sphere of radius r with the same center as the shell and apply Gauss's law to find

the electric field as a function of the distance from this point. The inner and outer surfaces of the shell will have charges induced on them by the charge q at the center of the shell.

(*a*) Apply Gauss's law to a spherical surface of radius r that is concentric with the point charge:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 4\pi r^2 E_n = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Noting that, due to symmetry, $E_n = E_r$, solve for E_r to obtain:

$$E_r = \frac{Q_{\text{inside}}}{4\pi r^2 \epsilon_0} \quad (1)$$

For $r < R_1$, $Q_{\text{inside}} = q$. Substitute in equation (1) and simplify to obtain:

$$E_{r<R_1} = \frac{q}{4\pi r^2 \epsilon_0} = \boxed{\frac{kq}{r^2}}$$

Because the spherical shell is a conductor, a charge $-q$ will be induced on its inner surface. Hence, for $R_1 < r < R_2$:

$$Q_{\text{inside}} = 0$$

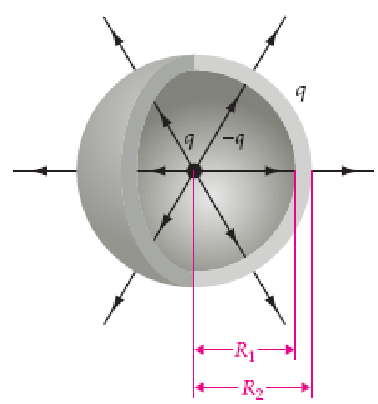
and

$$E_{R_1<r<R_2} = \boxed{0}$$

For $r > R_2$, $Q_{\text{inside}} = q$. Substitute in equation (1) and simplify to obtain:

$$E_{r>R_2} = \frac{q}{4\pi r^2 \epsilon_0} = \boxed{\frac{kq}{r^2}}$$

(*b*) The electric field lines are shown in the diagram to the right:



(*c*) A charge $-q$ is induced on the inner surface. Use the definition of surface charge density to obtain:

$$\sigma_{\text{inner}} = \boxed{-\frac{q}{4\pi R_1^2}}$$

A charge q is induced on the outer surface. Use the definition of surface charge density to obtain:

$$\sigma_{\text{outer}} = \boxed{\frac{q}{4\pi R_2^2}}$$

62 •• The electric field just above the surface of Earth has been measured to typically be 150 N/C pointing downward. (*a*) What is the sign of the net charge on Earth's surface under typical conditions? (*b*)What is the total charge on Earth's surface implied by this measurement?

Picture the Problem We can construct a spherical Gaussian surface at the surface of Earth (we'll assume Earth is a sphere) and apply Gauss's law to relate the electric field to its total charge.

(*a*) Because the direction of an electric field is the direction of the force acting on a positively charged object, the net charge on Earth's surface must be negative.

(*b*)Apply Gauss's law to a spherical surface of radius R_E that is concentric with Earth:

$$\oint_S E_n dA = \frac{1}{\epsilon_0}Q_{\text{inside}} \Rightarrow 4\pi R_E^2 E_E = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Solve for $Q_{\text{inside}} = Q_{\text{Earth}}$ to obtain:

$$Q_{\text{Earth}} = 4\pi \epsilon_0 R_E^2 E_E = \frac{R_E^2 E_E}{k}$$

Substitute numerical values and evaluate Q_{Earth}:

$$Q_{\text{Earth}} = \frac{(6.37\times10^6\ \text{m})^2(150\ \text{N/C})}{8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = \boxed{677\ \text{kC}}$$

63 •• **[SSM]** A positive point charge of 2.5 μC is at the center of a conducting spherical shell that has a net charge of zero, an inner radius equal to 60 cm, and an outer radius equal to 90 cm. (*a*) Find the charge densities on the inner and outer surfaces of the shell and the total charge on each surface. (*b*) Find the electric field everywhere. (*c*) Repeat Part (*a*) and Part (*b*) with a net charge of +3.5 μC placed on the shell.

Picture the Problem Let the inner and outer radii of the uncharged spherical conducting shell be R_1 and R_2 and q represent the positive point charge at the center of the shell. The positive point charge at the center will induce a negative charge on the inner surface of the shell and, because the shell is uncharged, an equal positive charge will be induced on its outer surface. To solve Part (*b*), we can construct a Gaussian surface in the shape of a sphere of radius r with the same center as the shell and apply Gauss's law to find the electric field as a function of the distance from this point. In Part (*c*) we can use a similar strategy with the additional charge placed on the shell.

(a) Express the charge density on the inner surface:

$$\sigma_{\text{inner}} = \frac{q_{\text{inner}}}{A}$$

Express the relationship between the positive point charge q and the charge induced on the inner surface q_{inner}:

$$q + q_{\text{inner}} = 0 \Rightarrow q_{\text{inner}} = -q$$

Substitute for q_{inner} and A to obtain:

$$\sigma_{\text{inner}} = \frac{-q}{4\pi R_1^2}$$

Substitute numerical values and evaluate σ_{inner}:

$$\sigma_{\text{inner}} = \frac{-2.5\,\mu\text{C}}{4\pi(0.60\,\text{m})^2} = \boxed{-0.55\,\mu\text{C/m}^2}$$

Express the charge density on the outer surface:

$$\sigma_{\text{outer}} = \frac{q_{\text{outer}}}{A}$$

Because the spherical shell is uncharged:

$$q_{\text{outer}} + q_{\text{inner}} = 0$$

Substitute for q_{outer} to obtain:

$$\sigma_{\text{outer}} = \frac{-q_{\text{inner}}}{4\pi R_2^2}$$

Substitute numerical values and evaluate σ_{outer}:

$$\sigma_{\text{outer}} = \frac{2.5\,\mu\text{C}}{4\pi(0.90\,\text{m})^2} = \boxed{0.25\,\mu\text{C/m}^2}$$

(b) Apply Gauss's law to a spherical surface of radius r that is concentric with the point charge:

$$\oint_S E_n dA = \frac{1}{\epsilon_0} Q_{\text{inside}} \Rightarrow 4\pi r^2 E_n = \frac{Q_{\text{inside}}}{\epsilon_0}$$

Noting that, due to symmetry, $E_n = E_r$, solve for E_r to obtain:

$$E_r = \frac{Q_{\text{inside}}}{4\pi r^2 \epsilon_0} \qquad (1)$$

For $r < R_1 = 60$ cm, $Q_{\text{inside}} = q$. Substitute in equation (1) to obtain:

$$E_{r<60\,\text{cm}} = \frac{q}{4\pi r^2 \epsilon_0} = \frac{kq}{r^2}$$

Substitute numerical values and evaluate $E_{r<60\,\text{cm}}$:

$$E_{r<60\,\text{cm}} = \frac{\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(2.5\ \mu\text{C}\right)}{r^2} = \boxed{\left(2.2\times10^{4}\ \text{N}\cdot\text{m}^2/\text{C}\right)\frac{1}{r^2}}$$

Because the spherical shell is a conductor, a charge $-q$ will be induced on its inner surface. Hence, for 60 cm < r < 90 cm:

$Q_{\text{inside}} = 0$

and

$E_{60\,\text{cm}<r<90\,\text{cm}} = \boxed{0}$

For r > 90 cm, the net charge inside the Gaussian surface is q and:

$$E_{r>90\,\text{cm}} = \frac{kq}{r^2} = \boxed{\left(2.3\times10^{4}\ \text{N}\cdot\text{m}^2/\text{C}\right)\frac{1}{r^2}}$$

(*c*) Because E = 0 in the conductor:

$q_{\text{inner}} = -2.5\ \mu\text{C}$

and

$\sigma_{\text{inner}} = \boxed{-0.55\ \mu\text{C/m}^2}$ as before.

Express the relationship between the charges on the inner and outer surfaces of the spherical shell:

$q_{\text{outer}} + q_{\text{inner}} = 3.5\ \mu\text{C}$

and

$q_{\text{outer}} = 3.5\ \mu\text{C} - q_{\text{inner}} = 6.0\ \mu\text{C}$

σ_{outer} is now given by:

$$\sigma_{\text{outer}} = \frac{6.0\ \mu\text{C}}{4\pi\left(0.90\ \text{m}\right)^2} = \boxed{0.59\ \mu\text{C/m}^2}$$

For $r < R_1$ = 60 cm, $Q_{\text{inside}} = q$ and $E_{r<60\,\text{cm}}$ is as it was in (*a*):

$$E_{r<60\,\text{cm}} = \boxed{\left(2.3\times10^{4}\ \text{N}\cdot\text{m}^2/\text{C}\right)\frac{1}{r^2}}$$

Because the spherical shell is a conductor, a charge $-q$ will be induced on its inner surface. Hence, for 60 cm < r < 90 cm:

$Q_{\text{inside}} = 0$

and

$E_{60\,\text{cm}<r<90\,\text{cm}} = \boxed{0}$

For r > 0.90 m, the net charge inside the Gaussian surface is 6.0 μC and:

$$E_{r>90\,\text{cm}} = \frac{kq}{r^2} = \left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(6.0\ \mu\text{C}\right)\frac{1}{r^2} = \boxed{\left(5.4\times10^{4}\ \text{N}\cdot\text{m}^2/\text{C}\right)\frac{1}{r^2}}$$

64 •• If the magnitude of an electric field in air is as great as 3.0×10^6 N/C, the air becomes ionized and begins to conduct electricity. This phenomenon is called *dielectric breakdown*. A charge of 18 μC is to be placed on a conducting sphere. What is the minimum radius of a sphere that can hold this charge without breakdown?

Picture the Problem From Gauss's law we know that the electric field at the surface of the charged sphere is given by $E = kQ/R^2$ where Q is the charge on the sphere and R is its radius. The minimum radius for dielectric breakdown corresponds to the maximum electric field at the surface of the sphere.

Use Gauss's law to express the electric field at the surface of the charged sphere:

$$E = \frac{kQ}{R^2}$$

Express the relationship between E and R for dielectric breakdown:

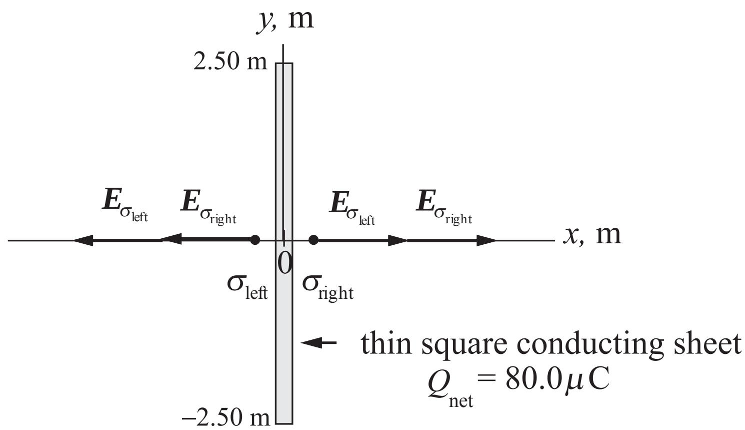
$$E_{\text{max}} = \frac{kQ}{R_{\text{min}}^2} \Rightarrow R_{\text{min}} = \sqrt{\frac{kQ}{E_{\text{max}}}}$$

Substitute numerical values and evaluate R_{min}:

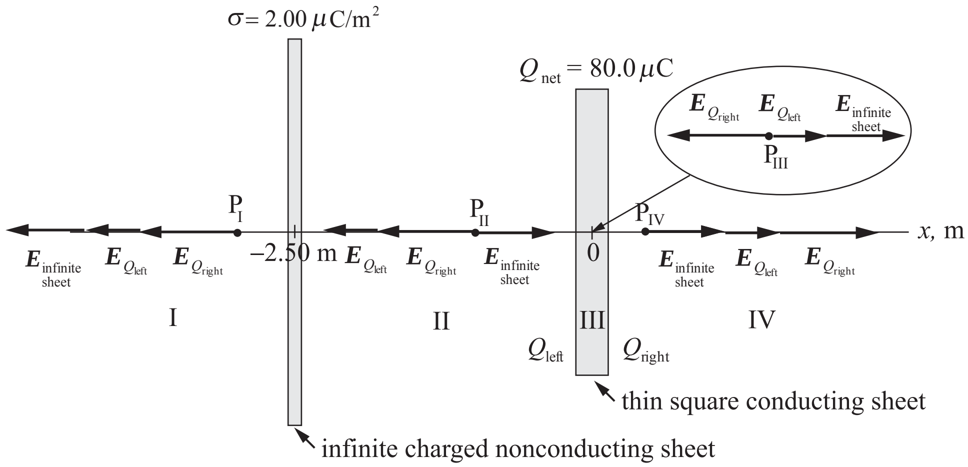
$$R_{\text{min}} = \sqrt{\frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(18\ \mu\text{C}\right)}{3.0\times10^6\ \text{N/C}}} = \boxed{23\,\text{cm}}$$

65 ••• **[SSM]** A thin square conducting sheet that has 5.00-m-long edges has a net charge of 80.0 μC. The square is in the $x = 0$ plane and is centered at the origin.(Assume the charge on each surface is uniformly distributed.) (*a*) Find the charge density on each side of the sheet and find the electric field on the x axis in the region $|x| << 5.00$ m. (*b*) A thin but infinite nonconducting sheet that has a uniform charge density of 2.00 $\mu\text{C/m}^2$ is now placed in the $x = -2.50$ m plane. Find the electric field on the x axis on each side of the square sheet in the region $|x| << 2.50$ m. Find the charge density on each surface of the square sheet.

Picture the Problem (*a*) One half of the total charge is on each side of the conducting sheet and the electric field inside the conducting sheet is zero. The electric field intensity just outside the surface of a conductor is given by $E = |\sigma|/\epsilon_0$. Typical field points to the left and right of the conducting sheet are shown in the following diagram.



(*b*) We can use the fact that the net charge on the conducting sheet is the sum of the charges Q_{left} and Q_{right} on its left and right surfaces to obtain an equation relating these charges. Because the resultant electric field is zero inside the sheet, we can obtain a second equation in Q_{left} and Q_{right} that we can solve simultaneously with the first equation to find Q_{left} and Q_{right}. The resultant electric field is the superposition of three fields–the field due to the charges on the infinite nonconducting sheet and the fields due to the charges on the surfaces of the thin square conducting sheet. The electric field intensity due to a uniformly charged nonconducting infinite sheet is given by $E = |\sigma|/2\in_0$. Typical field points for each of the four regions of interest are shown in the following diagram.



Note: The vectors in this figure are drawn consistent with the charges Q_{left} and Q_{right} both being positive. If either Q_{left} or Q_{right} are negative then the solution will produce a negative value for either Q_{left} or Q_{right}.

(*a*) Because the square sheet is a conductor, half the charge on each surface is half the net charge on the sheet:

$$\sigma_{\text{left}} = \sigma_{\text{right}} = \frac{\frac{1}{2}Q_{\text{net}}}{A}$$

Substitute numerical values and evaluate σ_{left} and σ_{right}:

$$\sigma_{\text{left}} = \sigma_{\text{right}} = \frac{\frac{1}{2}(80.0\ \mu\text{C})}{(5.00\ \text{m})^2} = \boxed{1.60\ \frac{\mu\text{C}}{\text{m}^2}}$$

For $|x| << 5.00$ m, the electric field is given by the expression for the field just outside a conductor:

$$E_{|x|<<5.00\ \text{m}} = \frac{\sigma}{\epsilon_0}$$

Substitute numerical values and evaluate $E_{|x|<<5.00\ \text{m}}$:

$$E_{|x|<<5.00\ \text{m}} = \frac{1.60\ \mu\text{C/m}^2}{8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = 180.7\ \text{kN/C} = \boxed{181\ \text{kN/C}}$$

For $x > 0$, $E_{|x|<<5.00\ \text{m}}$ is in the $+x$ direction and for $x < 0$, $E_{|x|<<5.00\ \text{m}}$ is in the $-x$ direction.

(*b*) The resultant electric field in Region II is the sum of the fields due to the infinite nonconducting sheet and the charge on the surfaces of the thin square conducting sheet:

$$\vec{E}_{\text{II}} = \vec{E}_{\substack{\text{infinite}\\ \text{sheet}}} + \vec{E}_{Q_{\text{left}}} + \vec{E}_{Q_{\text{right}}} = \frac{\sigma_{\substack{\text{infinite}\\ \text{sheet}}}}{2\epsilon_0}\hat{i} - \frac{\sigma_{\text{left}}}{2\epsilon_0}\hat{i} - \frac{\sigma_{\text{right}}}{2\epsilon_0}\hat{i} = \left(\frac{\sigma_{\substack{\text{infinite}\\ \text{sheet}}} - \sigma_{\text{left}} - \sigma_{\text{right}}}{2\epsilon_0}\right)\hat{i}$$

Due to the presence of the infinite nonconducting sheet, the charges on the thin square conducting sheet are redistributed on the left and right surfaces. The net charge on the thin square conducting sheet is the sum of the charges on its left- and right-hand surfaces:

$$Q_{\text{left}} + Q_{\text{right}} = 80.0\ \mu\text{C}$$

where we've assumed that Q_{left} and Q_{right} are both positive.

Writing this equation in terms of the surface charge densities yields:

$$\sigma_{\text{left}}+\sigma_{\text{right}}=\frac{Q_{\text{left}}}{A}+\frac{Q_{\text{right}}}{A}=\frac{Q_{\text{left}}+Q_{\text{right}}}{A}=\frac{80.0\ \mu\text{C}}{(5.00\ \text{m})^2}=3.20\ \mu\text{C/m}^2 \qquad (1)$$

where A is the area of one side of the thin square conducting sheet.

Because the electric field is zero inside the thin square conducting sheet:

$$\frac{\sigma_{\substack{\text{infinite}\\ \text{sheet}}}}{2\epsilon_0}+\frac{\sigma_{\text{left}}}{2\epsilon_0}-\frac{\sigma_{\text{right}}}{2\epsilon_0}=0$$

or

$$2.00\ \mu\text{C/m}^2+\sigma_{\text{left}}-\sigma_{\text{right}}=0 \qquad (2)$$

Solving equations (1) and (2) simultaneously yields:

$$\sigma_{\text{left}}=\boxed{0.60\ \mu\text{C/m}^2}$$

and

$$\sigma_{\text{right}}=\boxed{2.60\ \mu\text{C/m}^2}$$

Substitute numerical values and evaluate $\vec{E}_{\text{II}}$:

$$\vec{E}_{\text{II}}=\left(\frac{2.00\frac{\mu\text{C}}{\text{m}^2}-0.60\frac{\mu\text{C}}{\text{m}^2}-2.60\frac{\mu\text{C}}{\text{m}^2}}{2\left(8.854\times10^{-12}\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)}\right)\hat{\boldsymbol{i}}=\boxed{\left(-67.8\frac{\text{kN}}{\text{C}}\right)\hat{\boldsymbol{i}}}$$

The resultant electric field in Region IV is the sum of the fields due to the charge on the infinite nonconducting sheet and the charges on the two surfaces of the thin square conducting sheet:

$$\vec{E}_{\text{IV}}=\vec{E}_{\substack{\text{infinite}\\ \text{sheet}}}+\vec{E}_{Q_{\text{left}}}+\vec{E}_{Q_{\text{right}}}=\frac{\sigma_{\substack{\text{infinite}\\ \text{sheet}}}}{2\epsilon_0}\hat{\boldsymbol{i}}+\frac{\sigma_{\text{left}}}{2\epsilon_0}\hat{\boldsymbol{i}}+\frac{\sigma_{\text{right}}}{2\epsilon_0}\hat{\boldsymbol{i}}=\left(\frac{\sigma_{\substack{\text{infinite}\\ \text{sheet}}}+\sigma_{\text{left}}+\sigma_{\text{right}}}{2\epsilon_0}\right)\hat{\boldsymbol{i}}$$

Substitute numerical values and evaluate $\vec{E}_{IV}$:

$$\vec{E}_{IV} = \left(\frac{2.00\frac{\mu C}{m^2} + 0.60\frac{\mu C}{m^2} + 2.60\frac{\mu C}{m^2}}{2\left(8.854\times10^{-12}\frac{C^2}{N\cdot m^2}\right)} \right)\hat{i} = \boxed{\left(294\frac{kN}{C}\right)\hat{i}}$$

General Problems

66 •• Consider the concentric metal sphere and spherical shells that are shown in Figure 22-43. The innermost is a solid sphere that has a radius R_1. A spherical shell surrounds the sphere and has an inner radius R_2 and an outer radius R_3. The sphere and the shell are both surrounded by a second spherical shell that has an inner radius R_4 and an outer radius R_5. None of these three objects initially have a net charge. Then, a negative charge $-Q_0$ is placed on the inner sphere and a positive charge $+Q_0$ is placed on the outermost shell. (*a*) After the charges have reached equilibrium, what will be the direction of the electric field between the inner sphere and the middle shell? (*b*) What will be the charge on the inner surface of the middle shell? (*c*) What will be the charge on the outer surface of the middle shell? (*d*) What will be the charge on the inner surface of the outermost shell? (*e*) What will be the charge on the outer surface of the outermost shell? (*f*) Plot E as a function of r for all values of r.

Determine the Concept We can determine the direction of the electric field between spheres I and II by imagining a test charge placed between the spheres and determining the direction of the force acting on it. We can determine the amount and sign of the charge on each sphere by realizing that the charge on a given surface induces a charge of the same magnitude but opposite sign on the next surface of larger radius.

(*a*) The charge placed on sphere III has no bearing on the electric field between spheres I and II. The field in this region will be in the direction of the force exerted on a test charge placed between the spheres. Because the charge at the center is negative, $\boxed{\text{the field will point toward the center.}}$

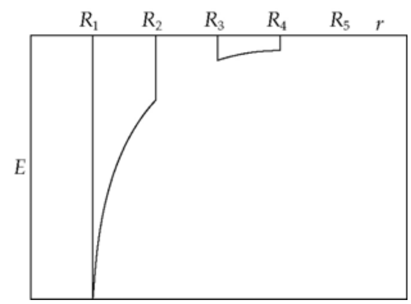
(*b*) The charge on sphere I ($-Q_0$) will induce a charge of the same magnitude but opposite sign on sphere II: $\boxed{+Q_0}$

(*c*) The induction of charge $+Q_0$ on the inner surface of sphere II will leave its outer surface with a charge of the same magnitude but opposite sign: $\boxed{-Q_0}$

(*d*) The presence of charge $-Q_0$ on the outer surface of sphere II will induce a charge of the same magnitude but opposite sign on the inner surface of sphere III: $\boxed{+Q_0}$

(*e*) The presence of charge $+Q_0$ on the inner surface of sphere III will leave the outer surface of sphere III neutral: $\boxed{0}$

(*f*) A graph of E as a function of r is shown to the right:



67 •• **[SSM]** A large, flat, nonconducting, non-uniformly charged surface lies in the $x = 0$ plane. At the origin, the surface charge density is $+3.10\ \mu\text{C/m}^2$. A small distance away from the surface on the positive x axis, the x component of the electric field is 4.65×10^5 N/C. What is E_x a small distance away from the surface on the negative x axis?

Picture the Problem Because the difference between the field just to the right of the surface $E_{x,\text{pos}}$ and the field just to the left of the surface $E_{x,\text{neg}}$ is the field due to the nonuniform surface charge, we can express $E_{x,\text{neg}}$ as the difference between $E_{x,\text{pos}}$ and σ/ϵ_0.

Express the electric field just to the left of the origin in terms of $E_{x,\text{pos}}$ and σ/ϵ_0:

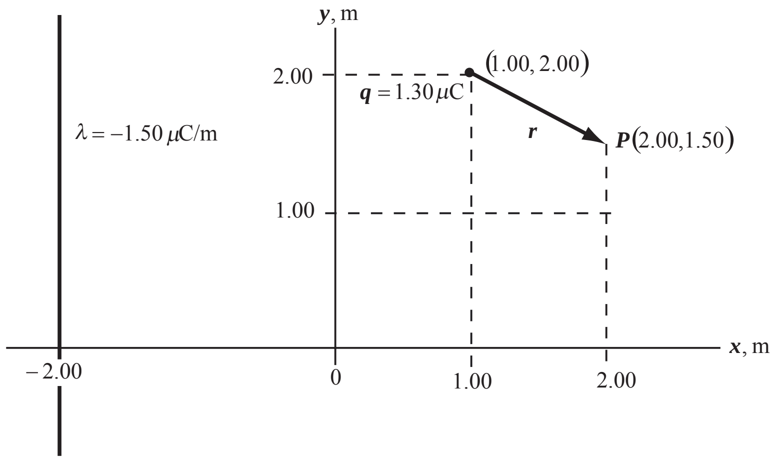
$$E_{x,\text{neg}} = E_{x,\text{pos}} - \frac{\sigma}{\epsilon_0}$$

Substitute numerical values and evaluate $E_{x,\text{neg}}$:

$$E_{x,\text{neg}} = 4.65\times10^5\ \text{N/C} - \frac{3.10\ \mu\text{C/m}^2}{8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = \boxed{115\ \text{kN/C}}$$

68 •• An infinitely long line charge that has a uniform linear charge density equal to $-1.50\ \mu$C/m lies parallel to the y axis at $x = -2.00$ m. A positive point charge that has a magnitude equal to $1.30\ \mu$C is located at $x = 1.00$ m, $y = 2.00$ m. Find the electric field at $x = 2.00$ m, $y = 1.50$ m.

Picture the Problem Let P denote the point of interest at (2.00 m, 1.50 m). The electric field at P is the sum of the electric fields due to the infinite line charge and the point charge.



Express the resultant electric field at P: $\vec{E} = \vec{E}_\lambda + \vec{E}_q$ (1)

Find the field at P due the infinite line charge:

$$\vec{E}_\lambda = \frac{2k\lambda}{r}\hat{r} = \frac{2(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(-1.50\ \mu\text{C/m})}{4.00\,\text{m}}\hat{i} = (-6.741\,\text{kN/C})\hat{i}$$

Express the field at P due the point charge: $\vec{E}_q = \frac{kq}{r^2}\hat{r}$

Referring to the diagram above, determine r and $\hat{r}$: $r = 1.118\,\text{m}$ and $\hat{r} = 0.8944\hat{i} - 0.4472\hat{j}$

Substitute and evaluate $\vec{E}_q(2.00\,\text{m}, 1.50\,\text{m})$:

$$\begin{aligned}\vec{E}_q(2.00\,\text{m},1.50\,\text{m}) &= \frac{(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.30\ \mu\text{C})}{(1.118\,\text{m})^2}(0.8944\hat{i} - 0.4472\hat{j}) \\ &= (9.348\,\text{kN/C})(0.8944\hat{i} - 0.4472\hat{j}) \\ &= (8.361\,\text{kN/C})\hat{i} - (4.180\,\text{kN/C})\hat{j}\end{aligned}$$

Substitute for $\vec{E}_\lambda$ and $\vec{E}_q$ in equation (1) and simplify to obtain:

$$\begin{aligned}\vec{E}(2.00\,\text{m},1.50\,\text{m}) &= (-6.741\,\text{kN/C})\hat{i} + (8.361\,\text{kN/C})\hat{i} - (4.180\,\text{kN/C})\hat{j}\\ &= \boxed{(1.62\,\text{kN/C})\hat{i} - (4.18\,\text{kN/C})\hat{j}}\end{aligned}$$

69 •• [SSM] A thin, non-conducting, uniformly charged spherical shell of radius R (Figure 22-44*a*) has a total positive charge of Q. A small circular plug is removed from the surface. (*a*) What is the magnitude and direction of the electric field at the center of the hole? (*b*) The plug is now put back in the hole (Figure 22-44*b*). Using the result of Part (*a*), find the electric force acting on the plug. (*c*) Using the magnitude of the force, calculate the "electrostatic pressure" (force/unit area) that tends to expand the sphere.

Picture the Problem If the patch is small enough, the field at the center of the patch comes from two contributions. We can view the field in the hole as the sum of the field from a uniform spherical shell of charge Q plus the field due to a small patch with surface charge density equal but opposite to that of the patch cut out.

(*a*) Express the magnitude of the electric field at the center of the hole:

$$E = E_{\substack{\text{spherical}\\\text{shell}}} + E_{\text{hole}}$$

Apply Gauss's law to a spherical gaussian surface just outside the given sphere:

$$E_{\substack{\text{spherical}\\\text{shell}}}\left(4\pi r^2\right) = \frac{Q_{\text{enclosed}}}{\epsilon_0} = \frac{Q}{\epsilon_0}$$

Solve for $E_{\substack{\text{spherical}\\\text{shell}}}$ to obtain:

$$E_{\substack{\text{spherical}\\\text{shell}}} = \frac{Q}{4\pi\epsilon_0 r^2}$$

The electric field due to the small hole (small enough so that we can treat it as a plane surface) is:

$$E_{\text{hole}} = \frac{-\sigma}{2\epsilon_0}$$

Substitute for $E_{\substack{\text{spherical}\\\text{shell}}}$ and E_{hole} and simplify to obtain:

$$\begin{aligned}E &= \frac{Q}{4\pi\epsilon_0 r^2} + \frac{-\sigma}{2\epsilon_0}\\ &= \frac{Q}{4\pi\epsilon_0 r^2} - \frac{Q}{2\epsilon_0\left(4\pi r^2\right)}\\ &= \boxed{\frac{Q}{8\pi\epsilon_0 r^2}}\ \text{radially outward}\end{aligned}$$

(*b*) Express the force on the patch:

$$F = qE$$

where q is the charge on the patch.

Assuming that the patch has radius *a,* express the proportion between its charge and that of the spherical shell:

$$\frac{q}{\pi a^2}=\frac{Q}{4\pi r^2} \text{ or } q=\frac{a^2}{4r^2}Q$$

Substitute for q and E in the expression for F to obtain:

$$F=\left(\frac{a^2}{4r^2}Q\right)\left(\frac{Q}{8\pi \in_0 r^2}\right)$$

$$=\boxed{\frac{Q^2a^2}{32\pi \in_0 r^4}} \text{ radially outward}$$

(*c*) The pressure is the force exerted on the patch divided by the area of the patch:

$$P=\frac{\dfrac{Q^2a^2}{32\pi \in_0 r^4}}{\pi a^2}=\boxed{\frac{Q^2}{32\pi^2 \in_0 r^4}}$$

70 •• An infinite thin sheet in the $y = 0$ plane has a uniform surface charge density $\sigma_1 = +65\ \text{nC/m}^2$. A second infinite thin sheet has a uniform charge density $\sigma_2 = +45\ \text{nC/m}^2$ and intersects the $y = 0$ plane at the z axis and makes an angle of 30º with the xz plane, as shown in Figure 22-45. Find the electric field at (*a*) $x = 6.0$ m, $y = 2.0$ m and (*b*) $x = 6.0$ m, $y = 5.0$ m.

Picture the Problem Let the numeral 1 refer to the plane with charge density σ_1 and the numeral 2 to the plane with charge density σ_2. We can find the electric field at the two points of interest by adding the electric fields due to the charge distributions of the two infinite planes.

Express the electric field at any point in space due to the charge distributions on the two planes:

$$\vec{E}=\vec{E}_1+\vec{E}_2 \qquad (1)$$

(*a*) Express the electric field at (6.0 m, 2.0 m) due to plane 1:

$$\vec{E}_1(6.0\,\text{m},2.0\,\text{m})=\frac{\sigma_1}{2\in_0}\hat{\boldsymbol{j}}=\frac{+65\,\text{nC/m}^2}{2\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}\hat{\boldsymbol{j}}=(3.67\,\text{kN/C})\hat{\boldsymbol{j}}$$

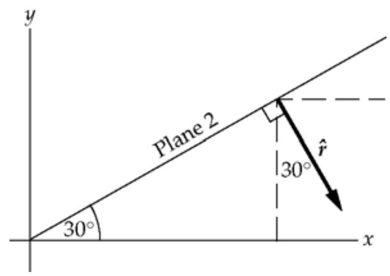
Express the electric field at (6.0 m, 2.0 m) due to plane 2:

$$\vec{E}_2(6.0\,\text{m},2.0\,\text{m})=\frac{\sigma_2}{2\in_0}\hat{\boldsymbol{r}}=\frac{+45\,\text{nC/m}^2}{2\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}\hat{\boldsymbol{r}}=(2.54\,\text{kN/C})\hat{\boldsymbol{r}}$$

where $\hat{\boldsymbol{r}}$ is a unit vector pointing from plane 2 toward the point whose coordinates are (6.0 m, 2.0 m).

Refer to the following diagram to obtain:

$$\hat{\boldsymbol{r}} = \sin 30°\hat{\boldsymbol{i}} - \cos 30°\hat{\boldsymbol{j}}$$



Substitute to obtain:

$$\begin{aligned}\vec{\boldsymbol{E}}_2(6.0\,\text{m}, 2.0\,\text{m}) &= (2.54\,\text{kN/C})(\sin 30°\hat{\boldsymbol{i}} - \cos 30°\hat{\boldsymbol{j}}) \\ &= (1.27\,\text{kN/C})\hat{\boldsymbol{i}} + (-2.20\,\text{kN/C})\hat{\boldsymbol{j}}\end{aligned}$$

Substitute for $\vec{\boldsymbol{E}}_1$ and $\vec{\boldsymbol{E}}_2$ in equation (1) to obtain:

$$\begin{aligned}\vec{\boldsymbol{E}}(6.0\,\text{m}, 2.0\,\text{m}) &= (3.67\,\text{kN/C})\hat{\boldsymbol{j}} + (1.27\,\text{kN/C})\hat{\boldsymbol{i}} + (-2.20\,\text{kN/C})\hat{\boldsymbol{j}} \\ &= \boxed{(1.3\,\text{kN/C})\hat{\boldsymbol{i}} + (1.5\,\text{kN/C})\hat{\boldsymbol{j}}}\end{aligned}$$

(*b*) Note that $\vec{\boldsymbol{E}}_1(6.0\,\text{m}, 5.0\,\text{m}) = \vec{\boldsymbol{E}}_1(6.0\,\text{m}, 2.0\,\text{m})$ so that:

$$\vec{\boldsymbol{E}}_1(6\,\text{m}, 5\,\text{m}) = \frac{\sigma}{2\in_0}\hat{\boldsymbol{j}} = \frac{65\,\text{nC/m}^2}{2(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)}\hat{\boldsymbol{j}} = (3.67\,\text{kN/C})\hat{\boldsymbol{j}}$$

Note also that $\vec{\boldsymbol{E}}_2(6.0\,\text{m}, 5.0\,\text{m}) = -\vec{\boldsymbol{E}}_2(6.0\,\text{m}, 2.0\,\text{m})$ so that:

$$\vec{\boldsymbol{E}}_2(6.0\,\text{m}, 5.0\,\text{m}) = (-1.27\,\text{kN/C})\hat{\boldsymbol{i}} + (2.20\,\text{kN/C})\hat{\boldsymbol{j}}$$

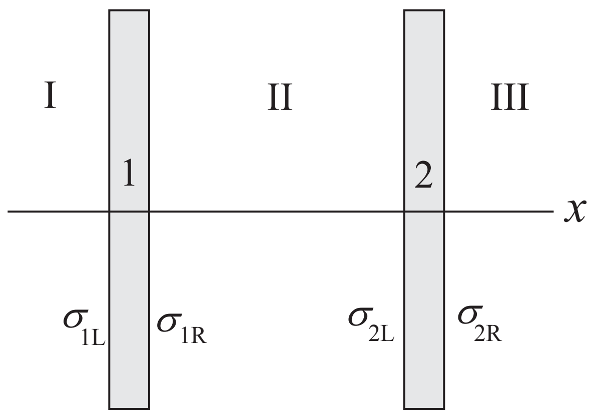
Substitute for $\vec{\boldsymbol{E}}_1$ and $\vec{\boldsymbol{E}}_2$ in equation (1) to obtain:

$$\begin{aligned}\vec{\boldsymbol{E}}(6.0\,\text{m}, 5.0\,\text{m}) &= (3.67\,\text{kN/C})\hat{\boldsymbol{j}} + (-1.27\,\text{kN/C})\hat{\boldsymbol{i}} + (2.20\,\text{kN/C})\hat{\boldsymbol{j}} \\ &= \boxed{(-1.3\,\text{kN/C})\hat{\boldsymbol{i}} + (5.9\,\text{kN/C})\hat{\boldsymbol{j}}}\end{aligned}$$

71 •• Two identical square parallel metal plates each have an area of 500 cm^2. They are separated by 1.50 cm. They are both initially uncharged. Now a charge of +1.50 nC is transferred from the plate on the left to the plate on the right and the charges then establish electrostatic equilibrium. (Neglect edge effects.) (*a*) What is the electric field between the plates at a distance of 0.25 cm from the plate on the right? (*b*) What is the electric field between the plates a

distance of 1.00 cm from the plate on the left? (*c*) What is the electric field just to the left of the plate on the left? (*d*) What is the electric field just to the right of the plate to the right?

Picture the Problem The transfer of charge from the plate on the left to the plate on the right leaves the plates with equal but opposite charges. Because the metal plates are conductors, the charge on each plate is completely on the surface facing the other plate. The symbols for the four surface charge densities are shown in the figure. The *x* component of the electric field due to the charge on surface 1L is $-\sigma_{1L}/2\epsilon_0$ at points to the left of surface 1L and is $+\sigma_{1L}/2\epsilon_0$ at points to the right of surface 1L, where the +*x* direction is to the right. Similar expressions describe the electric fields due to the other three surface charges. We can use superposition of electric fields to find the electric field in each of the three regions.



Define σ_1 and σ_2 so that:

$$\sigma_1 = \sigma_{1L} + \sigma_{1R}$$
and
$$\sigma_2 = \sigma_{2L} + \sigma_{2R}$$

(*a*) and (*b*) In the region between the plates (region II):

$$E_{x,\text{II}} = \frac{\sigma_{1L}}{2\epsilon_0} + \frac{\sigma_{1R}}{2\epsilon_0} - \frac{\sigma_{2L}}{2\epsilon_0} - \frac{\sigma_{2R}}{2\epsilon_0}$$
$$= 0 + \frac{\sigma_1}{2\epsilon_0} - \frac{\sigma_2}{2\epsilon_0} - 0 = \frac{\sigma_1 - \sigma_2}{\epsilon_0}$$

Let $\sigma_2 = -\sigma_1 = \sigma$. Then:

$$\sigma_1 - \sigma_2 = -\sigma - \sigma = -2\sigma$$

Substituting for $\sigma_1 - \sigma_2$ and using the definition of σ yields:

$$E_{x,\text{II}} = \frac{-2\sigma}{\epsilon_0} = -\frac{Q}{A\epsilon_0}$$

Substitute numerical values and evaluate $E_{x,\text{II}}$:

$$E_{x,\text{II}} = -\frac{1.50\,\text{nC}}{\left(8.854\times10^{-12}\,\dfrac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(500\times10^{-6}\,\text{m}^2\right)} = \boxed{339\text{ kN/C}} \text{ toward the left}$$

(*c*) The electric field strength just to the left of the plate on the left (region I) is given by:

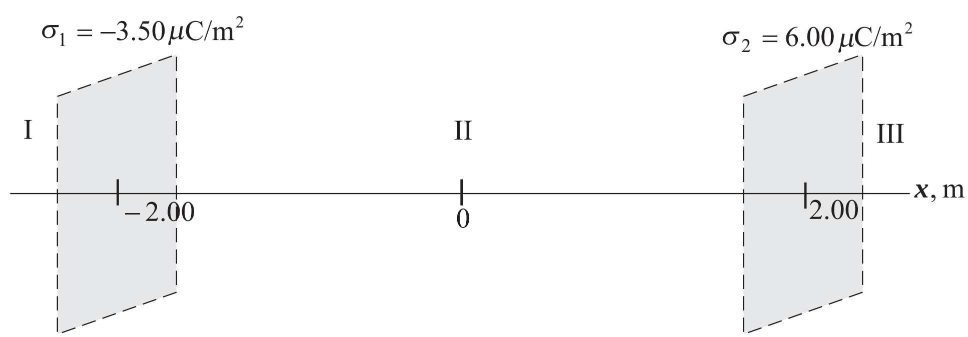
$$\begin{aligned} E_{x,\text{I}} &= -\frac{\sigma_{1\text{L}}}{2\in_0} - \frac{\sigma_{1\text{R}}}{2\in_0} - \frac{\sigma_{2\text{L}}}{2\in_0} - \frac{\sigma_{2\text{R}}}{2\in_0} \\ &= 0 - \frac{\sigma_1}{2\in_0} - \frac{\sigma_2}{2\in_0} - 0 \\ &= -\frac{-\sigma}{2\in_0} - \frac{\sigma}{2\in_0} = \boxed{0} \end{aligned}$$

(*d*) The electric field strength just to the right of the plate on the right (region III) is given by:

$$\begin{aligned} E_{x,\text{III}} &= \frac{\sigma_{1\text{L}}}{2\in_0} + \frac{\sigma_{1\text{R}}}{2\in_0} + \frac{\sigma_{2\text{L}}}{2\in_0} + \frac{\sigma_{2\text{R}}}{2\in_0} \\ &= 0 + \frac{\sigma_1}{2\in_0} + \frac{\sigma_2}{2\in_0} - 0 \\ &= \frac{-\sigma}{2\in_0} + \frac{\sigma}{2\in_0} = \boxed{0} \end{aligned}$$

72 •• Two infinite nonconducting uniformly charged planes lie parallel to each other and to the *yz* plane. One is at $x = -2.00$ m and has a surface charge density of $-3.50\ \mu\text{C/m}^2$. The other is at $x = 2.00$ m and has a surface charge density of $6.00\ \mu\text{C/m}^2$. Find the electric field in the region (*a*) $x < -2.00$ m, (*b*) $-2.00\text{ m} < x < 2.00$ m, and (*c*) $x > 2.00$ m.

Picture the Problem Let the numeral 1 refer to the infinite plane at $x = -2.00$ m and the numeral 2 to the plane at $x = 2.00$ m and let I, II, and III identify the regions to the left of plane 1, between the planes, and to the right of plane 2, respectively. We can use the expression for the electric field of in infinite plane of charge to express the electric field due to each plane of charge in each of the three regions. Their sum will be the resultant electric field in each region.



The resultant electric field is the sum of the fields due to planes 1 and 2:

$$\vec{E} = \vec{E}_1 + \vec{E}_2 \qquad (1)$$

(*a*) The field due to plane 1 in region I is given by:

$$\vec{E}_1 = \frac{\sigma_1}{2\epsilon_0}\left(-\hat{i}\right)$$

The field due to plane 2 in region I is given by:

$$\vec{E}_2 = \frac{\sigma_2}{2\epsilon_0}\left(-\hat{i}\right)$$

Substitute for $\vec{E}_1$ and $\vec{E}_2$ in equation (1) and simplify to obtain:

$$\vec{E} = \frac{\sigma_1}{2\epsilon_0}\left(-\hat{i}\right) + \frac{\sigma_2}{2\epsilon_0}\left(-\hat{i}\right) = -\frac{\sigma_1 + \sigma_2}{2\epsilon_0}\hat{i}$$

Substitute numerical values and evaluate $\vec{E}$:

$$\vec{E} = -\frac{-3.50\,\mu\text{C/m}^2 + 6.00\,\mu\text{C/m}^2}{2\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}\hat{i} = \boxed{\left(-141\,\text{kN/C}\right)\hat{i}}$$

(*b*) The field due to plane 1 in region II is given by:

$$\vec{E}_1 = \frac{\sigma_1}{2\epsilon_0}\hat{i}$$

The field due to plane 2 in region II is given by:

$$\vec{E}_2 = \frac{\sigma_2}{2\epsilon_0}\left(-\hat{i}\right)$$

Substitute for $\vec{E}_1$ and $\vec{E}_2$ in equation (1) and simplify to obtain:

$$\vec{E} = \frac{\sigma_1}{2\epsilon_0}\left(\hat{i}\right) + \frac{\sigma_2}{2\epsilon_0}\left(-\hat{i}\right) = \frac{\sigma_1 - \sigma_2}{2\epsilon_0}\hat{i}$$

Substitute numerical values and evaluate $\vec{E}$:

$$\vec{E} = -\frac{-3.50\,\mu\text{C/m}^2 - 6.00\,\mu\text{C/m}^2}{2\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}\hat{i} = \boxed{\left(-536\,\text{kN/C}\right)\hat{i}}$$

(*c*) The field due to plane 1 in region III is given by:

$$\vec{E}_1 = \frac{\sigma_1}{2\epsilon_0}\hat{i}$$

The field due to plane 2 in region III is given by:

$$\vec{E}_2 = \frac{\sigma_2}{2\epsilon_0}\hat{i}$$

Substitute for $\vec{E}_1$ and $\vec{E}_2$ in equation (1) and simplify to obtain:

$$\vec{E} = \frac{\sigma_1}{2\epsilon_0}\left(\hat{i}\right) + \frac{\sigma_2}{2\epsilon_0}\left(\hat{i}\right) = \frac{\sigma_1 + \sigma_2}{2\epsilon_0}\hat{i}$$

Substitute numerical values and evaluate $\vec{E}$:

$$\vec{E} = -\frac{-3.50\ \mu\text{C/m}^2 + 6.00\ \mu\text{C/m}^2}{2\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}\hat{i}$$

$$= \boxed{(141\,\text{kN/C})\hat{i}}$$

73 ••• **[SSM]** A quantum-mechanical treatment of the hydrogen atom shows that the electron in the atom can be treated as a smeared-out distribution of negative charge of the form $\rho(r) = -\rho_0 e^{-2r/a}$. Here r represents the distance from the center of the nucleus and a represents the first *Bohr radius* which has a numerical value of 0.0529 nm. Recall that the nucleus of a hydrogen atom consists of just one proton and treat this proton as a positive point charge. (*a*) Calculate ρ_0, using the fact that the atom is neutral. (*b*) Calculate the electric field at any distance r from the nucleus.

Picture the Problem Because the atom is uncharged, we know that the integral of the electron's charge distribution over all of space must equal its charge q_e. Evaluation of this integral will lead to an expression for ρ_0. In (*b*) we can express the resultant electric field at any point as the sum of the electric fields due to the proton and the electron cloud.

(*a*) Because the atom is uncharged, the integral of the electron's charge distribution over all of space must equal its charge e:

$$e = \int_0^\infty \rho(r)dV = \int_0^\infty \rho(r)4\pi r^2 dr$$

Substitute for $\rho(r)$ and simplify to obtain:

$$e = -\int_0^\infty \rho_0 e^{-2r/a}4\pi r^2 dr$$

$$= -4\pi\rho_0\int_0^\infty r^2 e^{-2r/a}dr$$

Use integral tables or integration by parts to obtain:

$$\int_0^\infty r^2 e^{-2r/a}dr = \frac{a^3}{4}$$

Substitute for $\int_0^\infty r^2 e^{-2r/a}dr$ to obtain:

$$e = -4\pi\rho_0\left(\frac{a^3}{4}\right) = -\pi a^3\rho_0$$

Solving for ρ_0 yields:

$$\rho_0 = \boxed{-\frac{e}{\pi a^3}}$$

(*b*) The field will be the sum of the field due to the proton and that of the electron charge cloud:

$$E = E_{\text{p}} + E_{\text{cloud}}$$

Express the field due to the electron cloud:

$$E_{\text{cloud}}(r)=\frac{kQ(r)}{r^2}$$

where $Q(r)$ is the net negative charge enclosed a distance r from the proton.

Substitute for E_p and E_{cloud} to obtain:

$$E(r)=\frac{ke}{r^2}+\frac{kQ(r)}{r^2} \qquad (1)$$

$Q(r)$ is given by:

$$Q(r)=\int_0^r 4\pi r'^2\rho(r')dr'$$

$$=4\pi\int_0^r r'^2\rho_0 e^{-2r'/a}dr'$$

From Part (a), $\rho_0=\dfrac{-e}{\pi a^3}$:

$$Q(r)=4\pi\left(\frac{-e}{\pi a^3}\right)\int_0^r r'^2 e^{-2r'/a}dr'$$

$$=\frac{-4e}{a^3}\int_0^r r'^2 e^{-2r'/a}dr'$$

From a table of integrals:

$$\int_0^r x^2 e^{-2x/a}dx=\tfrac{1}{4}e^{-2r/a}a\left[\left(e^{-2r/a}-1\right)a^2-2ar-2r^2\right]$$

$$=\tfrac{1}{4}e^{-2r/a}a^3\left[\left(e^{-2r/a}-1\right)-2\frac{r}{a}-2\frac{r^2}{a^2}\right]$$

$$=\frac{a^3}{4}\left[\left(1-e^{-2r/a}\right)-2e^{-2r/a}\left(\frac{r}{a}+\frac{r^2}{a^2}\right)\right]$$

Substituting for $\int_0^r r'^2 e^{-2r'/a}dr'$ in the expression for $Q(r)$ and simplifying yields:

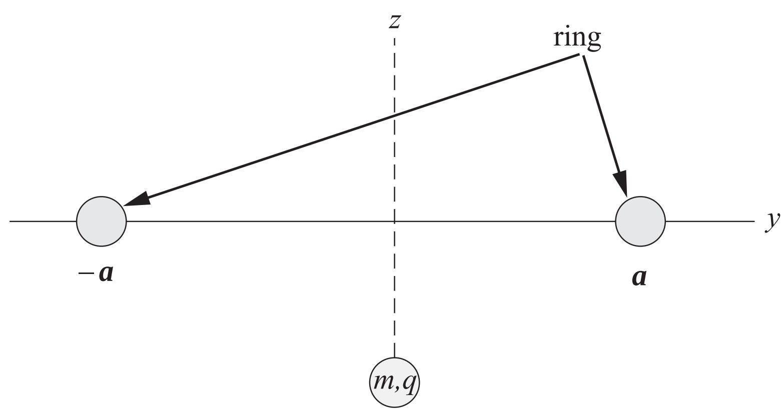
$$Q(r)=\frac{-e}{4}\left[\left(1-e^{-2r/a}\right)-2e^{-2r/a}\left(\frac{r}{a}+\frac{r^2}{a^2}\right)\right]$$

Substitute for $Q(r)$ in equation (1) and simplify to obtain:

$$E(r) = \frac{ke}{r^2} - \frac{ke}{4r^2}\left[\left(1-e^{-2r/a}\right) - 2e^{-2r/a}\left(\frac{r}{a}+\frac{r^2}{a^2}\right)\right]$$
$$= \boxed{\frac{ke}{r^2}\left(1-\frac{1}{4}\left[\left(1-e^{-2r/a}\right) - 2e^{-2r/a}\left(\frac{r}{a}+\frac{r^2}{a^2}\right)\right]\right)}$$

74 •• A uniformly charged ring has a radius *a,* lies in a horizontal plane, and has a negative charge given by –*Q*. A small particle of mass *m* has a positive charge given by *q*. The small particle is located on the axis of the ring. (*a*) What is the minimum value of *q/m* such that the particle will be in equilibrium under the action of gravity and the electrostatic force? (*b*) If *q/m* is twice the value calculated in Part (*a*), where will the particle be when it is in equilibrium? Express your answer in terms of *a.*

Picture the Problem We can apply the condition for translational equilibrium to the particle and use the expression for the electric field on the axis of a ring charge to obtain an expression for *q/m*. Doing so will lead us to the conclusion that *q/m* will be a minimum when E_z is a maximum and that $z = -a/\sqrt{2}$ maximizes E_z.



(*a*) Apply $\sum F_z = 0$ to the particle:

$$qE_z - mg = 0 \Rightarrow \frac{q}{m} = \frac{g}{E_z} \qquad (1)$$

Note that this result tells us that the minimum value of *q/m* will be where the field due to the ring is greatest.

Express the electric field along the *z* axis due to the ring of charge:

$$E_z = \frac{kQz}{\left(z^2+a^2\right)^{3/2}}$$

Differentiate this expression with respect to z to obtain:

$$\frac{dE_x}{dz} = kQ\frac{d}{dz}\left[\frac{z}{\left(z^2+a^2\right)^{3/2}}\right] = kQ\frac{\left(z^2+a^2\right)^{3/2} - z\frac{d}{dx}\left(z^2+a^2\right)^{3/2}}{\left(z^2+a^2\right)^3}$$

$$= kQ\frac{\left(z^2+a^2\right)^{3/2} - z\left(\frac{3}{2}\right)\left(z^2+a^2\right)^{1/2}(2z)}{\left(z^2+a^2\right)^3} = kQ\frac{\left(z^2+a^2\right)^{3/2} - 3z^2\left(z^2+a^2\right)^{1/2}}{\left(z^2+a^2\right)^3}$$

Set this expression equal to zero for extrema and simplify:

$$\frac{\left(z^2+a^2\right)^{3/2} - 3z^2\left(z^2+a^2\right)^{1/2}}{\left(z^2+a^2\right)^3} = 0,$$

$$\left(z^2+a^2\right)^{3/2} - 3z^2\left(z^2+a^2\right)^{1/2} = 0,$$

and

$$z^2 + a^2 - 3z^2 = 0$$

Solve for z to obtain:

$$z = \pm\frac{a}{\sqrt{2}}$$

as candidates for maxima or minima.

You can either plot a graph of E_z or evaluate its second derivative at these points to show that it is a maximum at:

$$z = -\frac{a}{\sqrt{2}}$$

Substitute to obtain an expression $E_{z,\max}$:

$$E_{z,\max} = \left|\frac{kQ\left(-\frac{a}{\sqrt{2}}\right)}{\left(\left(-\frac{a}{\sqrt{2}}\right)^2 + a^2\right)^{3/2}}\right| = \frac{2kQ}{\sqrt{27}a^2}$$

Substitute in equation (1) to obtain:

$$\frac{q}{m} = \boxed{\frac{\sqrt{27}ga^2}{2kQ}}$$

(*b*) If q/m is twice as great as in (*a*), then the electric field should be half its value in (*a*), that is:

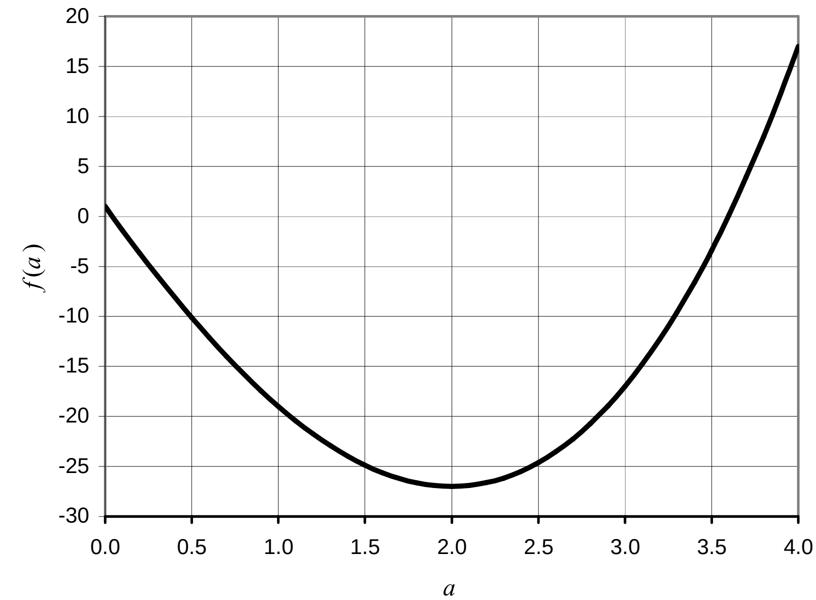
$$\frac{kQ}{\sqrt{27}a^2} = \frac{kQz}{\left(z^2+a^2\right)^{3/2}}$$

or

$$\frac{1}{27a^4} = \frac{z^2}{a^6\left(1+\frac{z^2}{a^2}\right)^3}$$

Let $u = z^2/a^2$ and simplify to obtain: $u^3 + 3u^2 - 24u + 1 = 0$

The following graph of $f(u) = u^3 + 3u^2 - 24u + 1$ was plotted using a spreadsheet program.

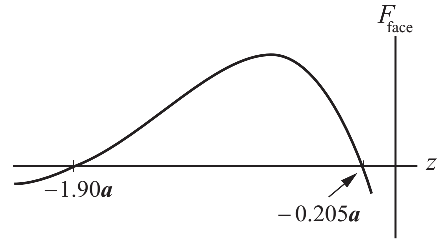


Use your graphing calculator or trial-and-error methods to obtain: $u = 0.04189$ and $u = 3.596$

The corresponding z values are: $z = -0.205a$ and $z = -1.90a$

The condition for a stable equilibrium position is that the particle, when displaced from its equilibrium position, experiences a restoring force; that is, a force that acts toward the equilibrium position. When the particle in this problem is just above its equilibrium position the net force on it must be downward and when it is just below the equilibrium position the net force on it must be upward. Note that the electric force is zero at the origin, so the net force there is downward and remains downward to the first equilibrium position as the weight force exceeds the electric force in this interval. The net force is upward between the first and second equilibrium positions as the electric force exceeds the weight force. The net force is downward below the second equilibrium position as the weight force exceeds the electric force. Thus, the first (higher) equilibrium position is stable and the second (lower) equilibrium position is unstable.

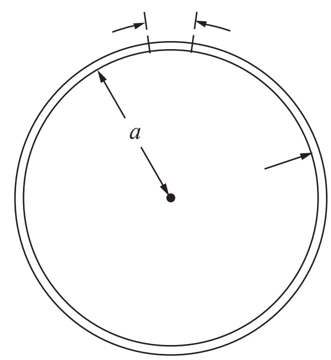
You might also find it instructive to use your graphing calculator to plot a graph of the electric force (the gravitational force is constant and only shifts the graph of the total force downward). Doing so will produce a graph similar to the one shown in the sketch to the right.



Note that the slope of the graph is negative on both sides of $-0.205a$ whereas it is positive on both sides of $-1.90a$; further evidence that $-0.205a$ is a position of stable equilibrium and $-1.90a$ a position of unstable equilibrium.

75 •• A long, thin, non-conducting plastic rod is bent into a circular loop that has a radius a. Between the ends of the rod a short gap of length ℓ, where $\ell << a$, remains. A positive charge of magnitude Q is evenly distributed on the loop. (a) What is the direction of the electric field at the center of the loop? Explain your answer. (b) What is the magnitude of the electric field at the center of the loop?

Picture the Problem The loop with the small gap is equivalent to a closed loop and a charge of $-Q\ell/(2\pi R)$ at the gap. The field at the center of a closed loop of uniform line charge is zero. Thus the field is entirely due to the charge $-Q\ell/(2\pi R)$.



(a) Express the field at the center of the loop:

$$\vec{E}_{\text{center}} = \vec{E}_{\text{loop}} + \vec{E}_{\text{gap}} \qquad (1)$$

Relate the field at the center of the loop to the charge in the gap:

$$\vec{E}_{\text{gap}} = -\frac{kq}{a^2}\hat{\boldsymbol{r}}$$

Use the definition of linear charge density to relate the charge in the gap to the length of the gap:

$$\lambda = \frac{q}{\ell} = \frac{Q}{2\pi a} \Rightarrow q = \frac{Q\ell}{2\pi a}$$

Substitute for q to obtain:

$$\vec{E}_{\text{gap}} = -\frac{kQ\ell}{2\pi a^3}\hat{\boldsymbol{r}}$$

Substituting in equation (1) yields:

$$\vec{E}_{\text{center}} = 0 - \frac{kQ\ell}{2\pi a^3}\hat{r} = -\frac{kQ\ell}{2\pi a^3}\hat{r}$$

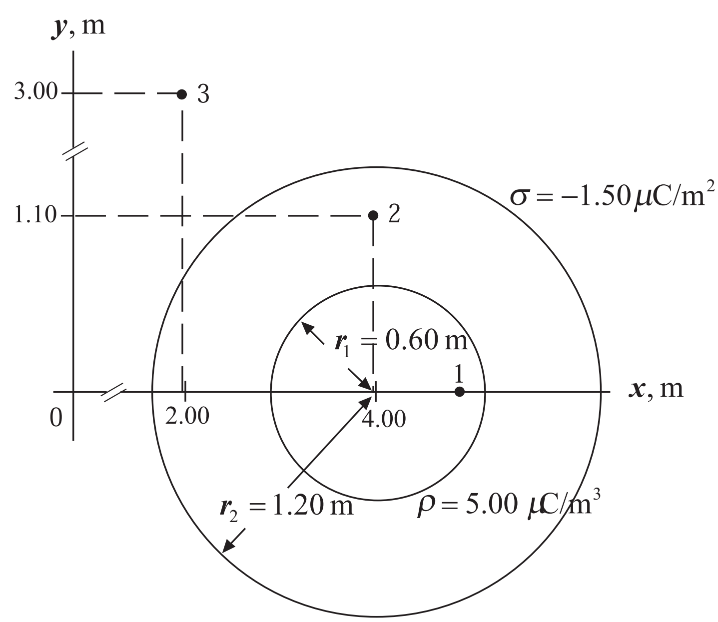
If Q is positive, the field at the origin points radially outward toward the gap.

(*b*) From our result in (*a*) we see that the magnitude of $\vec{E}_{\text{center}}$ is:

$$E_{\text{center}} = \boxed{\frac{kQ\ell}{2\pi a^3}}$$

76 •• A non-conducting solid sphere that is 1.20 m in diameter and has its center on the x axis at x = 4.00 m has a uniform volume charge of density of +5.00 μC/m^3. Concentric with the sphere is a thin non-conducting spherical shell that has a diameter of 2.40 m and a uniform surface charge density of –1.50 μC/m^2. Calculate the magnitude and direction of the electric field at (*a*) x = 4.50 m, y = 0, (*b*) x = 4.00 m, y = 1.10 m, and (*c*) x = 2.00 m, y = 3.00 m.

Picture the Problem We can find the electric fields at the three points of interest, labeled 1, 2, and 3 in the diagram, by adding the electric fields due to the charge distributions on the nonconducting sphere and the spherical shell.



Express the electric field due to the nonconducting sphere and the spherical shell at any point in space:

$$\vec{E} = \vec{E}_{\text{sphere}} + \vec{E}_{\text{shell}} \qquad (1)$$

(*a*) Because (4.50 m, 0) is inside the spherical shell:

$$\vec{E}_{\text{shell}}(4.50\,\text{m},0) = 0$$

Apply Gauss's law to a spherical surface inside the nonconducting sphere to obtain:

$$\vec{E}_{\text{sphere}}(r)=\frac{4\pi}{3}k\rho r\hat{\boldsymbol{i}}$$

Evaluate $\vec{E}_{\text{sphere}}(0.50\,\text{m})$:

$$\begin{aligned}\vec{E}_{\text{sphere}}(0.50\,\text{m})&=\frac{4\pi}{3}\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(5.00\,\mu\text{C/m}^2\right)(0.50\,\text{m})\hat{\boldsymbol{i}}\\&=(94.1\,\text{kN/C})\hat{\boldsymbol{i}}\end{aligned}$$

Substitute in equation (1) to obtain:

$$\begin{aligned}\vec{E}(4.50\,\text{m},0)&=(94.1\,\text{kN/C})\hat{\boldsymbol{i}}+0\\&=(94.1\,\text{kN/C})\hat{\boldsymbol{i}}\end{aligned}$$

Find the magnitude and direction of $\vec{E}(4.50\,\text{m},0)$:

$$E(4.50\,\text{m},0)=\boxed{94\,\text{kN/C}}$$

and

$$\theta=\boxed{0°}$$

(*b*) Because (4.00 m, 1.10 m) is inside the spherical shell:

$$\vec{E}_{\text{shell}}(4.00\,\text{m},1.10\,\text{m})=0$$

Evaluate $\vec{E}_{\text{sphere}}(1.10\,\text{m})$:

$$\begin{aligned}\vec{E}_{\text{sphere}}(1.10\,\text{m})&=\frac{4\pi\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(5.00\,\mu\text{C/m}^2\right)(0.600\,\text{m})^3}{3(1.10\,\text{m})^2}\hat{\boldsymbol{j}}\\&=(33.6\,\text{kN/C})\hat{\boldsymbol{j}}\end{aligned}$$

Substitute in equation (1) to obtain:

$$\begin{aligned}\vec{E}(4.00\,\text{m},1.10\,\text{m})&=(33.6\,\text{kN/C})\hat{\boldsymbol{j}}+0\\&=(33.6\,\text{kN/C})\hat{\boldsymbol{j}}\end{aligned}$$

Find the magnitude and direction of $\vec{E}(4.00\,\text{m},1.10\,\text{m})$:

$$E(4.00\,\text{m},1.10\,\text{m})=\boxed{33.6\,\text{kN/C}}$$

and

$$\theta=\boxed{90°}$$

(*c*) Because (2.00 m, 3.00 m) outside the spherical shell:

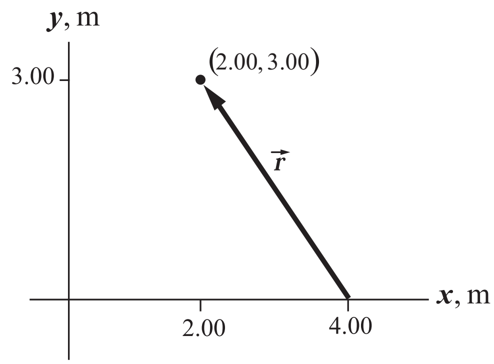
$$\vec{E}_{\text{shell}}(r)=\frac{kQ_{\text{shell}}}{r^2}\hat{\boldsymbol{r}}$$

where $\hat{\boldsymbol{r}}$ is a unit vector pointing from (4.00 m, 0) to (2.00 m, 3.00 m).

Evaluate Q_{shell}:

$$Q_{\text{shell}} = \sigma A_{\text{shell}} = 4\pi\left(-1.50\,\mu\text{C/m}^2\right)\left(1.20\,\text{m}\right)^2 = -27.14\,\mu\text{C}$$

Refer to the following diagram to find $\hat{\boldsymbol{r}}$ and r:



$r = 3.606\,\text{m}$

and

$\hat{\boldsymbol{r}} = -0.5547\hat{\boldsymbol{i}} + 0.8321\hat{\boldsymbol{j}}$

Substitute numerical values and evaluate $\vec{E}_{\text{shell}}(2.00\,\text{m}, 3.00\,\text{m})$:

$$\vec{E}_{\text{shell}}(3.606\,\text{m}) = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(-27.14\,\mu\text{C}\right)}{\left(3.606\,\text{m}\right)^2}\hat{\boldsymbol{r}}$$
$$= \left(-18.77\,\text{kN/C}\right)\left(-0.5547\hat{\boldsymbol{i}} + 0.8321\hat{\boldsymbol{j}}\right)$$
$$= \left(10.41\,\text{kN/C}\right)\hat{\boldsymbol{i}} + \left(-15.61\,\text{kN/C}\right)\hat{\boldsymbol{j}}$$

Express the electric field due to the charged nonconducting sphere at a distance r from its center that is greater than its radius:

$$\vec{E}_{\text{sphere}}(r) = \frac{kQ_{\text{sphere}}}{r^2}\hat{\boldsymbol{r}}$$

Find the charge on the sphere:

$$Q_{\text{sphere}} = \rho V_{\text{sphere}} = \frac{4\pi}{3}\left(5.00\,\mu\text{C/m}^2\right)\left(0.600\,\text{m}\right)^3 = 4.524\,\mu\text{C}$$

Evaluate $\vec{E}_{\text{sphere}}(3.61\,\text{m})$:

$$\vec{E}_{\text{sphere}}(2.00\,\text{m}, 3.00\,\text{m}) = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(4.524\,\mu\text{C}\right)}{\left(3.606\,\text{m}\right)^2}\hat{\boldsymbol{r}} = \left(3.128\,\text{kN/C}\right)\hat{\boldsymbol{r}}$$
$$= \left(3.128\,\text{kN/C}\right)\left(-0.5547\hat{\boldsymbol{i}} + 0.8321\hat{\boldsymbol{j}}\right)$$
$$= \left(-1.735\,\text{kN/C}\right)\hat{\boldsymbol{i}} + \left(2.602\,\text{kN/C}\right)\hat{\boldsymbol{j}}$$

Substitute in equation (1) to obtain:

$$\begin{aligned}\vec{E}(2.00\,\text{m},3.00\,\text{m}) &= (10.41\,\text{kN/C})\hat{i} + (-15.61\,\text{kN/C})\hat{j} + (-1.735\,\text{kN/C})\hat{i} \\ &\qquad + (2.602\,\text{kN/C})\hat{j} \\ &= (8.675\,\text{kN/C})\hat{i} + (-13.01\,\text{kN/C})\hat{j}\end{aligned}$$

Find the magnitude and direction of $\vec{E}(2.00\,\text{m},3.00\,\text{m})$:

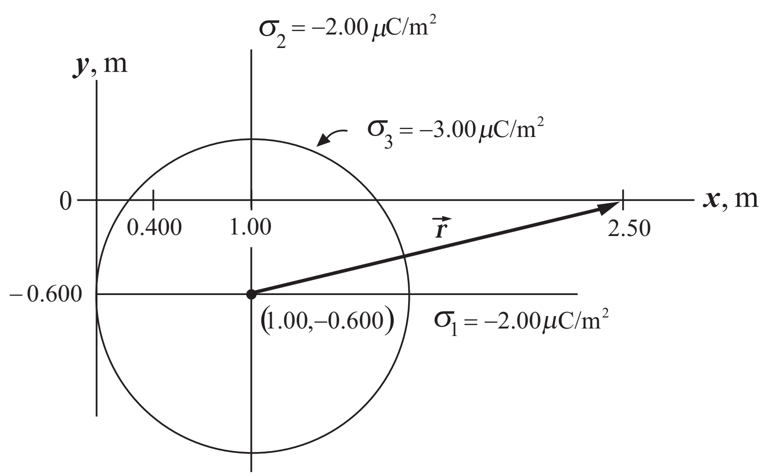
$$E(2.00\,\text{m},3.00\,\text{m}) = \sqrt{(8.675\,\text{kN/C})^2 + (-13.01\,\text{kN/C})^2} = \boxed{15.6\,\text{kN/C}}$$

and

$$\theta = \tan^{-1}\left(\frac{-13.01\,\text{kN/C}}{8.675\,\text{kN/C}}\right) = \boxed{304°}$$

77 •• An infinite non-conducting plane sheet of charge that has a surface charge density + 3.00 μC/m^2 lies in the y = –0.600 m plane. A second infinite non-conducting plane sheet of charge that has a surface charge density of –2.00 μC/m^2 lies in the x = 1.00 m plane. Lastly, a non-conducting thin spherical shell of radius of 1.00 m and that has its center in the z = 0 plane at the intersection of the two charged planes has a surface charge density of –3.00 μC/m^2. Find the magnitude and direction of the electric field on the x axis at (a) x = 0.400 m and (b) x = 2.50 m.

Picture the Problem Let the numeral 1 refer to the infinite plane whose charge density is σ_1 and the numeral 2 to the infinite plane whose charge density is σ_2. We can find the electric fields at the two points of interest by adding the electric fields due to the charge distributions on the infinite planes and the sphere.



Express the electric field due to the infinite planes and the sphere at any point in space:

$$\vec{E} = \vec{E}_{\text{sphere}} + \vec{E}_1 + \vec{E}_2 \qquad (1)$$

(*a*) Because (0.400 m, 0) is inside the sphere:

$$\vec{E}_{\text{sphere}}(0.400\,\text{m},0) = 0$$

Find the field at (0.400 m, 0) due to plane 1:

$$\vec{E}_1(0.400\,\text{m},0) = \frac{\sigma_1}{2\,\epsilon_0}\hat{\boldsymbol{j}} = \frac{3.00\,\mu\text{C/m}^2}{2(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)}\hat{\boldsymbol{j}} = (169.4\,\text{kN/C})\hat{\boldsymbol{j}}$$

Find the field at (0.400 m, 0) due to plane 2:

$$\vec{E}_2(0.400\,\text{m},0) = \frac{\sigma_2}{2\,\epsilon_0}\left(-\hat{\boldsymbol{i}}\right) = \frac{-2.00\,\mu\text{C/m}^2}{2(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)}\left(-\hat{\boldsymbol{i}}\right) = (112.9\,\text{kN/C})\hat{\boldsymbol{i}}$$

Substitute in equation (1) to obtain:

$$\vec{E}(0.400\,\text{m},0) = 0 + (169.4\,\text{kN/C})\hat{\boldsymbol{j}} + (112.9\,\text{kN/C})\hat{\boldsymbol{i}} = (112.9\,\text{kN/C})\hat{\boldsymbol{i}} + (169.4\,\text{kN/C})\hat{\boldsymbol{j}}$$

Find the magnitude and direction of $\vec{E}(0.400\,\text{m},0)$:

$$E(0.400\,\text{m},0) = \sqrt{(112.9\,\text{kN/C})^2 + (169.4\,\text{kN/C})^2} = 203.6\,\text{kN/C} = \boxed{204\,\text{kN/C}}$$

and

$$\theta = \tan^{-1}\left(\frac{169.4\,\text{kN/C}}{112.9\,\text{kN/C}}\right) = 56.31° = \boxed{56.3°}$$

(*b*) Because (2.50 m, 0) is outside the sphere:

$$\vec{E}_{\text{sphere}}(0.400\,\text{m},0) = \frac{kQ_{\text{sphere}}}{r^2}\hat{\boldsymbol{r}}$$

where $\hat{\boldsymbol{r}}$ is a unit vector pointing from (1.00 m, −0.600 m) to (2.50 m, 0).

Evaluate Q_{sphere}:

$$\begin{aligned} Q_{\text{sphere}} &= \sigma A_{\text{sphere}} = 4\pi\sigma R^2 \\ &= 4\pi(-3.00\,\mu\text{C/m}^2)(1.00\,\text{m})^2 \\ &= -37.70\,\mu\text{C} \end{aligned}$$

Referring to the diagram above, determine r and $\hat{\boldsymbol{r}}$:

$r = 1.616\,\text{m}$

and

$\hat{\boldsymbol{r}} = 0.9285\hat{\boldsymbol{i}} + 0.3714\hat{\boldsymbol{j}}$

Substitute and evaluate $\vec{\boldsymbol{E}}_{\text{sphere}}(2.50\,\text{m},0)$:

$$\vec{\boldsymbol{E}}_{\text{sphere}}(2.50\,\text{m},0) = \frac{(8.988\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2)(-37.70\,\mu\text{C})}{(1.616\,\text{m})^2}\hat{\boldsymbol{r}}$$
$$= (-129.8\,\text{kN/C})(0.9285\hat{\boldsymbol{i}} + 0.3714\hat{\boldsymbol{j}})$$
$$= (-120.5\,\text{kN/C})\hat{\boldsymbol{i}} + (-48.22\,\text{kN/C})\hat{\boldsymbol{j}}$$

Find the field at (2.50 m, 0) due to plane 1:

$$\vec{\boldsymbol{E}}_1(2.50\,\text{m},0) = \frac{\sigma_1}{2\epsilon_0}\hat{\boldsymbol{j}} = \frac{3.00\,\mu\text{C/m}^2}{2(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)}\hat{\boldsymbol{j}} = (169.4\,\text{kN/C})\hat{\boldsymbol{j}}$$

Find the field at (2.50 m, 0) due to plane 2:

$$\vec{\boldsymbol{E}}_2(2.50\,\text{m},0) = \frac{\sigma_2}{2\epsilon_0}\hat{\boldsymbol{i}} = \frac{-2.00\,\mu\text{C/m}^2}{2(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)}\hat{\boldsymbol{i}} = (-112.9\,\text{kN/C})\hat{\boldsymbol{i}}$$

Substitute in equation (1) to obtain:

$$\vec{\boldsymbol{E}}(0.400\,\text{m},0) = (-120.5\,\text{kN/C})\hat{\boldsymbol{i}} + (-48.19\,\text{kN/C})\hat{\boldsymbol{j}} + (169.4\,\text{kN/C})\hat{\boldsymbol{j}}$$
$$+ (-112.9\,\text{kN/C})\hat{\boldsymbol{i}}$$
$$= (-233.5\,\text{kN/C})\hat{\boldsymbol{i}} + (121.2\,\text{kN/C})\hat{\boldsymbol{j}}$$

Find the magnitude and direction of $\vec{\boldsymbol{E}}(2.50\,\text{m},0)$:

$$E(2.50\,\text{m},0) = \sqrt{(-233.5\,\text{kN/C})^2 + (121.2\,\text{kN/C})^2} = \boxed{263\,\text{kN/C}}$$

and

$$\theta = \tan^{-1}\left(\frac{121.2\,\text{kN/C}}{-233.5\,\text{kN/C}}\right) = \boxed{153^\circ}$$

78 •• An infinite non-conducting plane sheet lies in the $x = 2.00$ m plane and has a uniform surface charge density of $+2.00\ \mu\text{C/m}^2$. An infinite non-conducting line charge of uniform linear charge density 4.00 μC/m passes through the origin at an angle of 45.0º with the x axis in the xy plane. A solid non-conducting sphere

of volume charge density $-6.00\ \mu\text{C/m}^3$ and radius 0.800 m is centered on the x axis at $x = 1.00$ m. Calculate the magnitude and direction of the electric field in the $z = 0$ plane at $x = 1.50$ m, $y = 0.50$ m.

Picture the Problem Let P represent the point of interest at (1.50 m, 0.50 m). We can find the electric field at P by adding the electric fields due to the infinite plane, the infinite line, and the sphere. Once we've expressed the field at P in vector form, we can find its magnitude and direction.

Express the electric field at P:

$$\vec{E} = \vec{E}_{\text{plane}} + \vec{E}_{\text{line}} + \vec{E}_{\text{sphere}}$$

Find $\vec{E}_{\text{plane}}$ at P:

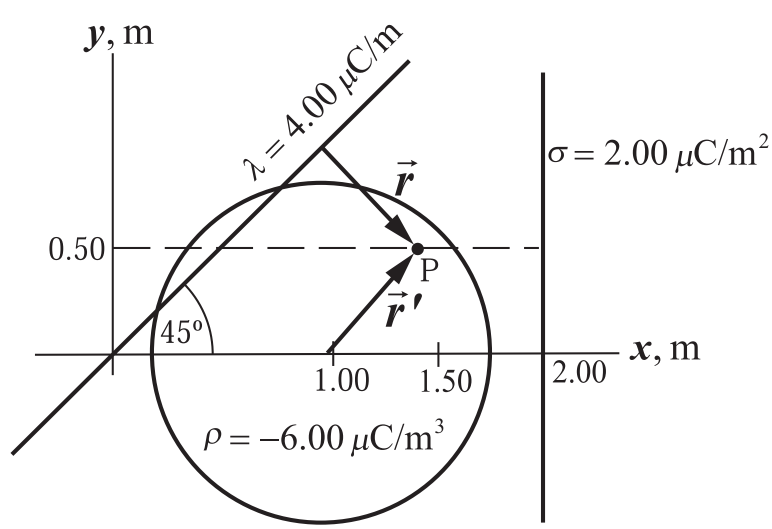
$$\vec{E}_{\text{plane}} = -\frac{\sigma}{2\in_0}\hat{i} = -\frac{2.00\ \mu\text{C/m}^2}{2\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}\hat{i} = (-112.9\ \text{kN/C})\hat{i}$$

Express $\vec{E}_{\text{line}}$ at P:

$$\vec{E}_{\text{line}} = \frac{2k\lambda}{r}\hat{r}$$

Refer to the following figure to obtain:

$$\vec{r} = (0.50\,\text{m})\hat{i} - (0.50\,\text{m})\hat{j} \text{ and } \hat{r} = (0.707)\hat{i} - (0.707)\hat{j}$$



Substitute and simplify to obtain:

$$\vec{E}_{\text{line}} = \frac{2\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(4.00\ \mu\text{C/m}\right)}{0.707\ \text{m}}\left[(0.707)\hat{\boldsymbol{i}} - (0.707)\hat{\boldsymbol{j}}\right]$$
$$= (101.7\ \text{kN/C})\left[(0.707)\hat{\boldsymbol{i}} - (0.707)\hat{\boldsymbol{j}}\right] = (71.90\ \text{kN/C})\hat{\boldsymbol{i}} + (-71.90\ \text{kN/C})\hat{\boldsymbol{j}}$$

Letting r' represent the distance from the center of the sphere to P, apply Gauss's law to a spherical surface of radius r' centered at (1 m, 0) to obtain an expression for $\vec{E}_{\text{sphere}}$ at P:

$$\vec{E}_{\text{sphere}} = \frac{4\pi}{3}kr'\rho\hat{\boldsymbol{r}}'$$

where $\hat{\boldsymbol{r}}'$ is directed toward the center of the sphere.

Refer to the diagram used above to obtain:

$$\vec{\boldsymbol{r}}' = -(0.50\ \text{m})\hat{\boldsymbol{i}} - (0.50\ \text{m})\hat{\boldsymbol{j}}$$

and

$$\hat{\boldsymbol{r}}' = -(0.707)\hat{\boldsymbol{i}} - (0.707)\hat{\boldsymbol{j}}$$

Substitute numerical values and simplify to obtain:

$$\vec{E}_{\text{sphere}} = \frac{4\pi}{3}\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(0.707\ \text{m})\left(-6.00\ \mu\text{C/m}^3\right)\left[(0.707)\hat{\boldsymbol{i}} + (0.707)\hat{\boldsymbol{j}}\right]$$
$$= (-112.9\ \text{kN/C})\left(\hat{\boldsymbol{i}} + \hat{\boldsymbol{j}}\right) = (-112.9\ \text{kN/C})\hat{\boldsymbol{i}} + (-112.9\ \text{kN/C})\hat{\boldsymbol{j}}$$

Substitute for $\vec{E}_{\text{plane}}$, $\vec{E}_{\text{line}}$, and $\vec{E}_{\text{sphere}}$ and simplify to obtain:

$$\vec{E} = (-112.9\ \text{kN/C})\hat{\boldsymbol{i}} + (71.90\ \text{kN/C})\hat{\boldsymbol{i}} + (-71.90\ \text{kN/C})\hat{\boldsymbol{j}} + (-112.9\ \text{kN/C})\hat{\boldsymbol{i}}$$
$$+ (-112.9\ \text{kN/C})\hat{\boldsymbol{j}}$$
$$= (-154.0\ \text{kN/C})\hat{\boldsymbol{i}} + (-184.9\ \text{kN/C})\hat{\boldsymbol{j}}$$

Finally, find the magnitude and direction of $\vec{E}$:

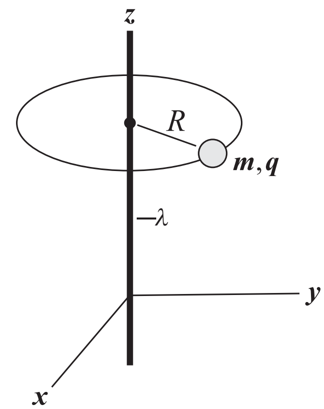
$$E = \sqrt{(-154.0\ \text{kN/C})^2 + (-184.9\ \text{kN/C})^2} = \boxed{241\ \text{kN/C}}$$

and

$$\theta = \tan^{-1}\left(\frac{-154.0\ \text{kN/C}}{-184.9\ \text{kN/C}}\right) = \boxed{220°}$$

79 •• [SSM] A uniformly charged, infinitely long line of negative charge has a linear charge density of $-\lambda$ and is located on the z axis. A small positively charged particle that has a mass m and a charge q is in a circular orbit of radius R in the xy plane centered on the line of charge. (a) Derive an expression for the speed of the particle. (b) Obtain an expression for the period of the particle's orbit.

Picture the Problem (a) We can apply Newton's second law to the particle to express its speed as a function of its mass m, charge q, and the radius of its path R, and the strength of the electric field due to the infinite line charge E. (b) The period of the particle's motion is the ratio of the circumference of the circle in which it travels divided by its orbital speed.



(a) Apply Newton's second law to the particle to obtain:

$$\sum F_{\text{radial}} = qE = m\frac{v^2}{R}$$

where the inward direction is positive.

Solving for v yields:

$$v = \sqrt{\frac{qRE}{m}}$$

The strength of the electric field at a distance R from the infinite line charge is given by:

$$E = \frac{2k\lambda}{R}$$

Substitute for E and simplify to obtain:

$$v = \boxed{\sqrt{\frac{2kq\lambda}{m}}}$$

(b) The speed of the particle is equal to the circumference of its orbit divided by its period:

$$v = \frac{2\pi R}{T} \Rightarrow T = \frac{2\pi R}{v}$$

Substitute for v and simplify to obtain:

$$T = \boxed{\pi R\sqrt{\frac{2m}{kq\lambda}}}$$

80 •• A stationary ring of radius a that lies in the yz plane has a uniformly distributed positive charge Q. A small particle that has mass m and a negative charge q is located at the center of the ring. (a) Show that if $x << a$, the electric field along the axis of the ring is proportional to x. (b) Find the force on the particle of mass m as a function of x. (c) Show that if the particle is given a small displacement in the $+x$ direction, it will perform simple harmonic motion. (d) What is the frequency of that motion?

Picture the Problem Starting with the equation for the electric field on the axis of ring charge, we can factor the denominator of the expression to show that, for $x << a$, E_x is proportional to x. We can use $F_x = qE_x$ to express the force acting on the particle and apply Newton's second law to show that, for small displacements from equilibrium, the particle will execute simple harmonic motion. Finally, we can find the period of the motion from its angular frequency, which we can obtain from the differential equation of motion.

(a) Express the electric field on the axis of the ring of charge:

$$E_x = \frac{kQx}{\left(x^2 + a^2\right)^{3/2}}$$

Factor a^2 from the denominator of E_x to obtain:

$$E_x = \frac{kQx}{\left[a^2\left(1 + \frac{x^2}{a^2}\right)\right]^{3/2}} = \frac{kQx}{a^3\left(1 + \frac{x^2}{a^2}\right)^{3/2}} \approx \boxed{\frac{kQ}{a^3}x}$$

provided $x << a$.

(b) Express the force acting on the particle as a function of its charge and the electric field:

$$F_x = qE_x = \boxed{\frac{kqQ}{a^3}x}$$

(c) Because the negatively charged particle experiences a linear restoring force, we know that its motion will be simple harmonic. Apply Newton's second law to the negatively charged particle to obtain:

$$m\frac{d^2x}{dt^2} = -\frac{kqQ}{a^3}x$$

or

$$\boxed{\frac{d^2x}{dt^2} + \frac{kqQ}{ma^3}x = 0}$$

the differential equation of simple harmonic motion.

(*d*) Relate the frequency of the simple harmonic motion to its angular frequency:

$$f = \frac{\omega}{2\pi} \qquad (1)$$

From the differential equation we have:

$$\omega^2 = \frac{kqQ}{ma^3} \Rightarrow \omega = \sqrt{\frac{kqQ}{ma^3}}$$

Substitute for ω in equation (1) and simplify to obtain:

$$f = \boxed{\frac{1}{2\pi}\sqrt{\frac{kqQ}{ma^3}}}$$

81 •• [SSM] The charges Q and q of Problem 80 are +5.00 μC and –5.00 μC, respectively, and the radius of the ring is 8.00 cm. When the particle is given a small displacement in the x direction, it oscillates about its equilibrium position at a frequency of 3.34 Hz. (*a*) What is the particle's mass? (*b*) What is the frequency if the radius of the ring is doubled to 16.0 cm and all other parameters remain unchanged?

Picture the Problem Starting with the equation for the electric field on the axis of a ring charge, we can factor the denominator of the expression to show that, for $x << a$, E_x is proportional to x. We can use $F_x = qE_x$ to express the force acting on the particle and apply Newton's second law to show that, for small displacements from equilibrium, the particle will execute simple harmonic motion. Finally, we can find the angular frequency of the motion from the differential equation and use this expression to find the frequency of the motion when the radius of the ring is doubled and all other parameters remain unchanged.

(*a*) Express the electric field on the axis of the ring of charge:

$$E_x = \frac{kQx}{\left(x^2 + a^2\right)^{3/2}}$$

Factor a^2 from the denominator of E_x to obtain:

$$E_x = \frac{kQx}{\left[a^2\left(1+\frac{x^2}{a^2}\right)\right]^{3/2}} = \frac{kQx}{a^3\left(1+\frac{x^2}{a^2}\right)^{3/2}} \approx \frac{kQ}{a^3}x$$

provided $x << a$.

Express the force acting on the particle as a function of its charge and the electric field:

$$F_x = qE_x = \frac{kqQ}{a^3}x$$

Because the negatively charged particle experiences a linear restoring force, we know that its motion will be simple harmonic. Apply Newton's second law to the negatively charged particle to obtain:

$$m\frac{d^2x}{dt^2}=-\frac{kqQ}{a^3}x$$

or

$$\frac{d^2x}{dt^2}+\frac{kqQ}{ma^3}x=0$$

the differential equation of simple harmonic motion.

The angular frequency of the simple harmonic motion of the particle is given by:

$$\omega=\sqrt{\frac{kqQ}{ma^3}} \quad (1)$$

Solving for m yields:

$$m=\frac{kqQ}{\omega^2a^3}=\frac{kqQ}{4\pi^2f^2a^3}$$

Substitute numerical values and evaluate m:

$$m=\frac{\left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left|\left(-5.00\,\mu\text{C}\right)\right|\left(5.00\,\mu\text{C}\right)}{4\pi^2\left(3.34\,\text{s}^{-1}\right)^2\left(8.00\,\text{cm}\right)^3}=\boxed{0.997\,\text{kg}}$$

(*b*) Express the angular frequency of the motion if the radius of the ring is doubled:

$$\omega'=\sqrt{\frac{kqQ}{m(2a)^3}} \quad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{\omega'}{\omega}=\frac{2\pi f'}{2\pi f}=\frac{\sqrt{\frac{kqQ}{m(2a)^3}}}{\sqrt{\frac{kqQ}{ma^3}}}=\frac{1}{\sqrt{8}}$$

Solve for f' to obtain:

$$f'=\frac{f}{\sqrt{8}}=\frac{3.34\,\text{Hz}}{\sqrt{8}}=\boxed{1.18\,\text{Hz}}$$

82 •• If the radius of the ring in Problem 80 is doubled while keeping the linear charge density on the ring the same, does the frequency of oscillation of the particle change? If so, by what factor does it change?

Picture the Problem Starting with the equation for the electric field on the axis of a ring charge, we can factor the denominator of the expression to show that, for $x \ll a$, E_x is proportional to x. We can use $F_x = qE_x$ to express the force acting on the particle and apply Newton's second law to show that, for small displacements from equilibrium, the particle will execute simple harmonic motion. Finally, we can find the angular frequency of the motion from the differential equation and use this expression to find its value when the radius of the ring is doubled while keeping the linear charge density on the ring constant.

Express the electric field on the axis of the ring of charge:

$$E_x = \frac{kQx}{\left(x^2 + a^2\right)^{3/2}}$$

Factor a^2 from the denominator of E_x to obtain:

$$E_x = \frac{kQx}{\left[a^2\left(1 + \frac{x^2}{a^2}\right)\right]^{3/2}} = \frac{kQx}{a^3\left(1 + \frac{x^2}{a^2}\right)^{3/2}} \approx \frac{kQ}{a^3}x$$

provided $x \ll a$.

Express the force acting on the particle as a function of its charge and the electric field:

$$F_x = qE_x = \frac{kqQ}{a^3}x$$

Because the negatively charged particle experiences a linear restoring force, we know that its motion will be simple harmonic. Apply Newton's second law to the negatively charged particle to obtain:

$$m\frac{d^2x}{dt^2} = -\frac{kqQ}{a^3}x$$

or

$$\frac{d^2x}{dt^2} + \frac{kqQ}{ma^3}x = 0,$$

the differential equation of simple harmonic motion.

The angular frequency of the simple harmonic motion of the particle is given by:

$$\omega = \sqrt{\frac{kqQ}{ma^3}} \qquad (1)$$

Express the angular frequency of the motion if the radius of the ring is doubled while keeping the linear charge density constant (that is, doubling Q):

$$\omega' = \sqrt{\frac{kq(2Q)}{m(2a)^3}} \qquad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{\omega'}{\omega} = \frac{2\pi f'}{2\pi f} = \frac{\sqrt{\dfrac{kq(2Q)}{m(2a)^3}}}{\sqrt{\dfrac{kqQ}{ma^3}}} = \frac{1}{2}$$

Yes. The frequency changes by a factor of 0.5.

83 ••• A uniformly charged non-conducting solid sphere of radius R has its center at the origin and has volume charge density of ρ. (a) Show that at a point within the sphere a distance r from the center $\vec{E} = \dfrac{\rho}{3\in_0} r\hat{\mathbf{r}}$. ($b$) Material is removed from the sphere leaving a spherical cavity of radius $b = R/2$ with its center at $x = b$ on the x axis (Figure 22-46). Calculate the electric field at points 1 and 2 shown in Figure 22-46. *Hint: Model the sphere-with-cavity as two uniform spheres of equal positive and negative charge densities.*

Picture the Problem In Part (a), you can apply Gauss's law to express $\vec{E}$ as a function of r for the uniformly charged nonconducting sphere with its center at the origin. In Part (b), you can use the hint to express the field at a generic point $P(x,y)$ in the cavity as the sum of the fields due to equal positive and negative charge densities and then evaluate this expression at points 1 and 2.

(a) The electric field at a distance r from the center of the uniformly charged nonconducting sphere is given by:

$$\vec{E}_\rho = E\hat{\mathbf{r}} \qquad (1)$$

where $\hat{\mathbf{r}}$ is a unit vector pointing radially outward.

Apply Gauss's law to a spherical surface of radius r centered at the origin to obtain:

$$\oint_S E_n dA = E_\rho\left(4\pi r^2\right) = \frac{Q_{\text{inside}}}{\in_0}$$

Relate Q_{inside} to the charge density ρ:

$$\rho = \frac{Q_{\text{inside}}}{\frac{4}{3}\pi r^3} \Rightarrow Q_{\text{inside}} = \tfrac{4}{3}\rho\pi r^3$$

Substitute for Q_{inside}:

$$E_\rho\left(4\pi r^2\right) = \frac{4\rho\pi r^3}{3\in_0}$$

Solve for E_ρ to obtain:

$$E_\rho = \frac{\rho r}{3\in_0}$$

Substitute for E in equation (1) to obtain:

$$\vec{E}_\rho = \boxed{\frac{\rho}{3\in_0} r\hat{r}}$$

(*b*) The electric field at point $P(x,y)$ is the sum of the electric fields due to the two charge distributions:

$$\vec{E} = \vec{E}_\rho + \vec{E}_{-\rho} = E_\rho \hat{r} + E_{-\rho}\hat{r}' \quad (2)$$

where $\hat{r}'$ is a unit vector normal to a spherical Gaussian surface whose center is at $x = b$.

Apply Gauss's law to a spherical surface of radius r' centered at $x = b = R/2$ to obtain:

$$\oint_S E_n dA = E_{-\rho}\left(4\pi r'^2\right) = \frac{Q_{\text{inside}}}{\in_0}$$

Relate Q_{inside} to the charge density $-\rho$:

$$-\rho = \frac{Q_{\text{inside}}}{\frac{4}{3}\pi r'^3} \Rightarrow Q_{\text{inside}} = -\tfrac{4}{3}\rho\pi r'^3$$

Substitute for Q_{inside} to obtain:

$$E_{-\rho}\left(4\pi r'^2\right) = -\frac{4\pi r'^3\rho}{3\in_0}$$

Solving for $E_{-\rho}$ yields:

$$E_{-\rho} = -\frac{\rho}{3\in_0} r'$$

Substitute for E_ρ and $E_{-\rho}$ in equation (2) to obtain:

$$\vec{E} = \frac{\rho}{3\in_0} r\hat{r} - \frac{\rho}{3\in_0} r'\hat{r} \qquad (3)$$

The vectors $\vec{r} = r\hat{r}$ and $\vec{r}' = r'\hat{r}'$ are given by:

$$\vec{r} = x\hat{i} + y\hat{j} \text{ and } \vec{r}' = (x-b)\hat{i} + y\hat{j}$$

where x and y are the coordinates of any point in the cavity.

Substitute for $r\hat{r}$ and $r'\hat{r}'$ in equation (3) and simplify to obtain:

$$\vec{E} = \frac{\rho}{3\in_0}\left(x\hat{i} + y\hat{j}\right) - \frac{\rho}{3\in_0}\left[(x-b)\hat{i} + y\hat{j}\right] = \frac{\rho b}{3\in_0}\hat{i}$$

Because $\vec{E}$ is independent of x and y:

$$\vec{E}_1 = \vec{E}_2 = \boxed{\frac{\rho b}{3\in_0}\hat{i}}$$

84 ••• Show that the electric field throughout the cavity of Problem 83*b* is uniform and is given by $\vec{E} = \frac{\rho}{3\in_0} b\hat{i}$.

Picture the Problem The electric field in the cavity is the sum of the electric field due to the uniform and positive charge distribution of the sphere whose radius is a and the electric field due to any charge in the spherical cavity whose radius is b. You can use the hint given in Problem 83 to express the field at a generic point $P(x,y)$ in the cavity as the sum of the fields due to equal positive and negative charge densities to show that $\vec{E} = \frac{\rho}{3\in_0} b\hat{i}$.

The electric field at point $P(x,y)$ is the sum of the electric fields due to the two charge distributions:

$$\vec{E} = \vec{E}_\rho + \vec{E}_{-\rho} = E_\rho \hat{r} + E_{-\rho}\hat{r}' \qquad (1)$$

where $\hat{r}'$ is a unit vector normal to a spherical Gaussian surface whose center is at $x = b$.

Apply Gauss's law to a spherical surface of radius r' centered at $x = b = R/2$ to obtain:

$$\oint_S E_n dA = E_{-\rho}\left(4\pi r'^2\right) = \frac{Q_{\text{inside}}}{\in_0}$$

Relate Q_{inside} to the charge density $-\rho$:

$$-\rho = \frac{Q_{\text{inside}}}{\frac{4}{3}\pi r'^3} \Rightarrow Q_{\text{inside}} = -\tfrac{4}{3}\rho\pi r'^3$$

Substitute for Q_{inside} to obtain:

$$E_{-\rho}\left(4\pi r'^2\right) = -\frac{4\pi r'^3 \rho}{3\in_0}$$

Solving for $E_{-\rho}$ yields:

$$E_{-\rho} = -\frac{\rho}{3\in_0} r'$$

From Problem 83:

$$E_\rho = \frac{\rho}{3\in_0} r$$

Substitute for E_ρ and $E_{-\rho}$ in equation (1) to obtain:

$$\vec{E} = \frac{\rho}{3\in_0} r\hat{r} - \frac{\rho}{3\in_0} r'\hat{r} \qquad (2)$$

The vectors $\vec{r} = r\hat{r}$ and $\vec{r}' = r'\hat{r}'$ are given by:

$\vec{r} = x\hat{i} + y\hat{j}$ and $\vec{r}' = (x-b)\hat{i} + y\hat{j}$

where x and y are the coordinates of any point in the cavity.

Substitute for $r\hat{r}$ and $r'\hat{r}'$ in equation (2) and simplify to obtain:

$$\vec{E} = \frac{\rho}{3\in_0}\left(x\hat{i} + y\hat{j}\right) - \frac{\rho}{3\in_0}\left[(x-b)\hat{i} + y\hat{j}\right] = \boxed{\frac{\rho}{3\in_0} b\hat{i}}$$

85 ••• The cavity in Problem 83*b* is now filled with a uniformly charged non-conducting material with a total charge of Q. Calculate the new values of the electric field at points 1 and 2 shown in Figure 22-46.

Picture the Problem The electric field at a generic point $P(x,y)$ in the cavity is the sum of the fields due to the positive charge density and the total charge Q.

The electric field at point $P(x,y)$ is the sum of the electric fields due to the two charge distributions:

$$\vec{E} = \vec{E}_\rho + \vec{E}_{-\rho} + \vec{E}_Q \qquad (1)$$

where $\hat{r}'$ is a unit vector normal to a spherical Gaussian surface whose center is at $x = b$.

From Problem 83:

$$\vec{E}_\rho + \vec{E}_{-\rho} = \frac{\rho b}{3\epsilon_0}\hat{i}$$

Substituting in equation (1) yields:

$$\vec{E} = \frac{\rho b}{3\epsilon_0}\hat{i} + \vec{E}_Q$$

Assuming that the cavity is filled with positive charge Q:

$$\vec{E} = \frac{\rho b}{3\epsilon_0}\hat{i} + \frac{Q}{4\pi\epsilon_0 b^3}r'\hat{r}$$

The vectors $\vec{r} = r\hat{r}$ and $\vec{r}' = r'\hat{r}'$ are given by:

$$\vec{r} = x\hat{i} + y\hat{j} \text{ and } \vec{r}' = (x-b)\hat{i} + y\hat{j}$$

where x and y are the coordinates of any point in the cavity.

Substitute for $r\hat{r}$ and $r'\hat{r}'$ and simplify to obtain:

$$\vec{E} = \frac{\rho b}{3\epsilon_0}\hat{i} + \frac{Q}{4\pi\epsilon_0 b^3}\left[(x-b)\hat{i} + y\hat{j}\right]$$

At point 1, $x = 2b$ and $y = 0$:

$$\vec{E}(2b,0) = \frac{\rho b}{3\epsilon_0}\hat{i} - \frac{Q}{4\pi\epsilon_0 b^3}\left[(2b-b)\hat{i}\right] = \boxed{\left(\frac{\rho b}{3\epsilon_0} + \frac{Q}{4\pi\epsilon_0 b^2}\right)\hat{i}}$$

At point 2, $x = 0$ and $y = 0$:

$$\vec{E}(0,0) = \frac{\rho b}{3\epsilon_0}\hat{i} + \frac{Q}{4\pi\epsilon_0 b^3}\left[(-b)\hat{i}\right] = \boxed{\left(\frac{\rho b}{3\epsilon_0} - \frac{Q}{4\pi\epsilon_0 b^2}\right)\hat{i}}$$

86 ••• A *small* Gaussian surface in the shape of a cube has faces parallel to the *xy*, *xz*, and *yz* planes (Figure 22-47) and is in a region in which the electric field is parallel to the *x* axis. (*a*) Using the differential approximation, show that the net electric flux of the electric field out of the Gaussian surface is given by $\phi_{\text{net}} \approx \frac{\partial E_x}{\partial x}\Delta V$, where ΔV is the volume enclosed by the Gaussian surface.

(*b*) Using Gauss's law and the results of Part (*a*) show that $\frac{\partial E_x}{\partial x} = \frac{\rho}{\epsilon_0}$, where ρ is the volume charge density inside the cube. (This equation is the one-dimensional version of the point form of Gauss's law.)

Picture the Problem Let the coordinates of one corner of the cube be (*x,y,z*), and assume that the sides of the cube are Δx, Δy, and Δz and compute the flux through the faces of the cube that are parallel to the *yz* plane. The net flux of the electric field out of the gaussian surface is the difference between the flux out of the surface and the flux into the surface.

(*a*) The net flux out of the cube is given by:

$$\phi_{\text{net}} = \phi(x+\Delta x) - \phi(x)$$

Use a Taylor series expansion to express the net flux through faces of the cube that are parallel to the *yz* plane:

$$\phi_{\text{net}} = \phi(x) + (\Delta x)\phi'(x) + \tfrac{1}{2}(\Delta x)^2\phi''(x) + \ldots - \phi(x) = (\Delta x)\phi'(x) + \tfrac{1}{2}(\Delta x)^2\phi''(x) + \ldots$$

Neglecting terms higher than first order we have:

$$\phi_{\text{net}} \approx \Delta x\phi'(x)$$

Because the electric field is in the *x* direction, $\phi(x)$ is:

$$\phi(x) = E_x\Delta y\Delta z$$

and

$$\phi'(x) = \frac{\partial E_x}{\partial x}\Delta y\Delta z$$

Substitute for $\phi'(x)$ to obtain:

$$\phi_{\text{net}} \approx \Delta x\frac{\partial E_x}{\partial x}(\Delta y\Delta z) = \frac{\partial E_x}{\partial x}(\Delta x\Delta y\Delta z) = \boxed{\frac{\partial E_x}{\partial x}\Delta V}$$

(*b*) From Gauss's law, the net flux through any surface is:

$$\phi_{\text{net}} = \frac{q_{\text{encl}}}{\epsilon_0} = \frac{\rho}{\epsilon_0}\Delta V$$

From Part (*a*):

$$\phi_{\text{net}} = \frac{\partial E_x}{\partial x}\Delta V$$

Equate these two expressions and simplify to obtain:

$$\frac{\partial E_x}{\partial x}\Delta V = \frac{\rho}{\epsilon_0}\Delta V \Rightarrow \frac{\partial E_x}{\partial x} = \boxed{\frac{\rho}{\epsilon_0}}$$

87 ••• [SSM] Consider a simple but surprisingly accurate model for the hydrogen molecule: two positive point charges, each having charge +*e*, are placed inside a uniformly charged sphere of radius *R*, which has a charge equal to –2*e*. The two point charges are placed symmetrically, equidistant from the center of the sphere (Figure 22-48). Find the distance from the center, *a*, where the net force on either point charge is zero.

Picture the Problem We can find the distance from the center where the net force on either charge is zero by setting the sum of the forces acting on either point charge equal to zero. Each point charge experiences two forces; one a Coulomb force of repulsion due to the other point charge, and the second due to that fraction of the sphere's charge that is between the point charge and the center of the sphere that creates an electric field at the location of the point charge.

Apply $\sum F = 0$ to either of the point charges:

$$F_{\text{Coulomb}} - F_{\text{field}} = 0 \qquad (1)$$

Express the Coulomb force on the proton:

$$F_{\text{Coulomb}} = \frac{ke^2}{(2a)^2} = \frac{ke^2}{4a^2}$$

The force exerted by the field *E* is:

$$F_{\text{field}} = eE$$

Apply Gauss's law to a spherical surface of radius *a* centered at the origin:

$$E\left(4\pi\, a^2\right) = \frac{Q_{\text{enclosed}}}{\epsilon_0}$$

Relate the charge density of the electron sphere to Q_{enclosed}:

$$\frac{2e}{\frac{4}{3}\pi R^3} = \frac{Q_{\text{enclosed}}}{\frac{4}{3}\pi a^3} \Rightarrow Q_{\text{enclosed}} = \frac{2ea^3}{R^3}$$

Substitute for Q_{enclosed}:

$$E\left(4\pi a^2\right) = \frac{2ea^3}{\epsilon_0\, R^3}$$

Solve for *E* to obtain:

$$E = \frac{ea}{2\pi\,\epsilon_0\, R^3} \Rightarrow F_{\text{field}} = \frac{e^2 a}{2\pi\,\epsilon_0\, R^3}$$

Substitute for F_{Coulomb} and F_{field} in equation (1):

$$\frac{ke^2}{4a^2}-\frac{e^2a}{2\pi\in_0 R^3}=0$$

or

$$\frac{ke^2}{4a^2}-\frac{2ke^2a}{R^3}=0\Rightarrow a=\sqrt[3]{\frac{1}{8}}R=\boxed{\tfrac{1}{2}R}$$

88 ••• An electric dipole that has a dipole moment of $\vec{\boldsymbol{p}}$ is located at a perpendicular distance R from an infinitely long line charge that has a uniform linear charge density λ. Assume that the dipole moment is in the same direction as the field of the line of charge. Determine an expression for the electric force on the dipole.

Picture the Problem We can find the field due to the infinitely long line charge from $E=2k\lambda/r$ and the force that acts on the dipole using $F=p\,dE/dr$.

Express the force acting on the dipole:

$$F=p\frac{dE}{dr} \qquad (1)$$

The electric field at the location of the dipole is given by:

$$E=\frac{2k\lambda}{r}$$

Substitute for E in equation (1) to obtain:

$$F=p\frac{d}{dr}\left[\frac{2k\lambda}{r}\right]=\boxed{-\frac{2k\lambda p}{r^2}}$$

where the minus sign indicates that the dipole is attracted to the line charge.

Chapter 23
Electrical Potential

Conceptual Problems

1 • [SSM] A proton is moved to the left in a uniform electric field that points to the right. Is the proton moving in the direction of increasing or decreasing electric potential? Is the electrostatic potential energy of the proton increasing or decreasing?

Determine the Concept The proton is moving to a region of higher potential. The proton's electrostatic potential energy is increasing.

2 • An electron is moved to the left in a uniform electric field that points to the right. Is the electron moving in the direction of increasing or decreasing electric potential? Is the electrostatic potential energy of the electron increasing or decreasing?

Determine the Concept The electron is moving to a region of higher electric potential. The electron's electrostatic potential energy is decreasing.

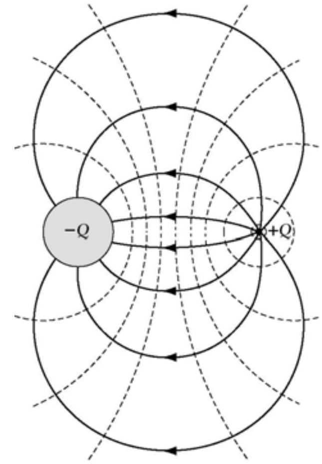
3 • If the electric potential is uniform throughout a region of space, what can be said about the electric field in that region?

Determine the Concept If V is constant, its gradient is zero; consequently the electric field is zero throughout the region.

4 • If V is known at only a single point in space, can $\vec{E}$ be found at that point? Explain your answer.

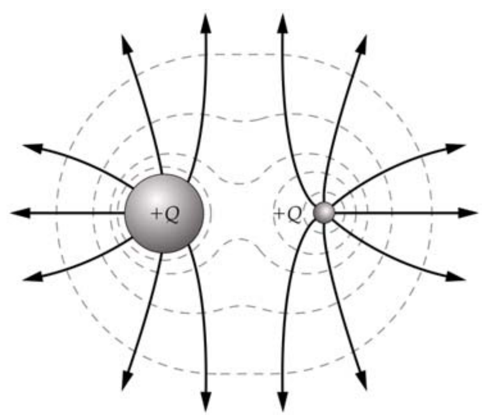
Determine the Concept No. $\vec{E}$ cannot be determined without knowing V at a continuum of points.

5 •• [SSM] Figure 23-29 shows a point particle that has a positive charge $+Q$ and a metal sphere that has a charge $-Q$. Sketch the electric field lines and equipotential surfaces for this system of charges.



Picture the Problem The electric field lines, shown as solid lines, and the equipotential surfaces (intersecting the plane of the paper), shown as dashed lines, are sketched in the adjacent figure. The point charge $+Q$ is the point at the right, and the metal sphere with charge $-Q$ is at the left. Near the two charges the equipotential surfaces are spheres, and the field lines are normal to the metal sphere at the sphere's surface.

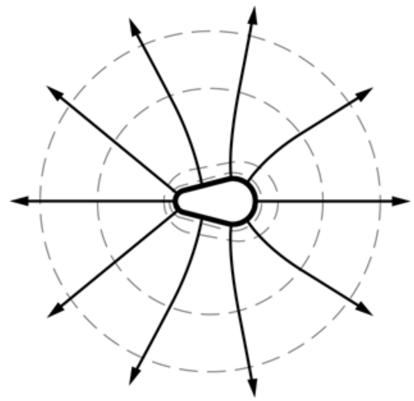
6 •• Figure 23-30 shows a point particle that has a negative charge $-Q$ and a metal sphere that has a charge $+Q$. Sketch the electric field lines and equipotential surfaces for this system of charges.



Picture the Problem The electric field lines, shown as solid lines, and the equipotential surfaces (intersecting the plane of the paper), shown as dashed lines, are sketched in the adjacent figure. The point charge $+Q$ is the point at the right, and the metal sphere with charge $+Q$ is at the left. Near the two charges the equipotential surfaces are spheres, and the field lines are normal to the metal sphere at the sphere's surface. Very far from both charges, the equipotential surfaces and field lines approach those of a point charge $2Q$ located at the midpoint.

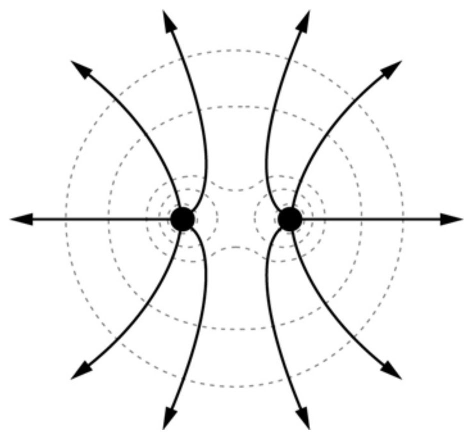
7 •• Sketch the electric field lines and equipotential surfaces for the region surrounding the charged conductor shown in Figure 23-31, assuming that the conductor has a net positive charge.

Picture the Problem The equipotential surfaces are shown with dashed lines, the field lines are shown in solid lines. It is assumed that the conductor carries a positive charge. Near the conductor the equipotential surfaces follow the conductor's contours; far from the conductor, the equipotential surfaces are spheres centered on the conductor. The electric field lines are perpendicular to the equipotential surfaces.



8 •• Two equal positive point charges are separated by a finite distance. Sketch the electric field lines and the equipotential surfaces for this system.

Picture the Problem The equipotential surfaces are shown with dashed lines, the electric field lines are shown with solid lines. Near each charge, the equipotential surfaces are spheres centered on each charge; far from the charges, the equipotential surface is a sphere centered at the midpoint between the charges. The electric field lines are perpendicular to the equipotential surfaces.



9 •• Two point charges are fixed on the x-axis. (a) Each has a positive charge q. One is at $x = -a$ and the other is at $x = +a$. At the origin, which of the following is true?

(1) $\vec{E} = 0$ and $V = 0$,
(2) $\vec{E} = 0$ and $V = 2kq/a$,
(3) $\vec{E} = \left(2kq/a^2\right)\hat{i}$ and $V = 0$,
(4) $\vec{E} = \left(2kq/a^2\right)\hat{i}$ and $V = 2kq/a$,
(5) None of the above.

(b) One has a positive charge $+q$ and the other has a negative charge $-q$. The positive point charge is at $x = -a$ and the negative point charge is at $x = +a$. At the origin, which of the following is true?

(1) $\vec{E} = 0$ and $V = 0$,

(2) $\vec{E} = 0$ and $V = 2kq/a$,
(3) $\vec{E} = \left(2kq/a^2\right)\hat{i}$ and $V = 0$,
(4) $\vec{E} = \left(2kq/a^2\right)\hat{i}$ and $V = 2kq/a$,
(5) None of the above.

Picture the Problem We can use Coulomb's law and the superposition of fields to find $\vec{E}$ at the origin and the definition of the electric potential due to a point charge to find V at the origin.

(*a*) Apply Coulomb's law and the superposition of fields to find the electric field $\vec{E}$ at the origin:

$$\vec{E} = \vec{E}_{+q\text{ at }-a} + \vec{E}_{+q\text{ at }+a} = \frac{kq}{a^2}\hat{i} - \frac{kq}{a^2}\hat{i} = 0$$

The potential V at the origin is given by:

$$V = V_{+q\text{ at }-a} + V_{+q\text{ at }+a} = \frac{kq}{a} + \frac{kq}{a} = \frac{2kq}{a}$$

and $\boxed{(2)}$ is correct.

(*b*) Apply Coulomb's law and the superposition of fields to find the electric field $\vec{E}$ at the origin:

$$\vec{E} = \vec{E}_{+q\text{ at }-a} + \vec{E}_{-q\text{ at }+a} = \left(\frac{kq}{a^2}\right)\hat{i} + \left(\frac{kq}{a^2}\right)\hat{i} = \left(\frac{2kq}{a^2}\right)\hat{i}$$

The potential V at the origin is given by:

$$V = V_{+q\text{ at }-a} + V_{-q\text{ at }+a} = \frac{kq}{a} + \frac{k(-q)}{a} = 0$$

and $\boxed{(3)}$ is correct.

10 •• The electrostatic potential (in volts) is given by $V(x, y, z) = 4.00|x| + V_0$, where V_0 is a constant, and x is in meters. (*a*) Sketch the electric field for this potential. (*b*) Which of the following charge distributions is most likely responsible for this potential: (1) A negatively charged flat sheet in the $z = 0$ plane, (2) a point charge at the origin, (3) a positively charged flat sheet in the $x = 0$ plane, or (4) a uniformly charged sphere centered at the origin. Explain your answer.

Picture the Problem We can use $\vec{E} = -\frac{\partial V}{\partial x}\hat{i}$ to find the electric field corresponding to the given potential and then compare its form to those produced by the four alternatives listed.

(*a*) Find the electric field corresponding to this potential function:

$$\vec{E} = -\frac{\partial V}{\partial x}\hat{i} = -\frac{\partial}{\partial x}\left[4.00|x| + V_0\right]\hat{i}$$
$$= -4.00\frac{\partial}{\partial x}\left[|x|\right]\hat{i}$$

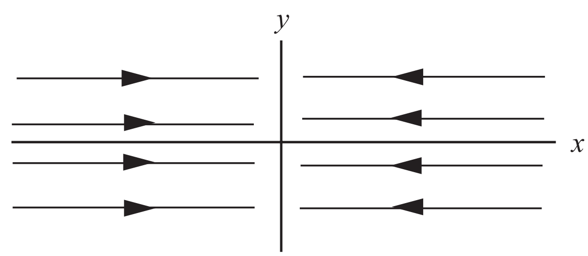
If $x > 0$, then $\frac{\partial}{\partial x}\left[|x|\right] = 1$ and:

$$\vec{E}_{x>0} = \left(-4.00\frac{\text{V}}{\text{m}}\right)\hat{i}$$

If $x < 0$, then $\frac{\partial}{\partial x}\left[|x|\right] = -1$ and:

$$\vec{E}_{x<0} = \left(4.00\frac{\text{V}}{\text{m}}\right)\hat{i}$$

A sketch of the electric field in this region follows:



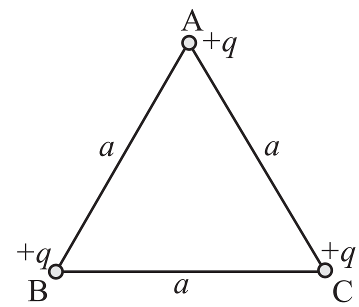
(*b*) $\boxed{(1)}$ is correct because field lines end on negative charges.

11 •• **[SSM]** The electric potential is the same everywhere on the surface of a conductor. Does this mean that the surface charge density is also the same everywhere on the surface? Explain your answer.

Determine the Concept No. The local surface charge density is proportional to the normal component of the electric field, not the potential on the surface.

12 •• Three identical positive point charges are located at the vertices of an equilateral triangle. If the length of each side of the triangle shrinks to one-fourth of its original length, by what factor does the electrostatic potential energy of this system change? (The electrostatic potential energy approaches zero if the length of each side of the triangle approaches infinity.)

Picture the Problem Points A, B, and C are at the vertices of an equilateral triangle of side a. The electrostatic potential energy of the system of the three equal positive point charges is the total work that must be done on the charges to bring them from infinity to this configuration.



The electrostatic potential energy is the work required to assemble the three charges at the vertices of the equilateral triangle:

$$U = W_{\infty \to \mathrm{A}} + W_{\infty \to \mathrm{B}} + W_{\infty \to \mathrm{C}} \qquad (1)$$

Place the first charge at point A. To accomplish this step, the work $W_{\infty \to \mathrm{A}}$ that is needed is zero:

$$W_{\infty \to \mathrm{A}} = 0$$

Bring the second charge to point B. The work required is $W_{\infty \to \mathrm{B}} = qV_{\mathrm{A}}$, where V_{A} is the potential at point B due to the first charge at point A a distance a away:

$$W_{\infty \to \mathrm{B}} = qV_{\mathrm{A}} = q\left(\frac{kq}{a}\right) = \frac{kq^2}{a}$$

Similarly, $W_{\infty \to \mathrm{C}}$ is given by:

$$W_{\infty \to \mathrm{C}} = qV_{\mathrm{C}} = q\left(\frac{kq}{a} + \frac{kq}{a}\right) = \frac{2kq^2}{a}$$

Substituting for $W_{\infty \to \mathrm{A}}$, $W_{\infty \to \mathrm{B}}$, and $W_{\infty \to \mathrm{C}}$ in equation (1) yields:

$$U = 0 + \frac{kq^2}{a} + \frac{2kq^2}{a} = \frac{3kq^2}{a}$$

If the length of each side of the triangle shrinks to one-fourth of its original length, its electrostatic potential energy U' becomes:

$$U' = \frac{3kq^2}{\frac{1}{4}a} = 4\left(\frac{3kq^2}{a}\right) = 4U$$

Hence the electrostatic potential energy of this system increases by a factor of $\boxed{4}$.

Estimation and Approximation Problems

13 • [SSM] Estimate maximum the potential difference between a thundercloud and Earth, given that the electrical breakdown of air occurs at fields of roughly 3.0×10^6 V/m.

Picture the Problem The potential difference between the thundercloud and Earth is the product of the electric field between them and their separation.

Express the potential difference between the cloud and Earth as a function of their separation d and electric field E between them:

$$V = Ed$$

Assuming that the thundercloud is at a distance of about 1 km above the surface of Earth, the potential difference is approximately:

$$V = \left(3.0\times10^{6}\ \text{V/m}\right)\left(10^{3}\ \text{m}\right) = \boxed{3.0\times10^{9}\ \text{V}}$$

Note that this is an upper bound, as there will be localized charge distributions on the thundercloud which raise the local electric field above the average value.

14 • The specifications for the gap width of typical automotive spark plug is approximately equal to the thickness of the cardboard used for matchbook covers. Because of the high compression of the air-gas mixture in the cylinder, the dielectric strength of the mixture is roughly 2.0×10^7 V/m. Estimate the maximum potential difference across the spark gap during operating conditions.

Picture the Problem The potential difference between the electrodes of the spark plug is the product of the electric field in the gap and the separation of the electrodes. We'll assume that the separation of the electrodes is 1.0 mm.

Express the potential difference between the electrodes of the spark plug as a function of their separation d and electric field E between them:

$$V = Ed$$

Substitute numerical values and evaluate V:

$$V = \left(2.0\times10^{7}\ \text{V/m}\right)\left(1.0\times10^{-3}\ \text{m}\right) = \boxed{20\,\text{kV}}$$

15 •• The radius of a proton is approximately 1.0×10^{-15} m. Suppose two protons having equal and opposite momenta undergo a head-on collision. Estimate the minimum kinetic energy (in MeV) required by each proton to allow the protons to overcome electrostatic repulsion and collide. *Hint: The rest energy of a proton is 938 MeV. If the kinetic energies of the protons are much less than this rest energy, then a non-relativistic calculation is justified.*

Picture the Problem We can use conservation of energy to relate the initial kinetic energy of the protons to their electrostatic potential energy when they have approached each other to the given "radius."

Apply conservation of energy to relate the initial kinetic energy of the protons to their electrostatic potential when they are separated by a distance r:

$$K_i + U_i = K_f + U_f$$

or, because $U_i = K_f = 0$,

$$K_i = U_f$$

Because each proton has kinetic energy K:

$$2K = \frac{ke^2}{r} \Rightarrow K = \frac{ke^2}{2r}$$

Substitute numerical values and evaluate K:

$$K = \frac{\left(8.988\times10^9\ \frac{\mathrm{N\cdot m^2}}{\mathrm{C^2}}\right)\left(1.602\times10^{-19}\ \mathrm{C}\right)^2}{2\left(1.0\times10^{-15}\ \mathrm{m}\right)} = 1.153\times10^{-13}\ \mathrm{J}\times\frac{1\,\mathrm{eV}}{1.602\times10^{-19}\ \mathrm{J}}$$

$$= \boxed{0.72\,\mathrm{MeV}}$$

Remarks: Because the kinetic energies of the protons is approximately 0.08% of their rest energy ($\mathbf{K/E_{rest} = 0.72\,MeV/938\,MeV \approx 0.08\%}$,) the non-relativistic calculation was justified.

16 • When you touch a friend after walking across a rug on a dry day, you typically draw a spark of about 2.0 mm. Estimate the potential difference between you and your friend just before the spark.

Picture the Problem The magnitude of the electric field for which dielectric breakdown occurs in air is about 3.0 MV/m. We can estimate the potential difference between you and your friend from the product of the length of the spark and the dielectric constant of air.

Express the product of the length of the spark and the dielectric constant of air:

$$V = (3.0\,\mathrm{MV/m})(2.0\,\mathrm{mm}) = \boxed{6.0\,\mathrm{kV}}$$

17 • Estimate the maximum surface charge density that can exist at the end of a sharp lightning rod so that no dielectric breakdown of air occurs.

Picture the Problem The maximum electric field E_{max} just outside the end of the lightning rod is related to the maximum surface charge density σ_{max}.

Express the maximum electric field just outside the end of the lightning rod as a function of the maximum surface charge density σ_{max}:

$$E_{max} = \frac{\sigma_{max}}{\epsilon_0} \Rightarrow \sigma_{max} = \epsilon_0 E_{max}$$

Substitute numerical values and evaluate σ_{max}:

$$\sigma_{max} = \left(8.854\times10^{-12}\,\frac{C^2}{N\cdot m^2}\right)\left(3.0\times10^6\,\frac{V}{m}\right) \approx \boxed{27\,\mu C/m^2}$$

18 •• The electric-field strength near the surface of Earth is about 300 V/m. (*a*) Estimate the magnitude of the charge density on the surface of Earth. (*b*) Estimate the total charge on Earth. (*c*) What is value of the electric potential at Earth′s surface? (Assume the potential is zero at infinity.) (*d*) If all Earth′s electrostatic potential energy could be harnessed and converted to electric energy at reasonable efficiency, how long could it be used to run the consumer households in the United States? Assume the average American household consumes about 500 kW·h of electric energy per month.

Picture the Problem (*a*) The charge density is the product of ϵ_0 and the magnitude of the electric field at the surface of Earth. (*b*) The total charge on Earth is the product of its surface charge density and its area. (*c*) The electric potential at Earth's surface is given by $V = kQ/R$ where Q is the charge on Earth and R is its radius. (*d*) We can estimate how long Earth's electrostatic energy could run households in the United States by dividing the energy available by the rate of consumption of electrical energy.

(*a*) The magnitude of the charge density σ on the surface of Earth is proportional to the electric field strength E at the surface of Earth:

$$\sigma = \epsilon_0 E$$

Substitute numerical values and evaluate σ:

$$\sigma = \left(8.854\times10^{-12}\,\frac{C^2}{N\cdot m^2}\right)\left(300\,\frac{V}{m}\right) = \boxed{2.66\,nC/m^2}$$

(*b*) The total charge on Earth is given by:

$$Q = \sigma A = 4\pi\sigma R^2$$

Substitute numerical values and evaluate Q:

$$Q = 4\pi\left(2.656\,\frac{\text{nC}}{\text{m}^2}\right)(6370\text{ km})^2 = \boxed{1.35\text{ MC}}$$

(c) The electric potential V at the surface of Earth is given by:

$$V = \frac{kQ}{R}$$

where R is the radius of Earth.

Multiplying and dividing by R and substituting for kQ/R^2 yields:

$$V = \frac{kQ}{R} = \left(\frac{kQ}{R^2}\right)R = ER$$

Substitute numerical values and evaluate V:

$$V = \left(300\,\frac{\text{V}}{\text{m}}\right)(6370\text{ km}) = \boxed{1.91\text{ GV}}$$

(d) Express the available energy:

$$E_{\text{avail}} = eU = e\left(\tfrac{1}{2}QV\right)$$

where e is the efficiency of energy conversion.

Assuming an efficiency of 1/3 yields:

$$E_{\text{avail}} = \tfrac{1}{3}\left(\tfrac{1}{2}QV\right) = \tfrac{1}{6}QV$$

Express the rate at which energy must be supplied to households in the United States:

$$P_{\text{req}} = P_{\substack{\text{req per}\\ \text{household}}} N_{\text{households}}$$

Assuming 80 million households in the United States, substitute numerical values and evaluate the lifetime of the electrical energy derived from Earth's electrostatic energy:

$$\frac{E_{\text{avail}}}{P_{\text{req}}} = \frac{\frac{1}{6}QV}{P_{\substack{\text{req per}\\ \text{household}}} N_{\text{households}}}$$

$$= \frac{(1.35\text{ MC})(1.91\text{ GV})}{6\left(500\,\dfrac{\text{kWh}\times\dfrac{3600\text{ s}}{\text{h}}}{\text{household}\cdot\text{month}}\times\dfrac{1\text{ month}}{30.4\text{ d}}\times\dfrac{1\text{ d}}{24\text{ h}}\right)\left(80\times10^{6}\text{ households}\right)}$$

$$\approx \boxed{2.2\text{ h}}$$

Electrostatic Potential Difference, Electrostatic Energy and Electric Field

19 • A point particle has a charge equal to +2.00 μC and is fixed at the origin. (*a*) What is the electric potential *V* at a point 4.00 m from the origin assuming that $V = 0$ at infinity? (*b*) How much work must be done to bring a second point particle that has a charge of +3.00 μC from infinity to a distance of 4.00 m from the +2.00-μC charge?

Picture the Problem The Coulomb potential at a distance *r* from the origin relative to $V = 0$ at infinity is given by $V = kq/r$ where *q* is the charge at the origin. The work that must be done by an outside agent to bring a charge from infinity to a position a distance *r* from the origin is the product of the magnitude of the charge and the potential difference due to the charge at the origin.

(*a*) The Coulomb potential of the charge is given by:

$$V = \frac{kq}{r}$$

Substitute numerical values and evaluate *V*:

$$V = \frac{\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(2.00\ \mu\text{C}\right)}{4.00\,\text{m}}$$

$$= 4.494\ \text{kV} = \boxed{4.49\,\text{kV}}$$

(*b*) The work that must be done is given by:

$$W = q\Delta V$$

Substitute numerical values and evaluate *W*:

$$W = \left(3.00\,\mu\text{C}\right)\left(4.494\,\text{kV}\right) = \boxed{13.5\,\text{mJ}}$$

20 •• The facing surfaces of two large parallel conducting plates separated by 10.0 cm have uniform surface charge densities that are equal in magnitude but opposite in sign. The difference in potential between the plates is 500 V. (*a*) Is the positive or the negative plate at the higher potential? (*b*) What is the magnitude of the electric field between the plates? (*c*) An electron is released from rest next to the negatively charged surface. Find the work done by the electric field on the electron as the electron moves from the release point to the positive plate. Express your answer in both electron volts and joules. (*d*) What is the change in potential energy of the electron when it moves from the release point plate to the positive plate? (*e*) What is its kinetic energy when it reaches the positive plate?

Picture the Problem Because the electric field is uniform, we can find its magnitude from $E = \Delta V/\Delta x$. We can find the work done by the electric field on the electron from the difference in potential between the plates and the charge of the

electron and find the change in potential energy of the electron from the work done on it by the electric field. We can use conservation of energy to find the kinetic energy of the electron when it reaches the positive plate.

(*a*) Because the electric force on a test charge is away from the positive plate and toward the negative plate, the positive plate is at the higher potential.

(*b*) Express the magnitude of the electric field between the plates in terms of their separation and the potential difference between them:

$$E = \frac{\Delta V}{\Delta x} = \frac{500\,\text{V}}{0.100\,\text{m}} = \boxed{5.00\,\text{kV/m}}$$

(*c*) Relate the work done by the electric field on the electron to the difference in potential between the plates and the charge of the electron:

$$W = q\Delta V = \left(1.602\times10^{-19}\,\text{C}\right)\left(500\text{V}\right) = \boxed{8.01\times10^{-17}\,\text{J}}$$

Converting 8.01×10^{-17} J to eV yields:

$$W = \left(8.01\times10^{-17}\,\text{J}\right)\left(\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}\right) = \boxed{500\,\text{eV}}$$

(*d*) Relate the change in potential energy of the electron to the work done on it as it moves from the negative plate to the positive plate:

$$\Delta U = -W = \boxed{-500\,\text{eV}}$$

(*e*) Apply conservation of energy to obtain:

$$\Delta K = -\Delta U = \boxed{500\,\text{eV}}$$

21 •• A uniform electric field that has a magnitude 2.00 kV/m points in the $+x$ direction. (*a*) What is the electric potential difference between the $x = 0.00$ m plane and the $x = 4.00$ m plane? A point particle that has a charge of $+3.00\ \mu$C is released from rest at the origin. (*b*) What is the change in the electric potential energy of the particle as it travels from the $x = 0.00$ m plane to the $x = 4.00$ m plane? (*c*) What is the kinetic energy of the particle when it arrives at the $x = 4.00$ m plane? (*d*) Find the expression for the electric potential $V(x)$ if its value is chosen to be zero at $x = 0$.

Picture the Problem (*a*) and (*b*) We can use the definition of potential difference to find the potential difference $V(4.00\text{ m}) - V(0)$ and (*c*) conservation of energy to find the kinetic energy of the charge when it is at $x = 4.00$ m. (*d*) We can find $V(x)$ if $V(x)$ is assigned various values at various positions from the definition of potential difference.

(*a*) Apply the definition of finite potential difference to obtain:

$$V(4.00\,\text{m}) - V(0) = -\int_a^b \vec{E}\cdot d\vec{\ell} = -\int_0^{4.00\,\text{m}} E d\ell = -(2.00\,\text{kN/C})(4.00\,\text{m}) = \boxed{-8.00\,\text{kV}}$$

(*b*) By definition, ΔU is given by:

$$\Delta U = q\Delta V = (3.00\,\mu\text{C})(-8.00\,\text{kV}) = \boxed{-24.0\,\text{mJ}}$$

(*c*) Use conservation of energy to relate ΔU and ΔK:

$$\Delta K + \Delta U = 0$$

or

$$K_{4\text{m}} - K_0 + \Delta U = 0$$

Because $K_0 = 0$:

$$K_{4\text{m}} = -\Delta U = \boxed{24.0\,\text{mJ}}$$

Use the definition of finite potential difference to obtain:

$$V(x) - V(x_0) = -E_x(x - x_0) = -(2.00\,\text{kV/m})(x - x_0)$$

(*d*) For $V(0) = 0$:

$$V(x) - 0 = -(2.00\,\text{kV/m})(x - 0)$$

or

$$V(x) = \boxed{-(2.00\,\text{kV/m})x}$$

22 •• In a potassium chloride molecule the distance between the potassium ion (K^+) and the chlorine ion (Cl^-) in a potassium chloride molecule is 2.80×10^{-10} m. (*a*) Calculate the energy (in eV) required to separate the two ions to an infinite distance apart. (Model the two ions as two point particles initially at rest.) (*b*) If twice the energy determined in Part (*a*) is actually supplied, what is the total amount of kinetic energy that the two ions have when they were an infinite distance apart?

Picture the Problem In general, the work done by an external agent in separating the two ions changes both their kinetic and potential energies. Here we're assuming that they are at rest initially and that they will be at rest when they are infinitely far apart. Because their potential energy is also zero when they are infinitely far apart, the energy W_{ext} required to separate the ions to an infinite

distance apart is the negative of their potential energy when they are a distance r apart.

(a) Express the energy required to separate the ions in terms of the work required by an external agent to bring about this separation:

$$W_{\text{ext}} = \Delta K + \Delta U = 0 - U_{\text{i}}$$
$$= -\frac{kq_{-}q_{+}}{r} = -\frac{k(-e)e}{r} = \frac{ke^2}{r}$$

Substitute numerical values and evaluate W_{ext}:

$$W_{\text{ext}} = \frac{(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.602\times10^{-19}\ \text{C})^2}{2.80\times10^{-10}\ \text{m}} = 8.238\times10^{-19}\ \text{J}$$

Convert this energy to eV:

$$W_{\text{ext}} = (8.238\times10^{-19}\ \text{J})\left(\frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}}\right)$$
$$= \boxed{5.14\,\text{eV}}$$

(b) Apply the work-energy theorem to the system of ions to obtain:

$$2W_{\text{ext}} = \Delta K + \Delta U = K_{\text{f}} - U_{\text{i}}$$

where K_{f} is the kinetic energy of the ions when they are an infinite distance apart.

Solving for K_{f} yields:

$$K_{\text{f}} = 2W_{\text{ext}} + U_{\text{i}}$$

From Part (a), $U_{\text{i}} = -W_{\text{ext}}$:

$$K_{\text{f}} = 2W_{\text{ext}} - W_{\text{ext}} = W_{\text{ext}} = \boxed{5.14\,\text{eV}}$$

23 •• [SSM] Protons are released from rest in a Van de Graaff accelerator system. The protons initially are located where the electrical potential has a value of 5.00 MV and then they travel through a vacuum to a region where the potential is zero. (a) Find the final speed of these protons. (b) Find the accelerating electric-field strength if the potential changed *uniformly* over a distance of 2.00 m.

Picture the Problem We can find the final speeds of the protons from the potential difference through which they are accelerated and use $E = \Delta V/\Delta x$ to find the accelerating electric field.

(a) Apply the work-kinetic energy theorem to the accelerated protons:

$$W = \Delta K = K_{\text{f}} \Rightarrow e\Delta V = \tfrac{1}{2}mv^2$$

Solve for v to obtain:

$$v=\sqrt{\frac{2e\Delta V}{m}}$$

Substitute numerical values and evaluate v:

$$v=\sqrt{\frac{2\left(1.602\times10^{-19}\ \text{C}\right)\left(5.00\,\text{MV}\right)}{1.673\times10^{-27}\ \text{kg}}}$$

$$=\boxed{3.09\times10^{7}\ \text{m/s}}$$

(b) Assuming the same potential change occurred *uniformly* over the distance of 2.00 m, we can use the relationship between E, ΔV, and Δx express and evaluate E:

$$E=\frac{\Delta V}{\Delta x}=\frac{5.00\,\text{MV}}{2.00\,\text{m}}=\boxed{2.50\,\text{MV/m}}$$

24 •• The picture tube of a television set was, until recently, invariably a cathode-ray tube. In a typical cathode-ray tube, an electron "gun" arrangement is used to accelerate electrons from rest to the screen. The electrons are accelerated through a potential difference of 30.0 kV. (a) Which region is at a higher electric potential, the screen or the electron's starting location? Explain your answer. (b) What is the kinetic energy (in both eV and joules) of an electron as it reaches the screen?

Picture the Problem The work done on the electrons by the electric field changes their kinetic energy. Hence we can use the work-kinetic energy theorem to find the kinetic energy and the speed of impact of the electrons.

(a) Because positively charged objects are accelerated from higher potential to lower potential regions, the screen must be at the higher electric potential to accelerate electrons toward it.

(b) Use the work-kinetic energy theorem to relate the work done by the electric field to the change in the kinetic energy of the electrons:

$$W=\Delta K=K_\text{f}$$

or

$$K_\text{f}=e\Delta V \qquad (1)$$

Substitute numerical values and evaluate K_f:

$$K_\text{f}=(1e)(30.0\,\text{kV})=\boxed{3.00\times10^{4}\ \text{eV}}$$

Convert this energy to eV:

$$K_\text{f}=\left(3.00\times10^{4}\ \text{eV}\right)\left(\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}\right)$$

$$=\boxed{4.81\times10^{-15}\ \text{J}}$$

25 ••• (*a*) A positively charged particle is on a trajectory to collide head-on with a massive positively charge nucleus that is initially at rest The particle initially has kinetic energy K_i. In addition, the particle is initially far from the nucleus. Derive an expression for the distance of closest approach. Your expression should be in terms of the initial kinetic energy K of the particle, the charge ze on the particle, and the charge Ze on the nucleus, where both z and Z are integers. (*b*) Find the numerical value for the distance of closest approach between a 5.00 MeV α-particle and between a 9.00 MeV α-particle and a stationary gold nucleus. (The values 5.00 MeV and 9.00 MeV are the initial kinetic energies of the alpha particles. Neglect the motion of the gold nucleus following the collisions.) (*c*) The radius of the gold nucleus is about 7×10^{-15} m. If α-particles approach the nucleus closer than 7×10^{-15} m, they experience the strong nuclear force in addition to the electric force of repulsion. In the early 20th century, before the strong nuclear force was known, Ernest Rutherford bombarded gold nuclei with α-particles that had kinetic energies of about 5 MeV. Would you expect this experiment to reveal the existence of this strong nuclear force? Explain your answer.

Picture the Problem We know that energy is conserved in the interaction between the α particle and the massive nucleus. Under the assumption that the recoil of the massive nucleus is negligible, we know that the initial kinetic energy of the α particle will be transformed into potential energy of the two-body system when the particles are at their distance of closest approach.

(*a*) Apply conservation of energy to the system consisting of the positively charged particle and the massive nucleus:

$$\Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0$$

Because $K_f = U_i = 0$:

$$-K_i + U_f = 0$$

Letting r be the separation of the particles at closest approach, express U_f:

$$U_f = \frac{kq_{\text{nucleus}}q_{\text{particle}}}{r} = \frac{k(Ze)(ze)}{r} = \frac{kzZe^2}{r}$$

Substitute for U_f to obtain:

$$-K_i + \frac{kzZe^2}{r} = 0 \Rightarrow r = \boxed{\frac{kzZe^2}{K_i}}$$

(*b*) For a 5.00-MeV α particle and a stationary gold nucleus:

$$r_5 = \frac{(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2)(79)(1.602\times10^{-19}\ \text{C})^2}{(5.00\,\text{MeV})(1.602\times10^{-19}\ \text{J/eV})} = \boxed{46\ \text{fm}}$$

For a 9.00-MeV α particle and a stationary gold nucleus:

$$r_9 = \frac{\left(8.988\times10^{9}\ \mathrm{N\cdot m^2/C^2}\right)(2)(79)\left(1.602\times10^{-19}\ \mathrm{C}\right)^2}{(9.00\,\mathrm{MeV})\left(1.602\times10^{-19}\ \mathrm{J/eV}\right)} = \boxed{25\ \mathrm{fm}}$$

(*c*) No. The distance of closest approach for a 5-MeV alpha particle found above (46 fm) is much larger than the 7 fm radius of a gold nucleus. Hence the scattering was solely the result of the inverse-square Coulomb force.

Potential Due to a System of Point Charges

26 • Four point charges, each having a magnitude of 2.00 μC, are fixed at the corners of a square whose edges are 4.00-mlong. Find the electric potential at the center of the square if (*a*) all the charges are positive, (*b*) three of the charges are positive and one charge is negative, and (*c*) two charges are positive and two charges are negative. (Assume the potential is zero very far from all charges.)

Picture the Problem Let the numerals 1, 2, 3, and 4 denote the charges at the four corners of square and r the distance from each charge to the center of the square. The potential at the center of square is the algebraic sum of the potentials due to the four charges.
